"After all that has been written on the old and newer processes for detecting arsenic, I must nevertheless avow my conviction, that, for solid arsenic, no test is, for medico-legal purposes, at once so satisfactory, convenient, and delicate, as the test of reduction, especially with the addition of the supplementary test of oxidation. That other methods are still more delicate, may be readily granted. But where the suspected substance is in the solid form, what possible occasion can there be for a method more delicate than one which will detect a 300th part of a grain? A method ten times less so, would meet every case in actual practice. A variety of supplementary tests have been proposed; but they are all greatly inferior in facility or conclusiveness, or both, to the process of oxidation, and ought therefore to be expelled from medico-legal practice,—not even excepting the alliaceous odour of metallic arsenic in subliming, a character the fallaciousness of which was long ago pointed out by myself as well as others, and to which a preposterous importance has been attached in some late inquiries." (p. 261.)

In speaking of Renisch's process, Dr. Christison recommends that the metallic copper should not be introduced into the diluted muriatic acid until this

has nearly reached the boiling point, because the metal is otherwise apt to become tarnished, although no arsenic be present. In respect to the detection of arsenic in the tissues of the body, he recommends the process pursued by MM. Danger and Flandin; that is, carbonization by sulphuric acid, in preference to incineration with nitre, as recommended by Orfila. The chapter on arsenic is of itself a perfect treatise, embracing all that is practical and useful to the medical jurist in relation to this poison.

The author's recent researches on the action of various kinds of water on lead are incorporated in the chapter devoted to that metal, and form a useful addition to the subject of medical police.

That Dr. Christison has not lost sight of the latest additions to toxicology, is proved by his reference to the new antidote for prussic acid, recommended a few months since by the Messrs. Smith, of Edinburgh: we allude to the mixed oxides of iron, which have the property of converting the poison to insoluble Prussian blue. In addition to this treatment, he recommends cold affusion to the head and spine, venesection at the jugular vein, and the inhalation of diluted ammonia and chlorine.

Many additions have been made to the chapter on poisonous gases, especially in relation to carbonic acid; and in the chapters on the narcotico-irritants, we notice among the additions, a full account of poisoning by labournum and the oleaginous products of combustion, including Dippel's oil, the oils of turpentine and of tar.

The subject of compound poisoning, which concludes the volume, is shortly discussed.

We are glad to perceive that, in treating the tests for poisons, the author prefers old terms and perspicuity of language to the pedantic allusions of modern chemistry, that is, the display of symbols and formulæ as substitutes for description. Dr. Christison has so written, that he may be understood both by the lawyer and the medical practitioner; his descriptions are, besides, equally intelligible to those who studied chemistry fifteen and twenty years ago, and the modern race of students, who are now taught to speak and think in symbols and

algebraic formulæ,—and to decide chemical decompositions by equations instead of by actual experiment, thereby losing the substance for the shadow. Some hypercritics may object to the author retaining in this, the year 1845, the old fashioned names of hydrochlorate of lime, ferrocyanate of potash, and carbonate of ammonia, instead of chloride of calcium, ferrocyanide of potassium, and sesquicarbonate of the oxide of ammonium. For the reasons already stated, we do not object to this old nomenclature. With regard to the chloride doctrine, the theory of double decomposition between the hydracid and base is doubtless more simple; but the simplicity of a theory is not necessarily a sure guarantee of its truth. Hydrochloric acid combines directly with morphia: no one has hitherto pretended that the hydrogen of the acid combines with one equivalent of oxygen of the alkaloid; yet why not assume this for the sake of simplicity and uniformity? So ferrocyanide of potassium may really be ferrocyanate of potash. Not many years ago its congener, Prussian blue, was regarded as ferrocyanide of iron; it is now considered as a ferrocyanate of the peroxide; for it cannot lose the elements of water without decomposition. Again, it is somewhat inconsistent to maintain the existence of a sesquicarbonate of oxide of ammonium, when it is utterly impossible that there can be a simple carbonate of that alleged oxide; since the simple carbonate is immediately decomposed by water. Thus, then, carbonic acid may combine in single equivalents with the alkaline base, ammonia; but in any other proportion, carbonic acid is assumed to determine the transference of the hydrogen of one equivalent of water to the ammonia, forming ammonium, and producing an oxide with the remaining equivalent of oxygen! Such are the inconsistencies into which those are led, who are desirous of maintaining, at all costs, a favourite theory.

We have been drawn into this digression, because the retention of the old nomenclature might be objected to as a defect in the present edition: if we remember rightly, this objection was actually made to the earlier editions of the treatise. We do not hesitate to say, that Dr. Christison has shewn both judgment and good sense

in retaining it; and we shall now conclude by observing, that the fourth edition is well calculated to uphold the high reputation of its author.

Guy's Hospital Reports. Second Series.
No. IV. Oct. 1844.

(Second Analytical Notice.)

MR. J. P. FRANCE, the Assistant-Surgeon to the ophthalmic department of Guy's Hospital, furnishes a detailed account of eighteen cases of iritis, for the purpose of illustrating points in the pathology and treatment of that complaint. In fifteen of these sight was restored, two applied too late to receive the full benefit of medicine, and in the remaining one the wretched intemperance of the patient precluded all hope of success. As these cases were not selected for their peculiar success, Mr. France expresses his belief that there is no disease of so serious and disorganizing a character, when allowed to proceed unchecked, which is so completely and unequivocally amenable to early and well directed remedial treatment as this. He adopts the threefold division of iritis, which has been founded upon constitutional grounds, viz. the rheumatic or arthritic, the syphilitic, and the simple kinds, as the correct one; and, in truth, the paper is principally written to illustrate and vindicate the separation of the syphilitic from the arthritic variety. With reference to the comparative frequency of the three, he observes, that the simple, as a primary affection, independent of wound or injury, is very rare, while "persons labouring under syphilis form about one-half, perhaps more, of the whole number of cases who present themselves the subject of this disease." In the majority of cases of arthritic iritis, according to Mr. France, the lining of the anterior chamber and serous covering of the iris, in common with the sclerotic, are the principal seat of the disease, herein closely agreeing "with the recognised disposition of rheumatic inflammation in other regions to affect free membranous surfaces (as those of the synovial cavities and pericardium), and then give rise to abundant effusion, which is unknown as an accompaniment of rheumatism of fibrous and muscular tissue. Thus the large participation of the aqueous membrane in the inflammation called arthritic iritis, is mani-

festated by copious effusion into its cavity, generally fibrinous, but sometimes serous; while the affection of the muscular structure is inferred only from its proximity, the contracted pupil, aching pain, and especially the exacerbation of that pain occasionally produced by the application of belladonna. Syphilitic iritis, on the contrary, is for the most part essentially an inflammation of the parenchymatous structure; and to this circumstance the disease owes its peculiar character of producing tumefaction or thickening; and in proportion as it departs from this type, are the chief marks deemed diagnostic either ill developed or absent." The tubercles generally regarded as attachments of lymph to the free surface of the iris, are explained as "irregularities of the surface of the iris, due to its proper substance being at certain parts swollen and infiltrated." At first these swollen portions barely rise above the surrounding level; but owing to the loose and distensible texture of the iris any part may become elevated, so as to constitute a tubercle projecting high above the general plane, and sometimes even overlapping its own base." The following passage we give in the exact words of the author.

"Simultaneously with local tumefaction, a rusty reddish-brown colour is most frequently assumed at the same points, especially in irides naturally hazel or brown; and it arises from one or more vessels distended with red blood ramifying in the aqueous membrane over those inflamed points. Not quite so soon as the colour appears is the source whence it springs perceptible by the eye; a certain degree of inflammatory excitement must first be attained; in other words, the distension and dilatation of those minute vessels must reach a certain pitch before they can be recognized, even with artificial aids. In moderately severe cases this soon takes place; and if then the eye be inspected closely in a good light, and with the assistance of a powerful lens (the cornea and aqueous membrane being clear, and photophobia not great) sometimes only one or two, but occasionally a complete network of vessels becomes manifest, ramifying over the swollen parts of the iris, and evidently imparting to them the rusty red colour they exhibit." (This observation the author believes

to be original). "The appearances I now describe may be detected in so large a proportion of cases where this dusky colour is developed, that I cannot doubt that the same hue arises from the same causes when from the mildness of the attack, and the consequent slighter vascular distension, the individual vessels elude observation, or intolerance of light forbids that close examination, and exposure of the globe which are necessary in most cases for their recognition. In some rare cases these vessels are so gorged, crossing over a well-grown tubercle, that the naked eye can scarcely fail to notice them: in such instances they have in fact been observed, and been ascribed to organization having taken place in lymph thrown out into the anterior chamber from the free surface of the iris. To this hypothesis, though sanctioned by very high authority, I must object that it is at variance with the results of early and patient investigation, and with analogy; for fibrin effused during an attack of peritonitis or pleuritis, or even rheumatic iritis, is not endowed with appreciable vascularity until after the lapse of a lengthened period; not, in short, until all active disease has subsided; and lastly, it is opposed to all experience that a structure once so fully organized should disappear and be removed in a few days by the influence of any remedy, even so powerful a one as mercury. It is on the other hand worthy of remark, in connection with this part of the subject, that in other instances one grand character of the action of the true syphilitic virus seems to be the development of disease, whether marked by ulceration or effusion in the cellular tissue or parenchyma of organs—examples of which may be adduced in the so-called Hunterian chancre, surrounded by abundant but circumscribed fibrinous interstitial effusion; in nodes; in the tuberculated forms of syphilitic cutaneous eruption; in the disease known as chronic carbuncle, or, *par excellence*, cellular membranous ulcer (ordinarily of syphilitic origin); syphilitic ulcers of the throat, again, are partly recognized by their extending into the substance of the tonsil, &c."

Mr. T. Wilkinson King publishes the description of a specimen of partial fracture of the neck of the thigh bone, and also of the nutritive artery of the epi-

physial bone, forming the head of the femur, illustrated by two plates, with the view of directing attention to the influence which the integrity or laceration of this vessel may exert over the *rezata questio* of bony union of fractures of this part. The following is his description. "The artery which supplies the head of the femur, while it constitutes an epiphysis, is persistent through life. It is a large terminal branch of the internal circumflex artery, which enters a foramen a little behind and below the highest point of the neck of the femur. After this it curves over the denser layer of cancelli left by the union of the epiphysis to the shaft, directing its course beyond the insertion of the round ligament, to which, I doubt not, it furnishes nourishment. Now it is remarkable that this vessel occupies the situation of the greatest immunity from violence; and that if only a little periosteum about it escape division, when complete fracture occurs, it may be left entire to sustain that which I think could hardly live without it. This consideration seems corroborated by all the examples I have examined of ligamentous union after fracture of this part. Whether there be a reunion by solid ligament, by a few scattered bands, or by a kind of capsule and cell (all rare events), I find the course of this vessel uninterrupted."

The next paper is supplementary to the very valuable communication on Paracentesis Thoracis, by Dr. Hughes, and Mr. Cock, of which we formerly gave such an extended notice. It contains an account, in detail, of three cases in which the operation has been performed since the former paper was written, and which, with two cases then inadvertently omitted, have been added to the tabular view of twenty cases there appended. "Of the twenty-five cases," Dr. Hughes observes, "in which paracentesis thoracis was once, or several times performed, thirteen may be fairly stated to have recovered, so far as regards the effusion into the pleural cavity. Two may be justly mentioned as having at least partially recovered. One of these has, after seven years, a fistulous opening into the pleura; and the other has still some, though comparatively a very small quantity of fluid in the right pleura;

but feels so much better as to be actually in search of employment in his profession. Ten have *ultimately* died of other diseases, generally connected with that for which the operation was performed, but entirely independent of its performance. Of these ten cases ultimately fatal, six have died of phthisis; one of gangrenous pulmonary abscess of the opposite side; one after three months of chronic pneumonia; one, rather suddenly, with hydrothorax in the other pleura; and one, a case of pneumo-thorax with effusion (in which the operation was performed simply with the hope of affording temporary relief) of pneumonia and pericarditis."

MEDICAL GAZETTE.

Friday, January 3, 1845.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

ADVANTAGES

OF A

WELL-CONSTITUTED COUNCIL OF HEALTH AND EDUCATION.

THE past year has been distinguished as one of incessant turmoil and agitation in the medical world—we should fain hope that the present may be one of peace and quietness. The art of medicine has been emphatically styled a domestic art, and so it is in point of fact. Accordingly, all open manifestations of strife and dissension must infallibly tend to lower its professors in general estimation, and to impair their influence and usefulness. The public naturally feel that the sick chamber will suffer neglect when much time and attention are devoted to meetings of associations and the like.

We have strenuously advocated the importance and necessity of great alterations as regards the medical polity of our fatherland, and have ventured to promulge a scheme of reform which we

are confident will meet the approbation of all parties.

The welfare of a people is the supreme law. It therefore behoves a minister of the crown, in all questions touching the health and lives of Her Majesty's lieges, to see that such legislative enactments are introduced as shall conduce to the universal good. Nor do we despair of this being the event. Indeed, we have no hesitation in declaring our firm belief that a Council of Health and Education, appointed by the Home Secretary of State, independently of all corporate bodies connected with the science and practice of medicine, in each and every one of its departments, would be fraught with signal advantages, not only to the members of the healing art, but to the community at large. It will, of course, be in the province of the minister, or of his Council, to assign a curriculum, and that curriculum, we have no doubt, will be carefully adapted to the exigencies of the times. The same sound discretion and judgment will be exercised in selecting competent examiners as is uniformly displayed in the choice of the officers of the law or the dignitaries of the church. On this head we are inclined to augur most favourably.

The practitioner armed with the state license may pursue his vocation where he will and as he will. He may adopt a general line of practice, or present himself for the Fellowship of the College of Surgeons; or, having obtained a degree at some University, eventually become a Fellow of the College of Physicians.

We repudiate all authority based solely upon adventitious distinctions among well-educated and industrious men. We look upon our brethren as offsets from one common trunk. We moreover maintain that as there is but one law for rich and poor, so ought

there to be virtually but one license throughout the realm for every practitioner of physie, be his sphere of activity among the affluent and high-born, or among the lowly and indigent. The highest of all authority proclaims that "the poor shall never cease out of the land;" and if it be the sacred duty of rulers to ordain some adequate provision for their spiritual and temporal wants, it is a part of that duty to see that their infirmities of body and mind shall be ministered to by persons of warranted skill and experience. We anticipate much benefit from such a system of things. So far from degrading, it will tend to elevate the medical man in the social scale. It will raise him from the somewhat equivocal position he now holds, to one of unquestioned respectability.

Again: the paternal care thus manifested by those in authority, will, we think, dispose materially to abate the prevailing disaffection of the labouring classes. It cannot fail to be a matter of satisfaction and comfort to the humble artizan, to know, that in the languishing hours of sickness and of pain, he can seek for advice and relief at a source equally efficient with the first person in the land; nay, that the very individual to whom he applies possesses the same qualification, and derives it indirectly from the crown.

We conceive the claims of the general practitioners are entitled to paramount consideration; for them as a body we entertain the utmost respect; we view them as constituting the largest, and, as regards the public, by far the most important branch of our profession; and we boldly assert, that any measure which would tend to deteriorate their education, and to degrade their station in society, would be productive of most baleful consequences. The community would be inundated with a flood of half-educated and

skillless individuals of the "baser sort"—pettifogging traffickers, reckless of human life, swayed by no other consideration save that of sordid gain. Physicians and surgeons would, ere long, sink to the vulgar level of their brethren in certain countries of Continental Europe. Emolument would decline, and, at the same time, all incentive to the pursuit of knowledge and distinction, until none of respectability would be found willing to enter a *craft* so thoroughly debased. Such a consummation, however, we are sure can never arrive. The British senate will never give its sanction to any act capable of inducing such pernicious changes.

DANCING OVER THE DEAD.

WE have been long familiar with the "Dance of Death," but never knew that dancing over the dead had been practised in a civilised land, until our attention was pointed to the fact by a printed paper of Mr. Walker, the unwearied assailant of the grave-yard nuisance in crowded towns.

It appears that on the western side of Clement's Lane, Strand, is situate a building called Enon Chapel, surrounded on all sides by houses, crowded with inhabitants, principally of the poorer class. The upper part of this edifice was opened for the purposes of public worship about 1823. It is separated from the lower part by a boarded floor: this was used as a burying-place, and crammed at one end even to the top of the ceiling with dead. It is estimated that within this space, not exceeding 1700 square feet, from ten to twelve thousand corpses have been deposited during the period of sixteen years. The chapel has been latterly converted into what is called a Temperance Hall, in which plain and fancy dress balls are held: an efficient band is engaged, and quadrilles, waltzes, reels, &c. are danced over the masses of mortality in the charnel-house beneath.

MOVEMENT IN THE PROFESSION.

A GENERAL meeting of the medical practitioners of the northern division of Cheshire was held in the board-room of the Stockport Infirmary, on the 12th ult.: Dr. Turner in the chair. The "Bill for the better Regulation of the Medical Profession" was generally approved, though dissent was expressed as to some of its enactments. The proposed constitution of the Council of Health was impugned, inasmuch as the great body of general practitioners are not adequately represented. It was regretted that registration is not made compulsory; and that some summary process of punishment is not prescribed for preventing unqualified persons from practising medicine or surgery. It was suggested that Government should not lend its sanction to empiricism by granting patents for secret medicines.

On Monday evening last, a meeting took place of the Medical and Surgical Association of the Borough of Marylebone: John Propert, Esq. V.P. in the chair. It was agreed that this Association merge into the "National Association of General Practitioners in Medicine, Surgery, and Midwifery," as instituted at the Hanover Square Rooms on the 7th ult.; that the Treasurer and Hon. Secretary confer with the official agent of the above association for the purpose of enrolling new names; and that some substantial mark of respect, to the extent of subscriptions, be conveyed to the Hon. Secretary. No efforts are to be spared towards obtaining a "charter of incorporation for a College of General Practitioners in Medicine, Surgery, and Midwifery."

 PROTEST OF THE PRACTITIONERS OF SURREY.

WE, the undersigned, being Members of the Royal College of Surgeons, residing in the rural parts of Surrey, desire to record our earnest and indignant protest against the exclusion in which we are placed by the proceedings of the Council of the College, in the matter of the recent Charter.

We protest against the arbitrary elevation of a few gentlemen above those of their brethren, who were previously their equals

in professional rank, senior to many of them as Members of the College, and not inferior to most of them in scientific and practical knowledge.

We consider the invitation to the mass of the profession to undergo examination, in order to obtain the rank, which has thus been conceded to a select few, to be an affront, which if we remained silent under it, we might be considered to have deserved.

[In a private note we are informed that this protest "is signed by nearly the whole of the practitioners of the country parts of Surrey, who are Members of the College of Surgeons," and that "scarcely a single name of any respectable practitioner settled in the principal towns of the county is wanting.—ED. GAZ.]

"HOTEL-DIEU SURGERY."

To the Editor of the Medical Gazette.

SIR,

THE appearance, in your last number, of some appropriate remarks on hospital surgery (?) in Paris, tempts me to forward you the leading facts of three cases which fell under my own observation, and which, I venture to think, should convince our migratory students that as good surgery may be found on their own side of the Channel as among our more "peli-hed" neighbours. Though no notes were made at the time (1838), the cases themselves were sufficiently striking to leave an unfading impression on my mind; and as one of them occurred at the Hôtel-Dieu, and in the clinique of a surgeon who has published criticisms on English practice, I shall give it first.

A young man, in good health, but of delicate frame, was admitted with what was originally paronychia, though, at the time he entered the hospital, inflammation had extended to the wrist, and matter was already supposed to be forming under the palmar fascia. When I saw him there was no doubt as to the presence of matter there, yet no outlet was made for it. On the second day following, not only the hand but the forearm was involved, and pus had found its way under the annular ligament, which, by its inelasticity, acted like a ligature on the swollen parts. Mons. — now for the first time said, that "there was matter; that it was

deeply seated; and, in all probability, in contact with the radio-ulnar interosseous ligament." What might a few days previously have been discharged by a small puncture, now required a most fearful incision for its evacuation. The bistoury was produced, plunged deeply between the pronators and supinators of the forearm, and carried up rapidly from the wrist to the bend of the elbow; the arm fell open (I can use no other expression), and a pint of matter instantly escaped, but with it—from the brachial end of the wound—forcible and regular jets of florid blood. The nature of the accident was immediately apparent, and attempts were made to tie the wounded bifurcation of the brachial artery at its point of division. This was not accomplished, and it was therefore cut down upon in the usual place, and secured.

I left the hospital painfully impressed by reflections on the case. Surely, said I, "putting aside the accident which attended the case, and which was clearly the result of reckless carelessness in conducting the incision,—so celebrated a surgeon as M. — knew that the matter should have been evacuated as soon as its presence became apparent in the thumb;—or, was that operation not sufficiently *éclatant* for him?" I could not dispel the conviction that the mischief had been allowed to go on in order to afford *les étrangers* an opportunity of witnessing this *incision menstre*.

The sequel is still more melancholy. The mischief continued to advance; the poor fellow became hectic, and, when I left Paris, it was contemplated to remove the arm at the shoulder-joint.

Case 2 was at La Pitié, the patient a man *et. 45*, and the injury compound fracture and dislocation of the ankle-joint—such an one as to require, according to English notions, immediate amputation. Mons. — looking round the bed and seeing only four of us, postponed the operation until the following morning, remarking that "the attendance of students was too scanty." On the day following, being at the hospital before the arrival of Mons. —, I had an opportunity of examining the patient with the dressers. There were, in addition to the ill-conditioned wound, alarming constitutional symptoms, and a suspicious-looking discoloration on the calf of the leg. Mons. — came, and again postponed the operation, for the same reason (we were "only half a dozen"), scarcely glanced at the part as he passed by, and upon the blackness being pointed out to him declared it to be ecchymosis. The man died that evening with gangrene.

Case 3, also at La Pitié, was that of a

woman whom I saw operated on by the same surgeon for cancer of the left mamma. The disease was found to extend into the axilla, and the dissection was long and difficult in consequence. In three quarters of an hour Mons. — had removed several diseased glands, and in doing so had completely exposed the axillary vessels and nerves, so that they could be distinctly seen from the uppermost benches of the theatre—a bold as well as a skilful piece of work. But what happened next?—Each of the assistants, one by one, was allowed by the operator to handle the artery, and, with finger and thumb, to convince himself, by testing its pulsation, that his astonished and admiring eyes had not deceived him. I remarked to an Englishman at my side, a stranger to me, but whose eye this may meet, that there could be but one result to such barbarity. Two days afterwards her bed was vacant. I learned that she was dead, and, being unable to obtain more satisfactory information from the dressers, was led to conclude that there had been secondary hæmorrhage.

Now, it is rather because these cases are, all three of them, exemplificative of bad surgery, than on account of the barbarity which distinguished their treatment, that I transmit them to the *GAZETTE*. That the English student may derive much information from his attendance on French hospitals is not to be denied; that he may see here what he will never see in his own country is equally certain; but that the kind of information thus obtained, at the expense of his better feelings, can ever be useful to him as a philosophical, humane, and high-minded practitioner is very questionable. That the French are distinguished by their talent, and, above all, by their splendid contributions to medical science, I am ever ready to allow; that some of their surgical proceedings are attended with unlooked-for success is also true; but that their failures are as a hundred to one of these successes the experience of eye-witnesses can confirm. The quack, in our own country, because he is unscrupulous, occasionally works a cure which a recognised surgeon has declared unattainable. Preserve us, however, alike from the uneducated ruthlessness of the quack, and the refined and brilliant execution of the French hospital surgeon.

CHIRURGUS BRITANNICUS.

London, Dec. 19, 1844.

VACCINATION, RE-VACCINATION, SUSCEPTIBILITY TO SMALL-POX.

OF 139 persons attacked with small-pox in the course of eight years, in a district of Prussia, 47 had not been vaccinated and 92 had been vaccinated; of the unvaccinated 15 died, of the vaccinated 1 was lost. In addition to these, it was known that 121 persons who had been vaccinated were in immediate attendance upon the patients labouring under small-pox, without becoming affected.

The susceptibility to infection from small-pox appears to increase in a very regular progression, according to the number of years which have elapsed since the vaccination: at the end of the eleventh year the susceptibility to small-pox contagion is again very considerable; and it appears to reach its maximum after the sixteenth year. Almost the same progression as occurs in reference to the number of years since vaccination was performed, also occurs with reference to the more perfectly developed or severer forms of small-pox in the vaccinated: up to the fifteenth year not more than one-fourth of the vaccinated are severely affected; between the sixteenth and thirtieth years somewhat more than one-third, and after thirty years half of those attacked have small-pox in a severe form. This appears very distinctly in the following table:—

Vaccinated persons.	Years elapsed since the vaccination.	Milder forms of small-pox.	Severer forms of small-pox.
4	1 to 5 years.	3	1
7	6 „ 10 „	5	2
6	11 „ 15 „	5	1
17	16 „ 20 „	11	6
23	21 „ 25 „	15	8
23	26 „ 30 „	14	9
10	31 „ 35 „	5	5
2	36 „ 40 „	1	1
92		59	33

The following general conclusions may be drawn:—

1st. Re-vaccination as a general rule is well undertaken between sixteen and twenty years of age, inasmuch as during this period the susceptibility or resusceptibility to small-pox is greatest.

2d. From the ninth to the tenth year after the first vaccination, the susceptibility to be affected anew with the vaccine poison exists in a considerable degree: re-vaccination among children of ten years of age having a like amount of efficacy, being successful as

frequently as among older individuals.—*Dr. Schüffer, Medicinische Zeitung*. No. 13, 1844.

RESULTS OF THE

RE-VACCINATIONS PERFORMED IN THE PRUSSIAN ARMY IN THE YEAR 1843.

In this year the number of individuals vaccinated amounted to 42,998, of whom the number who had <i>distinct</i> traces of having been already vaccinated was . . .	34,390
Having <i>indistinct</i> traces . . .	6,258
Having no trace whatever . . .	2,350
Of the number vaccinated the cow-pock ran its course regularly in . . .	22,062
Irregularly in . . .	8,613
and in . . .	12,323
the vaccination was without an effect.	
In the latter number, vaccination was tried again with effect in . . .	2,439
Without effect in . . .	9,671

Of those who were vaccinated, or re-vaccinated with effect, in the course of this year 1843, there were attacked with varicella . . . 11
With varioloid . . . 8
With genuine small-pox . . . 4

It therefore appears that of the 42,998 individuals who were vaccinated or re-vaccinated in the Prussian army, in the course of the year 1843, 22,062 were done with such effect that genuine regular cow-pock followed the operation. Of 100 vaccinated or re-vaccinated, consequently, the protective pustule went through its regular course in somewhat more than 51, which is very nearly the proportion which was observed in the years 1841 and 1842.

In the course of the year 1843 small-pox prevailed epidemically over the Prussian monarchy; and the disease appeared with unusual frequency among the troops, 167 individuals having been attacked with small-pox in one shape or another in the course of the year; the disease shewing itself as varicella in 72, as varioloid in 80, and as unmitigated small-pox in 15.

Of the whole number of cases, 30 of varicella, 40 of varioloid, and 6 of genuine small-pox, 76 in all, occurred in individuals who had not been vaccinated; and again, 31 cases of varicella, 31 of varioloid, and 4 of genuine small-pox, occurred in individuals who had been once or twice subjected to re-vaccination in former years without effect; and 11 cases of varicella, 8 of varioloid, and 4 of true small-pox, as already stated, occurred in individuals who had been re-

vaccinated with success in the course of the year. Finally, two persons were attacked, one with varioloid, another with genuine small-pox, who had not been vaccinated in their youth, but who had at a later period gone through a former attack of small-pox, distinct evidences of which they still bore on their persons.

The disease in the 23 men re-vaccinated in the course of the year was mild and favourable, except in a single instance, in which death followed. Two other deaths occurred in the Prussian army from small-pox in the course of the year 1843; one in a man who had been vaccinated in the year 1842, the other in a man who had been re-vaccinated in 1843 without effect.—*Medicinische Zeitung*.

IMPERFORATE HYMEN.

M. L., aged 18, had complained for about two years of severe pains in the abdomen, and had lost her former blooming appearance, at the same time that her abdomen became enlarged—a circumstance which led at first to the suspicion of pregnancy, but which was soon ascertained to be unfounded. Various means having been tried to restore the catamenia, which had been suppressed, and the patient getting worse and worse, I was called into consultation. I found the patient emaciated, pallid, with a flush upon the cheek, frequency of pulse, and complaining of thirst and sleeplessness. She was asthmatic, and motion of every kind, particularly mounting a stair, was very distressing to her. The abdomen was distended as in the last period of pregnancy, uniform and tense, but without fluctuation. She had constant desire to make water, but only passed a few drops at a time without pain. Having no appetite, she took very little nourishment; nevertheless, the bowels were moved daily, she having a constant desire to go to stool. In doubt as to the nature of the case, I explored per vaginam, and immediately discovered that the hymen was completely imperforate, and had thus retained the menstrual fluid. I at once divided the hymen with a lancet, upon which about three pints of very fetid putrid blood, mixed with slime, escaped. The patient fainted, but on recovering declared herself relieved; and under the use of bark and wine, and the return of the regular menstrual discharge, soon recovered her former fresh appearance and her health.—*DR. REHFELD, Medicinische Zeitung*, No. 11, 1844.

RELATIONS, IN POINT OF WEIGHT, OF THE NERVOUS PARTS OF MAN AND SOME ANIMALS.

By M. BOURGERY.

THE particular object of the author's memoir was to determine the relations in absolute weight of the nervous organs of man and several mammalia, and to draw such conclusions as the facts naturally suggested. Proceeding thus, M. Bourgery finds that the mean weight of the encephalon, or central nervous mass, being 2393·5* grains troy; the cerebral hemispheres stand for 16940·46 grains of that quantity, the cerebellum for 2176·7 grains, the cephalic prolongation of the cerebro-spinal axis for 1312·2 grains, the optic thalami and corpora striata taking 879·9 grains; the medulla oblongata, with the pons Varolii, 432·2 grains; and the spinal marrow 710·1 grains. It follows from this that in man the cerebral hemispheres, the peculiar organs of psychological manifestation, include a nervous mass which, with reference to the other portions of the apparatus, is *four* times that of all the rest of the cerebro-spinal mass, *nine* times that of the cerebellum, the putative organ for the combination of voluntary motions, nearly *thirteen* times that of the cephalic stem of the spinal marrow—comprising the organs of the senses, with the exception of those of olfaction, those for the transmission of general sensibility, and those of respiration—and *twenty-four* times that of the spinal marrow, the cord for the conduction and incitation of the sensibility and motions of the whole body, the viscera included. This predominance of the cerebral hemispheres, so considerable in man, declines decidedly when we pass from man to those animals which most resemble him; and it diminishes gradually in these from the dog to the horse, cat, ox, and sheep; in other words, nearly in the ratio of the intelligence. The following are the conclusions which the author draws from his inquiries:—

1st, As it follows, from all the researches of modern science, that in man the extent and variety of intelligence are generally in proportion to the anatomical quantity of the cerebral mass, and that this determination becomes rigorous when to the quantity the physiological condition of quality is super-

added; so also in animals do the extent and variety of their instincts appear to be in relation with the quantity of the cerebral substance in each of them, the question of quality between individuals of the same species still considered. 2d, The sum of the instincts in animals compared with one another is by so much the greater as the proportional weight of the cerebral hemispheres, and perhaps also of the cerebellum, is more considerable in relation to that of the nervous centres of the cerebro-spinal axis. 3d, Life being nothing more than a harmony between accordance and antagonism, in other words, a perpetual struggle of organisms with physical agencies the nervous system, the material agent of life, performs three kinds of functions—the first, spontaneous, or proper to the living being, and which cannot proceed solely from the agency of the general laws of nature; the second, physical, and the third, chemical; these being severally shaded one into another by means of mixed intermediate functions. The spontaneous functions indicate the destination of the living being, the others form relations for the support of the material body in harmony with the laws of chemistry and general physics.

These conditions stated, M. Bourgery infers, with reference to the question of relative quantity in the nervous substance: 1st, that a cerebral nervous mass four times the size of all the rest of the cerebro-spinal organs is required for the psychological manifestations of man. 2d, The instincts of animals do not require more nervous substance than a quantity five or six times less than that which is proper to these higher manifestations. The quantity of nervous substance necessary to the organs for their several functions diminishes gradually in the following order:—

- (a.) The senses and the nerves of general sensibility.
- (b.) The physical function of motion.
- (c.) The physico-chemical function of respiration.
- (d.) The chemical function of digestion.
- (e.) The chemical function of the organic elaborations. And
- (f.) That of assimilation.—*Academie des Sciences*, Sept. 23d.

FUNCTION OF THE SKIN.

* [That is to say, 46·667 oz. avoirdupois, a weight which approaches the mean weight of the adult male English brain between twenty and thirty years of age, which, according to Dr. Boyd, it is 46·178 ounces avoirdupois, but this is without the spinal marrow, which is included in M. Bourgery's estimate.—*Vide* Dr. Boyd's Table, end of Wagner's Physiology, by Willis.—ED. GAZ.]

M. FOURCAULT, whose interesting and novel observations on this subject are generally known, has been pursuing his inquiries still further, and noting more of the phenomena that accompany the suppression of the cutaneous exhalation. He finds, for instance, that it is easy to produce albuminaria in

many animals, both by covering the surface of the uninjured skin with an impervious glaze, and by the somewhat barbarous procedure of stripping the creature of its skin entirely. Strange to say, albuminous urine was secreted more certainly in the latter circumstances, if the raw and bleeding surface of the body were covered with an impervious varnish, than if it were left naked.

M. Fourcault's explanation of the appearance of the albumen in the urine, when the skin is covered with an impervious varnish, is connected with a retention of lactic acid in the blood: "In examining successively the effects of the elements of the cutaneous transpiration upon albumen," says M. F. "it was easy to perceive that the lactic acid which comes to be in excess in the blood, when the acid excretion of the skin is interrupted, is the true cause of this phenomenon, and of the other chronic alterations of the albumen; among which are found hydro-albuminaria, scrofula, tubercle, hide-binding among infants, elephantiasis, lepra, phlegmasia alba dolens, &c."

His conclusions are these:—

1st. The skin is a purely excreting organ, and the products of the perspiration are not formed in its tissue.

2nd. When a living animal is flayed, its internal temperature remains long unaffected; albuminaria is not the result of this operation; when it occurs, it may disappear without the circumstances changing.

3rd. The artificial suppression of the cutaneous exhalation determines five orders of phenomena: *a*, a great change in the blood; *b*, a great fall in temperature; *c*, supersecretions and effusions of different natures; *d*, local lesions and vascular engorgements; *e*, alterations in the urine; among the number, albuminaria, which may also be determined, though this happens much more rarely, of a primary affection of the kidneys.

4th. The introduction of lactate of soda into the veins produces albuminaria, by favouring the formation of an excess of lactic acid in the blood.

5th. When the acid secretion of the skin is suddenly suppressed, a profound alteration of the organic elements of the blood is determined. Such an alteration is observed in the Asiatic cholera, in plague, yellow fever, and some severe diseases of these countries.

6th. When the secretion is slowly or gradually suppressed, a number of chronic diseases are produced; amongst which, we reckon albuminaria, and the other alterations of the albumen already indicated.—*Comptes Rendus*, &c., No. 19, 1844.

[We presume that the facts are all as M. Fourcault states them. His theoretical views must of course be distinguished from them; or, what should become of these

really valuable additions to our science, should it be found that the lactic acid which Berzelius invoked as a constituent of all the animal fluids, should be found to be a dream, as we are lately assured it is with regard to the urine?—*ED. GAZ.*]

CASE OF FUNGUS FROM THE SYNOVIAL CAPSULE OF THE KNEE

TREATED BY COMPRESSION.

THE subject of this case is a young man, aged thirty, of a lymphatic and deteriorated constitution. On the internal surface of the knee there is an ulcer of the size of the palm of the hand, from whose base has sprung an ill-conditioned fungus of the size of half an orange, and which, according to M. Gerdy, originates from the external surface of the synovial capsule, and has no communication with the joint. The articular movements are quite free, and cause no discharge of pus, as would be the case if the disease communicated with the synovial cavity. In M. Gerdy's opinion this is the best test that can be employed for the purpose of ascertaining if a tumor containing fluid, and which has been opened, communicates with the neighbouring articulation or not. The patient has an affection of the same nature on the dorsal surface of the wrist. The fungus neither appears cancerous, nor has any tendency to bleed: at the knee, as well as at the wrist, it is composed of an enormous number of granulations, of the size of a nut, having a greyish colour, and of a soft dirty aspect, and yielding a large quantity of foetid pus. The means employed by M. Gerdy for the treatment of this affection are, compression by means of strips of adhesive plaster, and under the influence of these, and rest, the disease is improving. M. Gerdy has met with one other case of this rare disease; it was situate at the elbow joint, and occurred in an individual in whom he had amputated the leg, but who refused to submit to the loss of his arm; it was treated by compression, and a cure followed, but there was ankylosis of the joint.

In a pathological point of view this is a rare affection; indeed, it is the first time we have met with it. An attentive examination of the joint leads to the idea that there is hypertrophy of the whole synovial capsule, with tendency to fungus from its external surface. It appears to us that the affection may be compared to certain non-cancerous fungi which occur on the mucous membrane of the alveolar processes, and which have been denominated *epuli*. Its co-existence at the knee and wrist at one and the same time, and the deteriorated state of the con-

stitution, would lead us to suspect that it originates from some peculiar diathesis. There are, however, no distinct signs of scrofula, although the patient has a pale, cachectic look; but this appearance is, perhaps, an effect of the local disease itself. However this may be, M. Gerdy has commenced the treatment by compression, to which he proposes to add the internal use of the iodide of potassium. A marked diminution in the size of the vegetations has already taken place, under the use of the compression alone.—*Annales de Thérapeutique*; and *Dublin Journal of Medical Science*.

SUPERFECUNDATION ?

A sow which had already farrowed five young ones, made a second accouchement of five more a fortnight afterwards. The second litter were small but lively. The sow, which had had several litters before, generally produced from ten to twelve at a birth.—LEHWESS, Veterinarian, in *Medicinische Zeitung*, No. 11.

LECTURES
ON THE
NATURE AND TREATMENT OF
DEFORMITIES,

*Delivered at the Brompton Square
Institution.*

By R. W. TAMPLIN, F.R.C.S.E.

Surgeon to the Institution.

Division of the vastus externus and fascia lata for knock-knee. Relaxed condition of the ligaments of the knee-joint, admitting of undue motion antero-posteriorly: treatment of. Contraction of the knee commonly called ankylosis—congenital, non-congenital. Causes of non-congenital acting directly: injuries of various kinds; inflammation simply; rheumatism; scrofulous disease, or “white swelling,” with abscesses about the joint: treatment of. Indirect causes: injuries to the spine—cerebral or spinal irritation.

In my last lecture I omitted to mention to you the mode of dividing the vastus externus and fascia lata, which is frequently necessary in the severe forms of knock-knee. After having divided the tendon of the biceps flexor femoris, let the assistant continue the forcible extension: you then examine the fascia lata just above the external condyle of the femur; if it is tense, pass a sharp-pointed knife beneath it and the vastus externus, from behind forwards, and divide it from within outwards. It is a simple operation, and one free from any casualty, as you have nothing but the bone on the inside. After the division, proceed as I described to you with the after-treatment.

To-day we shall consider, 1st, a condition of the knee-joint occasionally met with, which consists in a general elongation of the ligaments connecting the joint, and admitting of an undue amount of motion antero-posteriorly, which allows of a greater amount of

extension, without any permanent deformity or malposition, the malposition taking place only during the time the patient is taking exercise. It consists, then, in a relaxation of the crucial ligaments, combined with a generally diminished tone of the muscles, as well as of the body generally, allowing the head of the tibia on its anterior surface to approximate to the anterior surface of the condyles of the femur, the posterior surface being separated to a greater extent than is natural, whereby the thigh and leg appear curved posteriorly, and the popliteal space lost, and appearing convex instead of concave. This affection is generally met with in children of delicate constitution, sometimes combined with paralysis and antero-posterior curvature of the spine, which has been occasioned by ulceration of the bodies of the vertebrae; and patients affected in this way possess no steady method of walking, for as soon as the body is carried beyond its perpendicular position with the leg which is supporting the body, whilst its fellow is carried forwards, a sudden yielding and jerk take place, owing to the relaxed condition of the ligaments, as far as the ligaments admit of, and the muscles for the moment have no firm attachment, so that the patient appears to sink in a measure on each step taken. This produces a great sense of weakness and difficulty in walking, with inability to take much exercise without suffering from fatigue; and the very circumstance of walking occasions an increase of the deformity, in consequence of the continued stretching kept up in the ligaments. Of course your treatment will be directed to such means as will improve the general health of the patient, together with the best and most uniform support to the knee-joints; as it is only by keeping the knee-joints fixed, or, at all events, so confined that any undue motion is effectually prevented, that you can by possibility effect a cure, as if this play in the ligaments is allowed, they cannot be expected to contract upon themselves, and to limit the motions

of the joint to its natural standard, no matter how much the health of the patient may be improved.

The means I have adopted, with those unable to go to the expense of irons, is a straight splint, well padded, behind the leg, either retained in its position with strapping or bandage. This compels the patient to walk with a stiff knee for a time, but will nevertheless effectually overcome the deformity if persevered in. In others more fortunately circumstanced, I have ordered irons having a stop-joint at the knee, which enables them either to use the joint or not as they may feel inclined, with a screw pad pressing on the anterior surface of the femur, just above the knee; with a similar one behind the calf, just below the knee. These pads you will be enabled so to adapt that no motion can take place beyond the extent wished for; the knee itself being firmly held by a double knee-cap. I certainly prefer that the knee should be kept stiff whilst the patients are taking exercise, as the less amount of continued motion the better, in my opinion, although that motion may not be in itself excessive. The patients can then, if they wish it, press the bolt backward which retains the iron in the straight line, and flex the joint whilst in a sitting posture.

The time occupied in treating a case of this kind will vary according to the general health of the patient, and the success attending your efforts made to prevent any undue motion of the joint, which must be most unremittingly persevered in until the patient is enabled to walk, unassisted by support, without the yielding taking place; and even then I would not advise the entire absence of the support. It is much better to commence in this way, say half an hour daily for the first few days; and if no return of the deformity occurs, or increased motion takes place, extend it to an hour; and so on, that the patient may be accustomed to forego by degrees the support; and should any relapse take place, let any increase of it be effectually and at once prevented.

We now come to one of the most important of all deformities, the most important also of the knee-joint, involving almost invariably the necessity for a patient afflicted with it walking with crutches, or a wooden leg, which is of course a severe inconvenience, independently of the deformity itself, preventing those suffering from it taking any active exercise; I allude to *contraction of the knee-joint in the flexed position*. I say in the flexed position, because, in knock-knee you have muscular contraction, as well as in the straight or extended position of the joint, as I shall hereafter mention to you; this is commonly called *ankylosis* of the knee. This deformity or *malposition* (for that is its real character), consists either of

a permanently flexed position solely, or flexed and everted combined, a semi-rotated condition of the tibia on the femur—that is, if the legs were brought into the extended position, the knees would be found to incline inwardly to a greater or less extent, and the foot and leg everted. There is also another change of the relative position of the bones frequently met with in combination, namely, a receding of the tibia upon the posterior surface of the condyles of the femur, (vide figs. 3 and 4; this last involving the necessity of an alteration of structure, or of the natural relative length of the ligaments being lost, as will be hereafter seen. It is a congenital and non-congenital deformity; but so rarely is it met with congenital, as to form the exception. In the congenital deformity you have simply a contraction of the flexors of the knee, unaccompanied with any altera-

FIG. 1.

An example of congenital contraction of the knee, taken from a patient aged 19, in whom both knees were similarly contracted. The joint, as it may be observed, retains its normal position.

tion in the healthy condition of the joint itself, but combined occasionally with one or other of the deformities of the feet mentioned. (Fig. 1). I have once met with it without any deformity of the feet; once with talipes calcaneus of both feet, both knees being contracted; twice with talipes varus of both feet, in one of which a relaxed condition of the whole of the ligaments of the tarsus existed in one foot, allowing of free motion between all the bones, and in the same case congenital luxation of the right hip. I say luxation, because the word conveys what I wish you to understand, although, upon examination, so far as the muscles and integuments admitted of, no trace of an acetabulum could be discovered. The head of the bone could be distinctly felt on the dorsum of the ilium, and was freely moveable in every direction; it evidently was perfectly exposed and free. The leg could be drawn down without any impediment being felt beyond the resistance of the muscles, which leads me to suppose there is at all events no brim of the acetabulum or cotyloid ligament. That patient suffered also from severe lateral curvature, whether congenital or not I am unprepared to say, combined with a semi-rotated or twisted position of the vertebrae, and flattening of the ribs, which presented posteriorly an acute angle; in fact, a more generally deformed condition, or more miserable object, can scarcely be imagined. In all my experience I have never met with a more distressing case. In the case in which double varus coexisted, the skin was adherent to the patella, and was indented, presenting the appearance of an old cicatrix. In the first case mentioned there was no additional deformity or malposition, simply contraction of the flexors, and perfect voluntary power of all the muscles, so far as the contraction admitted of, (vide fig. 1) the joints themselves being perfectly healthy, and the articulating surfaces in their proper relative position, that position being the flexed, but not quite to a right angle. The patient was also enabled to flex the joints to their full extent, and to extend them, as I have said, as far as the contraction admitted of, at will; there being, in these cases, no evidence of any diseased condition existing, or having existed, in the nerves or muscles. I regard this deformity also as the result of position in utero, when unattended with malformation or deficiency of formation in any of the natural structures; for I imagine it is not more difficult to conceive that the extremities of a child may be so placed, during uterine existence, that they will admit of very little motion in the extended position of the knees, than to imagine the feet being placed and kept in those positions in which we find congenital deformities of the feet.

With regard to the non-congenital, which

you will have the more generally to treat, and which are by far the most serious and difficult, the causes are numerous; and I would divide them into those which act directly, and those which act remotely, on the articulation. Of those acting directly may be mentioned, injuries of various kinds; inflammation of the synovial membranes, whether it be confined simply to the joint, or whether it be the result of rheumatic condition generally, affecting one or both of the knee-joints particularly, and resulting in contraction of the flexors; inflammation of a chronic character of the synovial membrane, arising from scrofulous disease of the joint itself, or, as is most frequently met with, in the neighbourhood of the joint, and producing chronic inflammation of the synovial membrane, from the irritation occasioned by its close proximity to the joint, oftentimes surrounding it in almost every direction, but without causing any change of structure in the joint itself, beyond the synovial membrane. Among the remote causes may be mentioned, injuries to the spine, producing pressure on the chord, and paralysis, in the first instance, of the entire lower extremities; cerebral or spinal irritation, or disease, producing partial loss of power in the extremity or extremities, sometimes complete loss of power, in which case, upon recovery from it, as in the last mentioned, contraction of the flexors is a consequence. The first mentioned, namely, injuries to the joint, consist of the various mechanical accidents to which every one is exposed, such as the joint being jammed, or those caused by any sharp or blunt instrument, the joint itself being exposed or punctured. In either case inflammation more or less severe is the consequence, during the existence of which the joint is kept in the flexed position, and upon recovery from which a permanent contraction is found to exist, with or without alteration to a greater or less extent in the synovial membrane; as I mentioned to you, when speaking of the deformities of the feet, that there is a constant effort instinctively exercised to keep the joint at rest, the slightest motion occasioning the most severe pain; and the position in which there is the least amount of pressure on the articular surfaces, and therefore on the synovial membrane, is undoubtedly the flexed position, as in the straight position, even without the additional pressure occasioned by the weight of the body, there must be a small amount of pressure between the articular surfaces; and be this ever so slight, if the synovial membrane is inflamed, it must of necessity increase the inflammation, and consequently the pain, which is, as you are aware, at all times most acute, and requires in its active stage the most prompt and vigorous measures for its relief. The flexors, therefore, are constantly acting, and become eventually

contracted, from the flexed position being maintained during the inflammatory attack; and should there be any disorganization of the joint itself, or parts composing it, you will have also more or less lateral or posterior displacement, combined with the flexed position. In those cases, of which we have had several, I have been of opinion that the synovial membrane has become altered in structure, thickened and inelastic; and there have appeared also adhesions of some kind, as in all these cases I have found the joint to possess scarcely any perceptible motion; and if any, the smallest in amount, and that motion being independent of the muscles themselves, as you will generally be enabled to discover, provided you continue your extension for some minutes, by which method the muscles will relax, and you will be enabled to form a correct opinion of the resistance existing in the joint itself; besides, in these cases, you will generally find the joint not only flexed, but immoveable in the flexed position; that is, you will be unable to flex it beyond the position you find it in, which can be invariably accomplished in cases where the joint itself retains its integrity, and as may also be seen in cases arising from paralysis, when free motion exists so far as the contraction admits of. These cases, then, arising from wounds inflicted on the joint itself, will appear, upon a superficial view, to be perfectly ankylosed, and will require the most scrupulous care in examination before you decide on their real condition.

In one case admitted into this institution, which arose from a cart-wheel passing over the thigh, just above the knee, there was motion, but of an elastic kind; and after the leg had been forcibly extended, it returned with an impulse to its contracted position, without the flexors acting in the least, so that it was evident there was some adhesion or adhesions in the joint itself. The flexors I divided, however, and the extension was kept up for some weeks with very little benefit; and from the severity of the increasing forcible extension necessary, the patient suffered so much that he left the institution, determined to submit to no more treatment. But after a few weeks he returned penitent, and engaged a lodging close to the charity, when I re-operated, and again commenced extension. We progressed, as heretofore, but very slowly, and, from his good conduct, the committee readmitted him. From the constant pressure again kept up on the anterior surface of the thigh, a slough made its appearance, upon the healing of which I resolved to make no farther attempts, and informed the patient that I feared nothing more could be done for him, and advised his procuring an instrument to hold and fix the joint in the position in which it then was. This

frightened him, and he set to work to screw his leg straight at all hazards, upon doing which a sudden and loud snap was heard, compared to the report of a pistol by the other patients, and immediately his leg could be placed in the straight position, or nearly so; since which occurrence the leg has been kept, without difficulty, very nearly straight, and he has left the charity with a comparatively useful limb. This, therefore, is a valuable and instructive case, as it justifies an amount of force being used in similar cases, after other means have failed. He suffered pain only upon motion, and has not been in any way inconvenienced beyond the temporary pain mentioned.

I also stated inflammation of the synovial membrane as a cause: I mean idiopathic inflammation of the joint, which arises without any apparent cause, and without the general health having previously suffered: in this case, if the disease is not stopped at its onset, effusion into the synovial cavity is the result, and, of course, a change, whether permanent or not, in the synovial membrane, is a consequence (Figs. 2 and 3). In simple inflammation, however, the results are not so severe, if properly attended to, as in inflammation arising from injuries, or from a rheumatic state of the constitution, when it assumes more of a specific character, and is oftentimes more obstinate, yielding but slowly to treatment. But whether simple or not the effects are the same, if the position of the limb is unattended to, namely, contraction of the flexors of the joint, which contraction becomes permanent, whether there is or is not any evident change in the secretory surface of the synovial membrane. In rheumatic inflammation, as I mentioned, a change of a serious character frequently results, producing adhesions, which, if allowed to remain passive, terminate in complete ankylosis. Several cases have presented themselves in whom not the slightest motion could be detected by the exercise of great force, and that after a few years' duration. In fact, cases have occurred where three years only had elapsed and this condition of the joint existed, rendering any attempt at cure futile. Of course there are exceptions to this; and if motion is found to exist, and all evidence of diseased action gone, you will at all events use every effort to restore the position of the limb and the functions of the joint. This cause is therefore as serious, if not more so, than any we have considered or shall have to mention, and will require the greatest attention and perseverance in the treatment.

We come now to another cause mentioned, namely, scrofulous disease of the joint, or in the neighbourhood of the joint. This is, as you are all aware, a very common cause, and one which frequently results in the loss of the limb by amputation; and I would beg to

FIG. 2.

An example of contraction of the knee from inflammation, in which the displacement, viz. partial dislocation of the tibia backwards, is most apparent. Taken from a female, aged 19 years (vide also fig. 4).

FIG. 3.

The same after treatment. The position of the bones was perfectly restored by means hereafter to be mentioned.

draw your attention to what I consider to be the actual condition of the joint and the character of this disease. My remarks must apply to children and young subjects, as, of course, in the adult this disease does not present the same uniform character, nor have adult patients that innate restorative power which is so active during early life. Now I regard this affection as one of the ordinary processes attending a departure from the healthy state, whether it attacks the bones surrounding the joint, the synovial membrane, or the cartilages and ligaments themselves, and not as a disease of a malignant character, admitting of no known remedy, and which terminates ultimately in the loss of the part affected, and oftentimes in the loss of life. Now, what are the physiological

conditions of the parts entering into the composition of a joint? It is composed of bone, ligaments, and a delicate semi-transparent membrane, called the synovial membrane. The bone is the foundation, if I may so speak; the cartilage is so arranged that it gives an elasticity and smoothness, and in this way facilitates motion, whilst the synovia secreted by its membrane lubricates the surfaces; and by these means the motions of the joints are rendered perfectly free and uninterrupted, the articulating surfaces gliding insensibly over each other. The bone and cartilage exist in a comparatively low state of vitality, and do not possess the power of resisting the effects of disease, at least only in a comparatively diminished degree, whilst the synovial membrane readily

becomes the subject of disease, and, when it does so, the disease is generally of an acute character, which, in a short space of time, alters its secretion, and if the inflammation proceeds, the membrane itself becomes altered in character, and, instead of facilitating the movements of a joint, becomes in fact a direct obstacle, and, according to the amount of change in structure, limits or entirely prevents the natural motion taking place. From the fact of bone and cartilage possessing a *low state of vitality*, and being incapable of resisting to any extent, the effects of diseased action, after positive disease has existed and subsided, the restorative process is, as might be easily anticipated, exceedingly slow, under the most favourable circumstances, and if the cartilage has been destroyed, it does not effect a reproduction, but is supplied by a sort of ivory substance, polished and hardened, supposing the diseased action stops at the cartilage. The synovial membrane also, if a great change has taken place, does not reassume its thin, elastic, semi-transparent character, but remains more or less thickened, and its secretion is either altogether lost or altered

in quantity and character, and although motion is admitted of, yet it is not that free unlimited motion which the joint possesses in its healthy condition. In the knee-joint you have also the crucial ligaments surrounded by the synovial membrane, and forming the most important connection of this articulation. If, then, inflammation takes place in the joint to any extent, of course the ligaments must suffer more or less, becoming softened and unable to fulfil the office for which they exist, namely, retaining in position the articulating surfaces of the condyles of the femur and head of the tibia. Now, by becoming softened or weakened, of course the muscles would tend to occasion a displacement of these bones to a greater or less extent, independently of the contracted or flexed position, as if the bones were not firmly held in apposition. The head of the tibia will be drawn out of its natural position by the constant action of the muscles, in the direction in which there is a preponderance of power, and this direction is both backwards (vide Fig. 2), and lateral, or both combined, (Fig. 4) occasionally also with more or less rotation of

FIG. 4.

A diagram of a preparation in the museum of St. Bartholomew's Hospital, for which I am indebted to the kindness of Mr. Lawrence, illustrating the almost complete dislocation backwards of the tibia upon the femur, arising from inflammation of the joint and subsequent contraction. A, *External lateral ligament*, which may be observed to be almost horizontal; B, *Ligamentum patellæ*; D, *Tibia*; E, *Fibula*; C, *Femur*.

the tibia, — (Fig. 5) the lateral deviation being, to the outside, from the great power exercised by the biceps, flexor femoris, as this muscle is not only very powerful, but

passes more on the outside than the semi-membranous and semitendinous do in the inside in their course to their insertion; these two last mentioned lying more behind

FIG. 5.

An example of contraction of the knee, combined with abduction, and slight rotation outwards of the tibia, as may be observed arising from the scrofulous disease about the joint. Taken from a patient now in the Charity.

the joint until they wind round the head of the tibia. It is in this way only that I can explain the abduction of the leg, of which we shall presently speak. The restorative process is, as I have just stated, of necessity an exceedingly slow and tedious one, under the most favourable circumstances; whether the disease attacks the joint itself or the extremities of the bones surrounding it primarily, the joint secondarily. It requires the joint to be kept at rest, or nearly so, and a uniform support to the entire limb; the natural temperature maintained, and the general health supported, and this most uninterruptedly followed up. By these means I believe that most diseases of the joints, in young subjects, provided they are not malignant, which I do not believe they can be considered, may be cured, and even if the patients have suffered from destruction of the joints and of the bones, or that portion forming the articulating surfaces, although all motion may be out of the question, yet I distinctly maintain that an ankylosed knee, with the use of the foot, is far preferable to a wooden leg; and the most favorable position may be selected during the period the restorative process is going on. In the majority of cases of strumous disease, the joint itself is but slightly affected, although the surrounding parts are one mass of disease.

The inflammation consequent on the irritation of that disease is of a very chronic character, and does not appear in those cases to risk the integrity of the joint, although there may be, and generally is, an increased secretion of synovia, but beyond this the joint does not appear to suffer; at least, in an immense number of cases. I have witnessed the most frightful amount of disease, appearing in a superficial view to exist in the joint itself, and yet the joint remain perfectly sound, with the exception of the increased quantity of synovia.

I have now a case under treatment in which the joint presented the appearance of a fungous mass, with openings in every direction—enormously swollen. The anterior surface of the patella, the femur immediately above the condyles, the tibia immediately below the articular surfaces, were all diseased, and yet the joint itself was free, except, as mentioned, the quantity of synovia increased; yet this case, the most frightful that can be imagined, is yielding to treatment, and the general health of the patient is restored.

A case occurred to me three or four years since, of which the following was the condition of the patient: the girl, about 8 years of age, was sitting on the bed in the most miserably emaciated condition, and was stated to have been suffering from disease in

the knee between two and three years. There were five openings, two on the outside, just above the condyles, one on the inside, and two on the patella. The three first communicated with the femur, the two last with the patella. The parents stated at least half a pint of matter was discharged daily. Of course, this was somewhat exaggerated, but an immense discharge was then evident, of that peculiar, thin, unhealthy secretion, common in scrofulous diseases. The knee was contracted beyond a right angle, so that you could not pass a thin piece of sponge between the leg and thigh, in the situation of the popliteal space. The knee itself was swollen and distended with fluid. She was suffering from acute hectic fever, with profuse perspiration and severe pain on the slightest motion. The pulse was fluttering, the bowels relaxed; in fact the child presented the appearance of a person in the last stage of consumption. I ordered her an opiate, with the *hyd. c. cretâ* every night, the *conf. aromat.* and *ext. cinch.* 3 or 4 times a day, a soft linseed-meal poultice, made by stirring the meal into boiling water, over the whole of the knee-joint, covered with oiled silk. A tin splint, bent at the angle at which the knee was flexed, with pads, and retained by means of a flannel bandage, from the toes upwards above the knee, thereby keeping up the natural temperature of the entire limb, as well as a uniform gentle support; together with a nourishing diet, consisting of eggs, milk, meat, beer, and then two glasses of port wine daily, commencing the stimulants by degrees. In a few days, the general irritability subsided, and the pain in the knee was relieved, the hectic left her, and the discharge altered its character. In fourteen days she could be moved without a complaint.

This treatment was continued six months, varying the tonic, at the end of which time all the openings were closed, and the swelling of the joint almost gone. The leg was extended in the most insensible manner, by gradually straightening the splint during the period the disease was subsiding, and without pain being produced. As soon as the openings were healed, I supported the joint with *emp. cerat. saponis*, and continued the bandage and splint, and in twelve months the leg was brought into the straight position, and the girl could use it without any assistance. I then directed the joint to be exercised daily, by forcibly flexing and extending it, as far as the feelings of the child would admit, and in this way the motion of the joint was restored, the muscles of the thigh and calf developed themselves, and a perfectly useful limb is the result. In this case amputation was advised by several surgeons as the only means of saving the child's life.

I would beg to mention another case similar in some respects, of a boy 9 years of age, in whom what is called white swelling had existed for eighteen months. There were no openings, but a bag of matter situated in the upper and outer side of the femur just above the condyles. The joint also distended with fluid, and contracted beyond a right angle. The same treatment was followed here: the matter gradually and entirely disappeared, the swelling of the joint reduced, and by means of the splint, the leg was brought, in eight months, into the straight position, and the boy enabled to use his leg, supported with a straight splint. In this case also amputation was recommended, and would certainly have been carried into effect had the boy assented. I have used the poultice made in the manner described, as it acts both as a fomentation, and enables you also to apply slight support to the distended and weakened capillaries, over the whole surface. The splint keeps the joint steady and relieves the pain, at the same time that a permanent contraction is prevented by the gradual and steady extension kept up, and the flannel bandage maintains the temperature and gives a uniform support; for it is certain that no restorative process can go on if the natural temperature is reduced, which you will frequently find to be the case in these subjects. The opium greatly allays the general irritation from which they suffer so severely in consequence of continued pain, and is, according to my experience, of the greatest possible advantage.

I have ventured on this digression, because I believe that many legs are lost simply from want of attention to what are often considered trifling details, but which trifling details form, in my opinion, the most important portion of the treatment. By their use I believe that the majority of cases may be saved from the dreadful alternative of the loss of the limb, which, to the poor, whose living must depend on their daily labour, is of infinite importance, far more so than to those whose means place them beyond the necessity for exertion. It has been said that such cases are daily occurring, and occurring in every one's practice. Admitted; but does not this prove that the opinions expressed are incorrect, and if these and others have had the use of their limb restored, there are, in all probability, hundreds who have suffered amputation that might have possessed a useful member? It is an easy matter to take off a leg, but the consequences to the patient exist for life. How often is it said, in similar cases, "we must first get the patient into better health, and then perform amputation." Now I want to know how a patient suffering from this disease in its most severe form can, during the exist-

ence of that disease, and in spite of it, be brought into better health, into such a state of health as will admit of his bearing the operation, and yet the health should not continue to improve, and with proper attention the disease should not be cured also. It is certain, if the severe symptoms I have mentioned be allowed to continue, death must be the result; but until you can prove to me that the disease is, from its nature, incurable (I mean of course in young subjects), I am not prepared to admit either the necessity of amputation, nor that the disease will continue and destroy life, unless that extreme measure is resorted to. Again, supposing the bones themselves diseased, and the integrity of the joint destroyed, what is to prevent the restorative process from going on, and a comparatively useful limb being secured to the patient? We have evidence in abundance of this being effected in the instances of ankylosed joints that present themselves almost daily, of the hip, knee, and elbow. The misfortune is, and what I would particularly draw attention to, that from the comparatively low organized condition of the structure of the joint, the efforts of restoration are proportionally slow, and occupy many months of treatment and, of course, of attention: but what is this compared with the life of the individual, and his being enabled to obtain his subsistence in any capacity he may be placed; whereas, with a wooden leg, no very active employment can be undertaken, for, independently of the appearances it presents, objections naturally arise to the employment of such individuals. My object in making these remarks is solely to attract attention to what appears to me a very much neglected disease, and I believe, in many instances, this arises from an impression that it is a disease, if not incurable, at least so far hopeless that it is useless to waste the health or time of the patients in any attempts at cure. If in these remarks I shall be the means of drawing attention to the subject, and in this way of saving the limbs of patients thus afflicted, whatever may be the opinion entertained, I shall have obtained more than I have any reason in right to expect. The assertion of these views is a bold step, and I am well aware that my motives may and will be questioned, and my opinions disputed. I have, however, a duty to perform in common with all men, and I trust never to be deterred by fear from openly and decidedly stating my opinions, believing conscientiously that they are correct, and believing also that general good may result from them.

In reasoning upon the cases mentioned, as well as upon numerous others which have been left for amputation, but which some fortunate accident has prevented; reasoning,

I repeat, on these condemned limbs, which have ultimately been restored, I feel myself fully justified in suspecting that there are many limbs similarly affected which might, by similar means, be restored, but which are now unhesitatingly doomed to the knife.

The next cause mentioned is one remote from the joint, namely, injuries to the spine, producing, in the first instance, paralysis, upon recovery from which, contraction of the flexors is the result, oftentimes combined with contraction of the gastrocnemius also. In these cases you have, of course, no change in the joint itself, except the change into a permanence of the flexed position, neither is there any alteration in the relative position of the bones. The patients who meet with these severe accidents are confined for a long period to their beds, and after the spinal column has been relieved from the pressure occasioned either by the bone or the effusion of blood or serum, as the muscles recover their lost power, the most powerful, which are the flexors, overcome their weaker antagonists, and a gradual contraction is the result, so that when the patient is allowed to leave the bed, he finds himself unable to straighten his legs, and, if the gastrocnemius is contracted, of placing his feet flat on the ground, the contraction taking place previously to the patient being enabled to exercise any voluntary power. We have had two cases of this description in the charity; the one a man, of whom this is a cast, the other a boy. The man was a bricklayer's labourer, and fell from a scaffold, either fracturing or injuring the spinal column at the lumbar vertebrae; perfect paralysis followed, upon recovery from which contraction of both the knees was the result. The tendons were divided, and the limbs restored to their straight position, and as there was no paralysis of the extensors, free voluntary power followed, and the man left the charity well. The boy was a sailor, and had fallen from the mast of a ship: the same result followed, with the addition, in this case, of contraction of both the gastrocnemii. There was no remaining paralysis in this case, and the boy left the institution walking with tolerable comfort.

In the cases that arise from cerebral disease, or irritation, you will generally find paralysis of the extensors, and contraction, in one or other of the forms mentioned, in the feet, but in these instances, as well as in those just mentioned, no disease or obstacle to the joint itself. There is, however, occasionally some displacement of the articular surface, which, I imagine, arises from the general loss of tone affecting the ligaments, and allowing of their relaxation, when, of course, the tibia becomes displaced, generally outwardly, producing, when the leg is extended, a knock knee.

With this, gentlemen, I conclude the causes; in my next lecture I shall proceed to the treatment. I must, however, apologise for having digressed on the scrofulous diseases of the joint.

ON THE PRESENT STATE OF THERAPEUTICAL INQUIRY.

BY JAMES ARNOTT, M.D.

Physician to the Brighton Dispensary.

[Continued from page 412.]

(For the *London Medical Gazette*.)

THE principal sources of the acknowledged remedies of disease are:—

First, The *observation* of the effects of accidental occurrences or influences on the sick; of the effects of substances or remedial measures used empirically; and of the obvious remedial operations of nature and her instinctive dictates in disease. Secondly, the *analogy* observed to exist, either between diseases, leading to the employment of the same or a similar remedy in each; or between remedies, leading to the advantageous substitution of one for the other. And thirdly, the demand arising from the obvious nature of many diseases for the direct application of remedies acting on purely mechanical or chemical principles. The treatment of fractures, dislocations, herniæ, obstructions of canals, the extraction of foreign bodies, the extraction and change of the properties of poisons by antidotes, the stoppage of hæmorrhage, &c., are examples of remedies proceeding from this source. The appropriate remedies for these diseases are not only suggested by mechanical and chemical science, but such remedies have in many instances been brought to a high degree of perfection by the advancement of these sciences.

The opinion has been very generally entertained, that it is to the deductions from medical theory that we are principally indebted for our most efficient remedies; and it is mostly for the advance of medical theory, that the physiologist and the other zealous students of the collateral sciences above alluded to, prosecute their labours. It may be very true, as already stated, that these labours will be eventually successful in attaining their object; but the history of the medical art would forbid us to expect a very

speedy accomplishment of this; for very few useful practices in disease can be fairly attributed to the deductions of medical theory in the usual sense of the term. Plausible theories have indeed been given in explanation of the action of most of our acknowledged remedies; but it must be well observed, that these have been invented subsequently to, and not before the discovery of the remedy. A remedy, indeed, may be accidentally discovered from its trial having been suggested by an erroneous theory; but if theories are to be allowed the character of utility on this account, it would follow that they would be useful in proportion to their error or absurdity; for they would then be less likely to keep long possession, and by their rapid succession, give greater scope for new trials of medicines. The greater part of our valuable remedies were discovered before physiology was sufficiently advanced to admit of the possibility of correct theory. The circulation of the blood was discovered only two centuries ago.

It is not therefore to medical theory, or the branches of science on which it is built, that we are to look for the speedy advance of therapeutics from the very low condition in which, as we have seen, it still exists, but to the adoption of proper modes of making the above real sources of discovery most available. It may be, with this view, useful to refer to a few examples of discoveries or improvements in medicine proceeding from these sources. In doing so, it will be convenient, and conducive to brevity, to consider in each example the original observations or applications of a remedy, and a subsequent extension of the discovery by analogy.

The great discovery of vaccination (if prophylactics may be classed with remedies) as a perfect security in the vast majority of instances against the contagion of small-pox, originated in the accident of some peasants occupied in milking cows having become affected with cow-pox; and as the discovery of its protective power was really made by the milkers themselves, it is unlikely that a very acute sense of observation was required for it. But it demanded talent and perseverance of the first order, which were found in Jenner, to establish the discovery in

opposition to the prejudices which theory raised against it; for theory in this instance, as in numberless others, instead of promoting, retarded the discovery of truth.

The principle of vaccination has not as yet been extended to other diseases of similar character; and it is extraordinary, considering the importance of the investigation, that the attempts to do so have been so few and so imperfect. The Gloucestershire milkers had observed that, while small-pox was raging where they lived, those amongst them who happened to be affected with cow-pox, or who had lately been so, were safe from the contagion of small-pox. May not the singular immunity which some persons appear to possess from other diseases of the same class arise from their having had their constitutions guarded by analogous means which by patient and extensive inquiry might be ascertained? Would it not be most extraordinary that small-pox should be the only disease which, in a malignant form at least, can be prevented by inoculation either with virus of the same disease, or a modification of this virus, or by the constitution having been previously affected with a totally different disease? Might not a person who appears to enjoy immunity from scarlatina, for instance, have been affected with it under peculiar (and ascertainable) circumstances, so that its existence may have passed unobserved? Could the virus of this terrible disease be modified, as that of small-pox has been, by infecting some species of animal with it? Would mixture with other substances effect a similar change in the virus? Could the human constitution be so temporarily changed by the action of medicine or other causes of this description, previously to exposure to contagion, as that the same beneficial result should follow? It is to be regretted that instead of trying the various new remedies for scarlatina, each ushered before the public with the praise of infallibility, and each found to be as worthless as its predecessor, a thorough investigation should not be made into the means of preventing its occurrence, or at least of assuaging its virulence.

These remarks on scarlatina lead me to the subject of the accidental discovery of a remedy for a disease closely allied to it, and which fell under my

own observation several years ago, while residing at St. Helena. There prevailed at the time an endemic and supposed contagious species of malignant sore throat (diphtherite?) which had, in the majority of instances, resisted all the remedies usually employed in such affections. The wife of a serjeant in the garrison had four of her children labouring under this affection, at the same time that she herself was suffering from some illness for which the surgeon in attendance had in his morning visit prescribed an emetic mixture. It consisted of a strong solution of Tartrate of Antimony, a certain quantity of which was to be taken at intervals until vomiting should be excited. The poor woman, supposing that this mixture had been sent for one of her children, the last attacked with sore throat, not only administered it in the large doses intended for herself, but continued to exhibit it during the day so as to keep up a frequent and severe vomiting. I accompanied her medical attendant in his evening visit, when we found this child in a state of extreme exhaustion, but in all other respects much relieved. It rapidly recovered; and the practice of severe and continued vomiting was adopted during my stay on the island in many subsequent cases of the same disease, with equal success. The same method of treatment has, since the above occurrence, and perfectly independently of it, been resorted to in cases of croup by several practitioners who have recorded their success in the medical journals. In his recently published and excellent lectures, Dr. Watson speaks of it, in conjunction with bleeding, as preferable to any of the usual practices in this disease; and Dr. Cheyne strongly recommended similar treatment (to which he states he had also been led by accident) for what he terms the second stage of croup. I have learned also that severe and continued vomiting was employed by the medical officers of our army in Egypt to arrest the rapidly disorganizing ophthalmia which then prevailed; and it is manifestly applicable to other diseases of the same character, requiring the adoption of prompt and decided measures.

If, as has been asserted, many of the injurious medical practices, which obtain amongst the lower uneducated classes, like the heating regimen in

eruptive fevers, had their origin in erroneous theory, it can, on the other hand, scarcely be doubted that their useful practices originated in accident, and because they were not opposed by erroneous theory. Their mode of treating burns by keeping the affected part near the fire is supposed to have led to Dr. Kentish's plan. But another popular remedy for burns, which was lately mentioned to me, might, had it been duly appreciated, have led at a much earlier period to a great improvement in surgery. A lady related to me that when a girl, and while residing at a farm-house in Kent, her face and neck were by some accident severely scalded. As there was no assistance to be had from any medical practitioner without great delay, her relatives consented to the application of a popular remedy in that part of the country, consisting of a thick plaster of mud taken from some adjoining lane or pool, with which the whole injured surface was covered, and which was retained upon it for several days. When the mud was removed it resembled in its dry state, according to my informant's description, the plaster mask of a bust. The scalded surface rapidly healed under this treatment, and only a slight scar was left on the forehead. Now it is obvious, that this method differed in no material respect from the practice which has been adopted of late years in burns, of covering the injured part with a thick layer of flour, cotton, soap, basilicon, or some other similar substance; each of which has been introduced as a great improvement on preceding plans, but all of which obviously operate upon the same principles, and chiefly, no doubt, by protecting the injured parts from contact with the air.

There are few proceedings in surgery which afford a better illustration of the extension of the preventive or remedy of a disease to analogous diseases, than that of protecting morbid parts from the air.

That the air acts injuriously on diseased surfaces had long been suspected by surgeons; the wonder is that so much time should have been allowed to elapse without settling the question. The ridicule which was thrown on this idea by Mr. John Bell was well calculated to divert the attention of surgeons from the inquiry; and this ridicule might have been more success-

ful had not Bell's doctrines on the subject been opposed by the more authoritative assertions of Abernethy. The expediency of opening lumbar abscess in the manner the latter surgeon recommended, in order to exclude the air, was generally acknowledged, although the danger may in this particular instance have been exaggerated; for it would not be an easy matter for air to penetrate through a narrow and deep channel into the cavity of an abscess, the pliable sides of which are exposed to the pressure of the circumambient atmosphere. The effect of plasters and other dressings to ulcers was a more obvious proof; or the benefit proceeding from the common unctuous applications to burns.

The subcutaneous incision of the tendons in contracted and distorted limbs, an operation which is assuredly one of the greatest modern additions to surgery, has recently sprung from an extension of this principle of excluding the air; and improvement from the same source is probably not yet at an end. There is error surely in so frequently exposing wounds and ulcers to the air, as is generally done by the unnecessary removal of dressings; and these in many cases might be advantageously removed and reapplied while the morbid part is kept immersed in warm water; or the discharge from an ulcerated part may be permitted to escape through a valvular opening in some membrane impervious to air which has been spread over it. If air acts injuriously on healthy surfaces, as has been supposed by many (a question which a few simple experiments would determine) its contact might be prevented during great surgical operations by performing them in a chamber of the form of a large bell, in which the atmospheric air has been replaced by a gas of innocuous quality, the operator and patient being supplied with air for breathing from without. And even granting that atmospheric air does not injure healthy surfaces, it may prove injurious when once admitted into cavities, by remaining in contact with them after the surfaces of these cavities have become diseased.

In a recent number of the *MEDICAL GAZETTE*, I have, in the course of some observations on a case of empyema, suggested two modes of preventing the entrance of air into the cavity of the

pleura in paracentesis, by the adoption of either of which, it may be hoped, the principal danger hitherto attending that operation will be removed.

Amongst the expedients that have operated beneficially in excluding the air, cauterizing the surface by nitrate of silver, a practice highly commended by Mr. Higginbottom, might have been included. But the other remedial agencies of this substance are so great, whether it be applied to the skin or mucous membranes, as to throw this particular effect of it into the shade. These agencies have only lately been duly appreciated; and their extension to the various diseases in which they are employed furnishes another striking illustration of the subject before us. A better proof that we were not led to the employment of lunar caustic in these diseases by any process of reasoning or theory, cannot be adduced, than the fact, that as yet, and after its efficacy in their cure is fully ascertained, no plausible explanation of its *modus operandi* has been afforded. It was probably, when pursuing a practice which I had a little while before introduced in strictures of the urethra, namely lateral cauterization, that M. Lallemand accidentally discovered the advantage of cauterizing the prostatic part of the urethra for the removal of irritation from the ducts entering it; and soon afterwards, and, as he alleges, with the greatest success, he applied the caustic in its solid form to the mucous coat of the bladder in obstinate cases of chronic cystitis. This powerful remedy has now been extended to every accessible part of the mucous membrane; amongst others, to the eye, fauces, vagina, and uterus. Besides its employment in diseases of the œsophagus and rectum, it has, I believe, as respects the gastro-intestinal membrane, been applied by injection to the whole of the larger intestine in cases of chronic dysentery; and even, it may be said (considering the large doses in which it is occasionally administered in the form of pill), locally to the stomach. The pulmonary mucous membrane is less accessible; but even here, in inflammation and ulceration of the upper part of the windpipe, the late Dr. Armstrong recommended its use after laryngotomy. Might it not yet be more extensively applied in disease of the bronchi and lungs? Might it

not, either by itself, or in conjunction with some lighter substance (in order that by this means and agitation it may be suspended in the air), be occasionally drawn into the lungs with the breath?

Many other interesting examples of the accidental or empirical origin of remedies might be adduced did the argument require it; and some which, though we might have been led to them by analogical reasoning, we should scarcely have dared to venture upon, had not we otherwise discovered their utility and safety. In chronic hydrocephalus and empyema, the operation of tapping has been performed accidentally, and with complete success, by a nail penetrating the skull in the first instance, and by some similar accident in the second. The accidental origin of the cure of puerperal convulsions by copious bleeding may be also deemed another example of the kind. It is unnecessary, however, to give further details on this part of the subject; nor shall I enter at all upon the consideration of the well-known cases in which nature has been our instructress; but instead of occupying the reader's attention with what must already be familiar to him, I shall proceed to give a few examples of remedies acting purely on mechanical and chemical principles.

The relief from pain which is experienced immediately on the bursting of an abscess, and which pain has evidently proceeded from the tension of the parts containing the pus, must have led at once to the surgical expedient of opening abscesses. Numberless other surgical operations are founded on the same principle of relieving distension by a division either of the distended and painful substance itself, or of what may unequally restrain the increasing size in morbid parts, and thus probably, by unequal pressure, cause stretching, and pain in some portion of their structure; for pain usually proceeds from the unnatural tension of the nerves pervading the distended tissues. Amongst these surgical operations may be enumerated the division of deep-seated aponeuroses in abscess of the extremities; of the tendinous fascia in whitlow; and of the similar structure in deep-seated abscess, or inflammation over the cranium. Scari-

fication of the gums in teething, of the conjunctiva in ophthalmia and chemosis, and in phlegmonous erysipelas, are remedies of the same class; although in all, the loss of blood that accompanies the operation likewise operates beneficially in the cure. The mode of treating phlegmonous erysipelas by scarification would appear, from an account which I received from an officer of the St. Helena garrison who had been a prisoner there after our unfortunate expedition to Buenos Ayres, to have been a popular remedy in South America before its adoption in Europe. Much of the pain accompanying inflammation may proceed from the distension of the blood-vessels themselves, and so much of it may, perhaps, be directly relieved by this incision.

Although these several operations, or modes of treatment, are so closely allied in principle, this principle has not been generally recognised; and several of them, after long intervals, have been introduced as remedies of a completely novel character. Whether the principle can be farther extended, as to the relief of severe pain in orchitis, and that accompanying the inflammation of gout, &c., remains for future observation.

Approaching in character to this principle of relieving distending parts from a restraining pressure, is the operation of tapping, or puncturing, as practised in diseases of the head, thorax, abdomen, eye, bladder, &c. for the removal of effused serum, pus, blood, or fluids peculiar to the organs. Until lately, diseases affecting the two first-mentioned cavities were allowed to prove fatal when this operation might have restored health; and there are grounds for thinking that the principles may be yet farther extended to effusions within the head. The operation for the removal of effused fluid in this situation has been limited to where it occurs in chronic hydrocephalus, and where there is supposed sanguineous effusion between the skull and the dura mater after external violence. But why not attempt the same thing in the last stage of acute diseases attended with such effusion, and in apoplectic hæmorrhage, when other measures have manifestly proved unavailing, and death rapidly approaches? Even under circumstances where life

would otherwise cease, the circulation of the blood might be continued by artificial respiration until the pressure were removed from the brain either by extracting the effused fluid, or (which might be sufficient in many cases) by removing a portion of the calvaria, and making an opening in the membranes, or even in the unyielding cerebral substance itself*. In most cases of sudden death from apoplexy, there is probably great effusion, and the usual site of this is known. How soon the blood coagulates, and when, after this has occurred, the serum separates from the crassamentum, are points not yet ascertained. Where the slightest hope remained of advantage from other measures, or the curative operations of nature, such a proceeding would, in the present state of our knowledge, be inadmissible; but under other circumstances, as the patient by this time is generally unsusceptible of pain, there does not appear any reason for an absolute prohibition of the attempt. Wounds of the brain are not in themselves so dangerous as might *a priori* have been supposed. The frequency with which the ventricle has been successfully tapped in chronic hydrocephalus, is a proof of this; and still more conclusive is the fact, that persons have recovered after the loss of a considerable portion of the brain. The details of a remarkable case of this description, which occurred a few years ago in the neighbourhood of Brighton, have been recorded in the MEDICAL GAZETTE, for Jan. 1844. There can be little doubt that fungus cerebri (which has frequently been cut off without any bad effect) consists, in many cases, of a portion of the substance of the brain protruded through an ulcerated opening in its investing membrane in consequence of internal hæmorrhage; and to this safety valve in these cases the patient may owe his escape from the suddenly fatal effects of pressure.

This suggestion (which has not the character, assuredly, of either boldness or danger), of extending a principle already in use for relieving the brain from the pressure of an effused fluid,

* "In apoplexy, after the breathing has altogether ceased, it is obvious that life might be prolonged for several hours by artificial inflation of the lungs, but as no ultimate benefit could be derived from such an operation its expediency may fairly be questioned."—*Medical Jurisprudence*, by Paris and Foublanque, Vol. II. p. 22.

whereby, if a permanent cure could not be effected, life and intellect might perhaps in many cases (and with infinite advantage in so sudden a malady as apoplexy,) be protracted, will, I am well aware, find no favour with such members of the profession as were amused with the proposition which I made some twenty years ago to extract urinary calculus without any dangerous cutting; and who, at a later period, ridiculed the idea of saving life by extirpating the diseased ovary.

The benefit that chemistry has conferred on therapeutics, not only by presenting new substances or new combinations, but by pointing out the modes by which articles already in use may be prepared so as best to fulfil the intentions of the prescriber, is too well known to require any comment on the present occasion. Of that to be obtained from mechanics by improving the apparatus employed, a better illustration cannot be adduced than that of the substitution of fluid pressure for the various means hitherto employed to answer the same purposes. By this substitution, not only are the indications of cure more completely carried into effect, thus facilitating the cure, and preventing suffering during its course; but by the superiority of the new means, difficulties in the treatment are surmounted which could not be overcome by former means. Fluid pressure, for example, when applied to the scirrhus breast, from its exciting so little irritation in consequence of the uniformity of its action, and the ease, comparatively, with which it may be controlled, can be continued much longer and less interruptedly than the pressure of the bandage; and from the same qualities, this kind of pressure may often be used as a means of support to weakened parts where bandages are totally inadmissible. As a means of dilatation the advantages of fluid pressure are not less conspicuous, and are well worth obtaining, though at the cost of a little trouble from the complexity of the apparatus, on the part of the surgeon. In the removal of constrictions or narrowings from the larger accessible canals of the body, fluid pressure possesses so much superiority over the whole class of the wedge-acting instruments used in such

cases, as respects speed and completeness of operation as well as safety, that, I doubt not, it will be ere long matter of surprise that so much trouble had been necessary to render general its substitution for these means; and to silence the objections which ignorance, indolence, a prejudice against whatever is new, or even more creditable causes, had raised against it.

NOTE.—One would think that before going into details respecting the action of an instrument used in surgery and denying its advantages over other means, the person so doing would, if he had not actually used the instrument, at least make a point of seeing it. Yet from some observations on the fluid dilator, by Sir Benjamin Brodie, in a recent publication of his, there are grounds for doubting whether he had even this acquaintance with what he criticises, for he states that the fluid dilator must be useless in cases of narrow stricture on account of its bulk, which cannot be supposed to be less, he says, than a middle sized bougie. It is singular that his own description of the instrument, viz. "a tube of varnished silk, which is to be introduced into the stricture, and then dilated by impelling air into it by a syringe," should not have prevented his falling into this error: for it is obvious that such a tube, if rolled upon itself, when covered with adhesive matter, as a sheet of paper or parchment is rolled, or as waxcloth is rolled in the manufacture of the common bougie, cannot be larger than the same piece of cloth rolled into the form of the smallest bougie. But dilators of a size so small as this are seldom required; and that they may be as smooth as possible—as smooth as the mucous membrane of the urethra itself—it is better to cover as well as to line the silk tube by a thin piece of gut.

It is in removing a stricture completely, or to a greater extent at least, and more speedily and with less irritation than can be effected by other means, that the advantage of fluid pressure is most conspicuous. This alleged superiority is disputed by Sir Benjamin, who states, first, that he is not satisfied that bougies cannot dilate to the same extent; and, secondly, that dilatation beyond a certain degree, when effected by bougies, he has found more injurious than useful. To decide the

question of the power of dilatation by the two methods, I would wish nothing more than that both instruments should be seen, or their description and mode of action, at least, clearly understood; and as to the second objection, I would ask if it be logical to compare the action of an instrument which produces much irritation when employed of a large size, (as it must necessarily dilate the whole of the sound, as well as the diseased part of the canal), and whose mode of operation is very different, with that of an instrument which acts on little else than the diseased part? With as much propriety may castor and croton oil be compared together, as the fluid dilator and the bougie; but they surely differ so exceedingly in the degree of irritation which they severally produce, as would make any comparison between them preposterous. But Sir Benjamin Brodie is of opinion that, like the disease of the joints above alluded to, stricture is incurable—that patients with stricture must be patients for life; and he is content therefore with the employment of a palliative means of very inferior description.

If stricture be indeed incurable, if its removal be beyond the power of any mechanism or any medicinal agency addressed to the vitality of the diseased structure, it is a fact much to be lamented; for it is obvious that any long-continued source of irritation in the urethra must eventually have the most pernicious consequences on the contiguous and sympathizing parts—on the prostate gland, bladder, or kidneys. I believe that Sir Benjamin has taken too gloomy a view of the surgery of this department; but even granting that every means of dilatation is but a palliative remedy, surely, as our object is to remove a source of irritation and danger, that which removes it with most expedition, at the least risk to the patient, and to the greatest extent, consistently with this safety, should be preferred.

It is with much pain that I have entered upon this subject, and animadverted on a want of candour and correctness in the reasoning of one who has so long been deemed a high authority in the profession. But when “authority” is used to crush what a prolonged experience has proved to be an

improvement of the highest order, the interests of humanity demand that an inquiry should be made into the grounds on which its judgment is founded. A critic in the *London Medical Journal* (No. 269) spoke of the application of fluid pressure to the diseases of the urethra as constituting a new era in their treatment, and he did not speak without practical experience of its use, for it had been adopted in his own case. How differently does the writer proceed who, granting that he may have seen the instrument, has assuredly never employed it; and yet, from comparing it with what it does not resemble, condemns it!

Having quoted Sir B. Brodie’s imperfect description of the fluid dilator, it may be necessary to mention a few more particulars with regard to its construction and use, in order to prevent any misconception on the subject. When it is merely a tube of varnished silk, and of a size, in its distended state, less than the natural diameter of the urethra, the tube may be of sufficient length to reach from the orifice of the urethra to a little beyond the stricture; and when rolled upon itself in its collapsed state, in order to render it smooth and sufficiently stiff for insertion, it has in every respect the appearance of a wax bougie. It is, in fact, a wax bougie capable of swelling with any desirable degree of power after it has passed within the stricture. Such is one form of the instrument; but that which is usually more convenient consists of a short and smooth dilatable tube, of the required diameter, tied upon the end of a metallic tube, which directs it to the constricted portion of the urethra, and conducts the distending fluid to it. This fluid, consisting of thick mucilage and a portion of air, is gradually introduced, according to the feelings of the patient, until a degree of hardness is produced in the distended membranous tube which no stricture can withstand. The patient may himself regulate the pressure by raising or depressing the screw which moves the piston of the syringe; and on account of the power which a screw piston-rod affords, a syringe capable of holding a large supply of liquid may be used. The fluid dilator, from its smoothness and pliancy, is, in most cases, as easily passed into the stricture

as a common bougie; sometimes, indeed, from its possession of peculiar qualities in this respect, more easily.

Another improvement of means already in use, which I consider to be an accession of considerable importance to therapeutics, from the power which it confers of greatly extending the use of a very valuable remedy, is the mode which I have adopted of applying cold locally to prevent or remove inflammation, hæmorrhage, &c. in a very great variety of cases.

The local application of cold furnishes one of the best examples of a remedy originating in the instinctive dictates of nature; but from the mode in which it has hitherto been made, I doubt whether as much harm has not been produced by it as benefit. The usual mode is to place a rag dipped in cold water, pure or medicated, upon the part, renewing it at intervals according as it becomes heated. This is evidently not a continued application of cold, but a series of changes of temperature, and is likely enough, in many cases, to cause a very prejudicial effect. If ice be substituted, the cold may be too great, and the mischief be increased; and cold affusion, or irrigation, as it has been termed, though often a useful substitute, can only be applied to certain parts of the body, and even to these with much trouble and difficulty. What I have found a perfect mode of applying cold, is to cover the part with a very thin bladder, of the requisite dimensions, containing a small quantity of water of the desired temperature, which is constantly renewed by establishing a current through the bladder by means of two pewter tubes; one connected with a reservoir, and having a stop-cock at its end to regulate the stream; the other leading to a waste vessel. The elevation of the waste-pipe regulates the quantity of water in the bladder; and as, from the change of position of the patient, this elevation must be frequently altered, it is convenient to rest the extremity of the pipe on the sliding ring of a common retort stand.

By this apparatus the temperature can be regulated with the greatest precision, and (when such a test should guide us) water of that temperature can be chosen, whether high or low, which is most agreeable to the patient's feelings. If sudden and severe cold is

desirable, very cold water running rapidly through the bladder will reduce the temperature much more rapidly than the application of ice. Cold and heat can thus be conveniently applied (by fixing the ends of the supply and waste pipes together, and tying them into one end at the bladder) to various internal as well as external parts; the cold, to check hæmorrhage, as in menorrhagia; the heat, to promote the natural discharge of the part, as in amenorrhœa. When used to restrain hæmorrhage, the plugging of the passage by the distended bladder is an important part of the treatment, and is much better adapted for its purpose than the irritating and less manageable expedients hitherto employed.

A modification of this method of applying cold, contrived for the purpose of combining pressure with it, has been used, on my recommendation, and with great advantage, in a case of strangulated hernia. Cold and pressure are each separately of great efficacy in this disease as means of obviating the necessity of a dangerous operation; but when their forces are combined, this object will be accomplished, not only more certainly, but more speedily.

PRACTICAL REMARKS

ON THE VALUE OF THE OPERATION OF PERFORATING THE WALL OF THE CHEST INTO A TUBERCULAR CAVITY,

FOR THE RELIEF OR CURE OF TUBERCULAR
PHTHISIS,

With Comments on the Case of J. G.

By E. O. HOCKEN, M.D.

Physician to the Blenheim Street Infirmary, &c.

SOME months back my attention was directed to the propriety and safety of making a free communication through the wall of the chest with a tubercular cavern in the lung, (as a means of affording relief, or of effecting a cure) by reading some account of a discussion on the subject. Since that period I have learnt that the subject is by no means new, either in theory, or in actual practice; Dr. Barry, of Dublin,* having proposed, and successfully performed the operation more than a cen-

* A Treatise on Consumption of the Lungs. 1726. A Treatise on three different Digestions, &c. 1763.

tury ago. For this information I am indebted to Dr. Hastings. The suggestion appeared to me of considerable value, at the same time that I felt convinced that the operation would be applicable only to certain cases, and that it would almost to a certainty fail in producing a cure, unless at the same time some plan of medical treatment were adopted capable of assisting the curative efforts of nature, and of suspending the further deposition of tubercle, as well as of removing any traces of disease which might exist with the cavern in other parts of the lungs. From careful, and, I trust, perfectly impartial trials of the *medicinal naphtha*,* I was convinced that the profession possessed in it a remedy capable of producing all these results. Impressed with these considerations, I suggested the combination of surgical proceedings with medicinal naphtha, and other remedial measures, in my "Practical Inquiry into the Value of Medicinal Naphtha in Tubercular Phthisis," written about three months since, (September, 1844). In commenting on a case of phthisis with laryngeal disease, I remarked at p. 60, that "naphtha, although it relieved the chest symptoms, exerted no beneficial influence on the laryngeal disease. Supposing such a case to occur, in which auscultation proved that the phthisical state of the lung might be cured, and was already benefited by the treatment, would it not be allowable for the surgeon to perform the operation of tracheotomy, in aid of the curative influence of medicinal measures?"

"In speaking of surgical operations in aid of the physician's attempts to direct the efforts of nature into a proper and healthy channel, I may remark that the operation recently proposed of making a free external communication through the wall of the chest, with a phthisical cavity of large size, replete with morbid secretions, is (if it could be effected safely) likely to render the case more curable, provided the extent of disease present, and the predispo-

sition of the patient, allow the smallest shadow of hope to remain."

At the time this paragraph was written, I imagined that the operation would prove beneficial much in the same way, and on the same principle, that the surgeon gives relief in deep-seated and diffused abscesses; viz., by freely opening up sinuses, and dividing fistulous tracts, in order to allow the secretions of the sac of the abscess to escape freely, and to relieve the irritation produced by the passage of these matters through narrow and circuitous routes. Hence I concluded that it would be more applicable to cases of cavern furnishing the signs of abundant liquid contents, and where a large quantity of muco-purulent matters had to be expectorated through the bronchi; and it was from these considerations that I concluded the opening should be made into the cavern at the most depending position, and, at the same time, at a point where it was most probable from the auscultatory phenomena it was situated nearest to the surface.

In the early part of the month of November, Dr. Hastings informed me that he had a patient in an advanced stage of consumption, who was suffering from the effects of a very large cavity in his left lung, but where the signs of tubercular disease were comparatively slight on the right side; and showed me a letter from the patient (a well-educated intelligent man) stating his willingness to submit to the operation, notwithstanding its risks, provided it held out any reasonable chance of ultimate good. In my conference with Dr. Hastings on the subject, I stated to him the views I entertained, and my willingness to assist him, to the utmost of my power, in carrying these opinions into execution.

On the following morning, I also talked the matter carefully over with my friend Mr. Storks; and it was subsequently arranged by Dr. Hastings, that myself and Mr. Storks should meet him to examine the patient, and decide on the best modes of operating, and the situation to be selected for the opening, on the following Monday. Accordingly, on the 11th of November, I met Dr. Hastings and Mr. Storks, and with them very carefully examined the patient's chest, and fully arranged the steps most likely to be successful in the operation, which was fixed for

* Till recently I feel convinced that scarcely any one has tried the *genuine Medicinal Naphtha*—it being impossible to obtain it (or only as an accident) from any house in London, but at White's, Piccadilly, two doors from the Haymarket. Very recently, Mr. Hooper, of 7, Pall Mall East, has succeeded in discovering where he can obtain a supply. He informed me that, but for an accidental circumstance, he would have searched London over without discovering any druggist who sold the right spirit.

the following Friday. On the 15th, immediately previous to the operation, I again ausculted the patient's chest, and selected (agreeably also to the opinions of Dr. Hastings and Mr. Storks) a spot parallel with the left nipple, at the upper edge of the fourth rib, on a level with, but considerably to the left of the situation of the heart. The operation was then performed by Mr. Storks, and (as an unprejudiced observer) I may be allowed to say, with that skill and dexterity which I have seen him exhibit on several other occasions. Since that event nearly to the present time, I have most closely and carefully watched the case, attending two or three times daily with Dr. Hastings and Mr. Storks; and hence I may be allowed perhaps to make a few comments on the applicability of the operation, and on this particular case (the case of J. G.) referring for minutiae to the report of the daily history, published in the *Med. Gazette*, of Dec. 20th, by Dr. Hastings and Mr. Storks, to the accuracy and impartiality of which I would add my humble testimony.

It appears to me that the comparative condition of the patient's chest immediately previous to the operation, and at the present time, is of considerable importance in judging of the value of the operation. I will therefore mention the signs which were present on the 11th of November, and the state of the chest as it existed on the 17th of December.

11th Nov.—*Physical signs.* Flattening of the antero-superior parts of the left side of the chest, with diminished respiratory play, but with bulging and elevation of the upper intercostal space with each inspiration, and depression with expiration, especially marked in the first and second intercostal spaces; considerable dullness on percussion over the clavicle and over the whole surface from the clavicle as low as the fifth rib: powerful, blowing, cavernous breathing, which seemed to be pulled into and out of the ear, over the dull portions, with complete, reverberating, loud pectoriloquy, unmixed with any moist sounds. These signs were decidedly most superficial over the third intercostal space, parallel with the left nipple. The same signs existed in the left axillary and upper part of the sub-axillary regions, but less loud and superficial. Posteriorly there was con-

siderable dullness over the scapular region, with cavernous breathing and pectoriloquy. Beneath the scapula there was some healthy respiratory murmur, also in the lower part of the sub-axillary region.

Right side anteriorly.—This side possessed the natural amount of prominence, extensive respiratory movements, and a perfectly normal degree of resonance. Respiratory murmurs slightly harsh and bronchial over the sub-clavicular region, especially beneath the sternal half of the clavicle; increased resonance of the voice and heart-sounds, over the same region, quite unmixed with any other moist or dry sounds. Laterally and posteriorly there was no evidence of disease.

Dec. 17th.—*Right side.* This side of the chest yielded a perfectly normal amount of resonance on percussion, and its motions were excellent. The voice was still somewhat bronchial beneath the sternal half of the clavicle, and resonant over the sub-clavicular region near the sternum. The respiratory murmurs were nearly healthy—only slightly harsh—over this region, where they had previously been bronchial, except beneath the sternal half of the clavicle, where there is still some blowing and bronchial sound. In all other parts perfectly healthy.

Left side.—During the progress of the case there has been a gradual process of falling in of the walls of the chest over the cavity, which was, however, much more marked about three weeks since than at present, owing to the great prominence of the clavicle which existed at that time, from the collapse of parts above and beneath it. There was much less intercostal motion than on the previous examination, but the motions of the side in respiration remained the same. The amount of dullness on percussion remained nearly as before, and occupied the same regions, but there was a marked difference in the auscultatory phenomena. The breathing was still cavernous over the upper portions of the left side of the chest, but instead of being noisy and with force, apparently pulled into and out of the ear, as on the examination made previous to the operation it was quiet and gentle, and might have been mistaken by a careless auscultator for healthy breathing, unless the patient breathed more deeply

than natural—indeed, so much so, that one gentleman of deservedly high reputation actually fell into this error on first applying his ear to the chest. The voice, instead of passing directly into the ear with a clear reverberating sound, did not amount to pectoriloquy, but consisted of a loud resonance, but without any articulate sounds passing into the ear. Below, laterally and posteriorly, there was healthy respiratory murmur.

My diagnosis of the case previous to the operation was—a very large empty cavern in the upper part of the left lung—probably occupying the whole of the upper lobe—extending very superficially, especially in front, and evidently in free communication with one or more bronchi: lower portions of the inferior lobe healthy. Some tubercular disease of the upper part of the right lung.

The changes which had been effected between the dates of Nov. 11th and Dec. 17th, were, that the cavity was retained in a state of comparative repose, the walls being no longer powerfully and constantly separated by each inspiration, whilst the little air which was drawn in by a forced inspiration, as in coughing, &c., readily escaped through the tube. From this favourable state of things the size of the cavity had evidently much diminished, (perhaps from the gradual approximation of its walls) and I have little doubt that a process of healing was in progress within the cavity itself: proved, I think, by the adhesions which constantly took place during the progress of the case, between the tube (which passed about an inch and half into the cavity) and the soft parts with which it was in contact. During the dressing of the wound some small masses of organised lymph were several times withdrawn in the extremity of the gum-elastic tube, which had partially obstructed the instrument by stretching across its calibre, between the apertures in its sides. This quiescent state of the cavern, and the diminution of its size, which had evidently taken place, both by approximation of its walls, and a process of healing, fully account for the removal of pectoriloquy, and the great changes effected in the characters of the cavernous respiration. The slight disease present in the right lung was also diminishing and in process of

cure. One gentleman, who has ausculted the patient twice during the last three weeks, imagined that the disease of the right lung was increasing; but on what grounds I am at a loss to conceive. My own examinations of the patient's chest have been made with the greatest care, and coincide fully with the opinion of all those who have similarly examined the patient, with this one exception.

The highly satisfactory state of the general symptoms attest the beneficial changes which have been effected in the local disease; I would especially refer to the number of the respirations in a minute before the operation (32) and subsequently, being at present from 16 to 18 in the minute; also the complete absence of dyspnoea and hectic; and the comparative freedom from cough, as well as from anything but simple mucous expectoration in small quantity; and no discharge, or very trifling, through the tube from the cavity. The pulse also has regained its healthy standard.

These are not the symptoms of advancing disease, but rather those resulting from a complete relief of the constitutional and local irritation, which had previously worn down the system, and were hurrying the patient to the grave. So far from any proof of advancing disease, the chest symptoms become daily more favourable, and the patient gains flesh, health, and strength. These remarks lead me naturally to speak of the

Manner in which the operation proves beneficial—I have already mentioned the manner in which I believed the operation would act beneficially before I attended the case of J. G.; since that time, however, my views have undergone some modifications, which I think of considerable importance in practice. My former opinion was, that the great objects of the operation were to allow the secretions of the cavern to escape freely, and thus to prevent any accumulation in the diseased lung, and give relief to that irritation which is produced by the passage of such matters through narrow and circuitous routes. Hence I imagined the opening ought to be made in the most depending position.

My present belief is, that when a free communication is formed with a cavern through the wall of the chest, a new

action is produced in the sides of the cavity, of a healthy or reparative nature—totally opposed to the diseased conditions which previously existed, and which tended only to the increase of the complaint and to the death of the patient. The presence of the previously unhealthy action in the cavern is manifested in the severe local and constitutional irritation which exists: producing in the first instance cough, more or less unhealthy muco-purulent secretion (which in the case of J. G. was expectorated as fast as it was formed, amounting to about 3ij. daily), constant dyspnoea and breathlessness, with a necessity for frequent respiration; in the second giving rise to a state of severe hectic, rapidity of pulse, great emaciation, and complete loss of strength, &c. Consumptive patients rarely die from the actual amount of disease present not leaving a sufficiency of lung to carry on life, but from the amount of irritation which that disease occasions, wearing down the vital resistance, and hurrying the patient to an untimely grave. As soon as the operation is performed in a judiciously selected patient, this state of irritation, which, in the stage of cavern, is the *fons et origo mali*, is removed, (vide the case of J. G.): the cough, dyspnoea, expectoration, and frequent respiration are relieved, and altered in character—for the cavern either secretes nothing, or mucus in very diminished quantities. In like manner also the constitutional symptoms: the pulse falls to its healthy standard; the hectic disappears, and as the patient recovers from the immediate effects of the operation (unless any accidental circumstances keep him back), he gains flesh, appetite, and strength, with a due performance of the functions, and with the feelings of health.

The manner in which this healthy action is induced in the cavern by making an opening into it through the wall of the chest, may probably be explained on the same principle that accounts for the cure of some forms of laryngeal disease acute or chronic. As long as the larynx performs its functions in respiration it forms a highly important part in the economy, and is more or less constantly disturbed by the ingress and egress of air. If under these circumstances disease be set up in the organ, there is that amount of irri-

tation present which will prove sufficient to keep up and increase it—so as generally to set medicine at defiance—and ultimately, either in a very short or a longer period, prove the cause of death, or be cured by the operation of tracheotomy. By this operation the larynx is cut off from performing any important office in the economy, and is placed in a state of quiet; inducing immediately a complete change in the character of its diseases, which become as curable and as unimportant as a similar disease would be in the mouth, or in any other non-vital part of the body. So, in like manner, the tubercular disease in phthisis is situated in a vital organ of the highest importance, and the cavern is subject to constant disturbance in the respiratory movements, and from the ingress and egress of air. By making a free opening into any part of this cavern through the wall of the chest, it is cut off from performing any part of the respiratory functions; its sympathetic relations with the rest of the system are completely altered (having just the same amount of sympathetic relation with the constitution as such disease would have if situated in a non-vital part), the diseased parts are placed in a state of comparative rest, and the tubercular cavity becomes as curable as it would be if situated in any part of little importance in the economy.

[To be continued.]

RECORD OF CASES.

By THOMAS MAYO, M.D. F.R.S.

Physician to the Infirmary of St. Marylebone.

[Continued from p. 354.]

(For the London Medical Gazette).

JULIA HUNTER, aged 39, was admitted into the Infirmary April 15th, 1844, having had a cough for two weeks, and occasional hæmoptysis in that time. She had been confined eleven months before, and had suckled her infant up to the last two months. She was fair, of average stoutness, and apparent strength. The pulse was small; the skin cool; the dyspnoea considerable. Mucous crepitation was extensively diffused through the lungs, (the expansion of the ribs was on both sides defective), in spite of which much ve-

sicular breathing was audible; no marked dulness; the sputa mucous, not frothy, containing occasionally dark lumps of blood. Such was the character of the pulmonary symptoms throughout this illness. It appeared that she had not menstruated since her confinement. The bowels were easily kept open. She was ordered the Mist. Antimonial. c. Vin. Ipecac. ℥xv. 6tis., the Pil. Hyd. Chlorid. Antimon. et Opii 8vis., horis and was cupped ad 3vijj. inter scapulas.

April 20th.—Shooting pain of head, and heaviness, which, she says, have existed some time, are increasing; the breathing is better.

Hirud. vj. temporibus. Pil. Hyd. Chlor. Antimon. sine Opio, ter.

23d.—This morning she had become suddenly insensible; she was very purple, and foamed at the mouth; this state of insensibility continuing to the evening, with three intermediate fits. She was cupped ad 3vijj., since which I found, on the 24th, that no paroxysm had recurred. She was then breathing easily, and consciousness had returned.

Hirud. vj. vertici raso, et post hirud. Emp. Lyttæ.

27th.—Consciousness had entirely returned; some pain and weight of head still complained of, chiefly in the forehead. Tongue moist; bowels open; countenance composed.

Whatever pain the patient complained of in the thorax was on the left side, below the inferior edge of the scapula; on this side she was generally unable to lie, and on this side also the crepitus above mentioned was most marked. For pain and dyspnœa referred thither, she was cupped on the 29th ad 3vijj.

30th.—She expressed herself relieved principally in the head; but then, and frequently afterwards, complained of excessive hunger. The pulse was small; more vesicularity on the left side than before. She went on with little change to May 16th. The powders of Calomel and Pulv. Antim. continued as above, and the bowels kept gently open. On that day she became delirious, and was cupped ad 3x. temporibus.

May 18th.—Pulse still sharp and oppressed. Hirud. x. dorso.

19th.—Relieved by leeches; had

some sensations as of approaching catamenia.

Lactis, 3vj.; Sp. Ammoniac. C. 5ij. pro injectione utend.

22d.—Head better; no increase of the above sensations of approaching catamenia. Let the injection be discontinued.

June 1st.—I note that the breathing on the two sides is now nearly equal; both crepitous in parts, but vesicular penetration in both increased. Urine not deficient; legs and thighs becoming œdematous.

Sumat Hyd. Chlorid. gr. iij.; Scillœ Bulb. gr. ij. M.

Omittat. pulv. olim præscript.

6th.—Mouth affected.

Sumat pil. Scillæ C. bis. Omisso Hydr. Chlorid.

11th.—Œdema increasing; dyspnœa and pain diminishing.

16th.—Less well; delirious; sudden and violent exclamations of fear; rapid breathing, which is rough, crepitous, and excited under left scapula; sputa muco-purulent.

Cucurb. cruentæ nuchæ ad 3vijj. Hyd. Chlorid. gr. iij. h. s.

18th.—Delirium has ceased, but sharp pain in the temples is complained of.

From this time to the death of the patient, which occurred September 3d, under symptoms of extensive sphacelation in the legs, dyspnœa; and latterly orthopnœa, pain, and oppression of the head, with delirium and pain on the left side of the thorax returned with intervals of comparative ease; the head symptoms less severe than at first. The failing powers of the patient made the abstraction of blood now hazardous, and she found considerable relief of dyspnœa from enemata containing Sp. Terebinthin. given under exacerbations. As a remedy which, during the last month of her life, contributed much to the patient's comfort, I may mention the following:—

R. Misturæ Tragacanth. 3iss.; Potassæ Acetat. 3ss.; Vin. Colchici, ℥x.; Træ. Cardamom. C. 3j. 8vis horis sumpt.

Autopsy.—Brain normal, except a small portion of a rusty colour, but not softened, in the right corpus striatum.

Both lungs adherent to pleura; the left lung universally; both extensively

engouées, of a dark red colour; some small portions in a state of red hepatization. Heart everywhere adherent to pericardium; the walls of the left ventricle hypertrophied (concentrically); valves normal, except in some small vegetations near the edge of the mitral.

The kidneys were atrophied and granular. Other organs healthy.

To my notes on the above case I must add, that the orthopnea therein mentioned towards its conclusion, existed during the whole of it, though increased near its close; and that by subsequent inquiries from the patient's husband, I learned that she was not known to have ever had any rheumatic attack; but that for four years she had been an ailing woman, with what was called asthma. This would lead us to suppose that the pericardial inflammation, as also that of the other serous membrane, neither of them recent in character, was connected with the granular degeneration of the kidney. It would appear that, in spite of this state, she became pregnant, was confined, and nursed her infant for nine months; and finally sunk from the effects of a catarrhal affection, which, in the embarrassed state of her circulation, she was unable to shake off. The whole case affords at least an interesting illustration of the capacity for living often exhibited under severe structural disease.

I have no record of the phenomena the heart itself during the progress of this case.

The statement of the appearances on dissection was furnished me by Dr. Boyd.

[To be continued.]

ABSENCE OF A PORTION OF THE BRAIN.

To the Editor of the Medical Gazette.

SIR,

I SHALL feel obliged by the insertion of a few notes of a case that recently came under my notice, and which seems to me to have some bearing upon the subject of Mr. Solly's communication, at page 245 of the present volume of the *GAZETTE*.

Mrs. W.'s infant was born Nov. 20, 1843, and seemed to thrive very well

until the beginning of February, 1844, when it was seized with a violent convulsive fit, which continued a considerable time. Similar fits, of shorter duration, recurred again during the rest of its life, several times daily, with intervals of apparently natural sleep. They seldom came on during the night. No determination to the head, or plethoric condition of the system, existed; the child sucked well, grew, and in fact seemed quite well, with the exception of these attacks, and a rather obstinate constipation. No means that I tried seemed to have any effect in reducing the number of the fits, although the movements of the limbs were sometimes less violent at times; and other advisers, whom the mother afterwards sought, were as unsuccessful.

I saw the child again in July, when it was plump, and as well grown as it should be for its age, except that its chest was very narrow. It continued to suck well. The mother states it neither does, or ever has taken any notice whatever, even when tried with the other children. She doubts if it sees, as a brilliant light produces no dazzling effect upon it. No teeth have appeared. The convulsions continue as before, sometimes with less, sometimes with greater frequency; the child sleeping tranquilly in the interim.

The child died Nov. 16th. For a month or two previously, the attacks of convulsions had diminished in number greatly, and for the last fortnight had disappeared, being replaced, however, first, by a constant restlessness, and afterwards by a comatose state. During the last few weeks it had become much emaciated, and the left eye projected considerably from its socket. Two teeth only had been cut. From the day of its birth to that of its death, the child, even when quite awake, and apparently perfectly easy and well, manifested no sign whatever of recognizing persons or objects.

I examined the head twenty-four hours after death, assisted by Mr. J. Griffith, of University College. Upon removing the skull-cap, the vessels were observed considerably engorged, and upon the division of the membranes a considerable quantity of fluid escaped. The source of this was not at first obvious; but as the incision into the dura mater was made near the point

where the two hemispheres come into contact, I doubt not it followed their separation. In fact, upon stretching them asunder, we looked at once into the cavities of the ventricles, the corpus callosum, septum lucidum, and fornix, being absent, with the exception of two narrow slips of the first named portion, a few lines in breadth, stretching between the anterior portions of each hemisphere. Just anterior to the corpora quadrigemina, lying in a small cavity large enough to contain the tip of the little finger, was an hydatid, about the size of a small hazel-nut, having much smaller ones adhering to it, and filled with a gelatinous fluid. The optic nerves were remarkably small throughout their whole course, and the tubercula quadrigemina were much smaller than ordinary. A small quantity of fluid only was found in the ventricles. The cerebral substance was not injected, but most remarkably firm upon incision; while the medulla oblongata and superior portion of the medulla spinalis cut just like a piece of cartilage.—I am, sir,

Your obedient servant,

JOHN CHATTO.

Great Coram Street,
Dec. 30, 1844.

ANALYSES AND NOTICES OF BOOKS.

“L’auteur se tue à allonger ce que le lecteur se tue à abréger.”—D’ALEMBERT.

Medical Report of the Case of Miss H—M—. By T. M. GREENHOW, Fellow of the Royal College of Surgeons of England; Senior Surgeon to the Newcastle-upon-Tyne Infirmary, and Eye Infirmary. 8vo.

LORD BYRON says “time at last sets all things even.” The adage seems to hold good with respect to the human uterus, judging from Mr. Greenhow’s very clear and rational statement of the case of Miss H—M—, published with the entire concurrence of the patient.

“In a letter from Venice, dated June 14, 1839, Miss H. M., æt. 37, first communicated to me her early feelings of indisposition. During the preceding year she had been sensible of a ‘great failure of nerve and spirits, and of strength.’ Frequently she experienced sharp pain in the uterine region. The catamenia became more frequent,

occurring every two or three weeks; and a very irritating discharge, of a brown or yellowish colour, took place in the intervals.

“The irregular uterine discharges continued, occasionally mixed with clotted blood, and she suffered from many distressing nervous symptoms, evidently arising from uterine irritation; ‘inability to stand or walk, aching and weariness of the back, extending down the legs to the heels;’ ‘tenderness and pain, on pressure, in the left groin, extending by the hip to the back. The spirits became much depressed, and the power of enjoyment was gone.’ At the same time, ‘a membranous substance, like the end of a little finger,’ was discovered projecting from the os uteri.”

It would appear from the extract of a letter dated Lucerne, July 6, 1839, that retroversion of the uterus had taken place about that period. At the end of the same month Miss H. M. arrived in Newcastle, and placed herself under Mr. Greenhow’s care, labouring under symptoms referrible to some organic or functional derangement of the uterus. On examination that organ “was found large, retroverted, and fixed low down in the vagina, the os and cervix uteri occupying the anterior part of the cavity, and the body and fundus of the organ passing horizontally backwards, till the latter approached the sacrum. The enlarged uterus thus occupying the antero-posterior diameter of the pelvis, pressed, respectively, against the urethra and neck of the bladder and the lower part of the rectum; and the embarrassment occasioned by this pressure produced corresponding symptoms, which were often the occasion of great uneasiness and inconvenience. While the fundus uteri extended backwards towards the sacrum, the cervix was bent downwards behind the pubes, nearly at a right angle, and hanging from the lip was a small polypus, which was soon removed; but without any alleviation of symptoms.”

Ere long the patient began to suffer from oppressive sickness, frequently amounting to retching, together with much difficulty in micturition and in emptying the bowels, occasioned by the pressure of the uterine tumours, as also from distressing pains down the lower extremities, frequently extending to the heels. “The abdomen became con-

siderably distended during the progress of these symptoms; but this arose more from a general distension and fulness of the bowels, from flatus and other contents, than the enlargement of the uterus, which could never be felt rising above the brim of the pelvis: though its increased size, doubtless, by pushing the abdominal viscera upwards, tended in some measure to produce a general enlargement of the figure.

"It not unfrequently happened, although, by the use of gentle aperients or emollient injections, a pretty regular action of the bowels was secured, that a gradual accumulation of their contents took place, giving rise to increased distress; which required the use of more active purgatives for its relief." * * *

"The constant and distressing aching in the back rendered it painful to rest upon the sacrum in reclining upon the sofa; and some relief was obtained by resting in a prone position. A couch, contrived for this purpose, was found a source of much comfort to the patient."

In September, 1841, Sir Charles M. Clark, after a very careful investigation of the case, gave the following opinion—"It was my intention, to say that I perfectly agreed with you as to the nature of the complaint, that the disease was an enlargement of the body of the uterus; that the neck of that organ was perfectly healthy; that although the majority of these cases of enlargement of the body of the uterus did not yield to external applications or to internal remedies, that, nevertheless, the disorder produced mechanical symptoms only, and *did not lead to any fatal result*, to which termination disease of the *neck* of the uterus did lead.

"Farther, I mentioned that in an instance or two I *had* known such complaints as Miss M.'s subside, and that I would suggest the employment of certain means for this desirable purpose."

The means proposed by Sir C. M. Clark was the continued external use of iodine ointment, to this the patient objected: but was prevailed upon to take iodide of iron, in the use of which she persevered, with the exception of a few short intervals, until July or August, 1844. By this medicine the distressing sickness was greatly mitigated, the appetite improved, some morbid feelings were alleviated, and an increased tone of general bodily health as well as of

mental energy showed itself, as may be inferred from the following extract from a note written in September, 1843:—"I suppose I owe my much improved comfort mainly to them (the pills of iodide of iron); indeed it is very great. The pulling and sinking—the mechanical troubles as one may call them—of course continue, but the almost total absence of sickness, and the striking lessening of the 'distress,' are such a comfort to me!"

On the 2d of April, 1844, Mr. Greenhow was first enabled to detect a slight change in the condition of the uterus. The attachment of the fundus was less fixed, and it could be slightly raised from its position. A membranous pedicle, which protruded from the interior of the uterus, but unattached to the neck, previously discovered, could still be felt, and the general position of the organ remained as before.

"In the beginning of June, Miss M. suffered much from an attack of indigestion, with disordered and loaded bowels. The symptoms proper to the organic affection, especially the distressing pain in the back, were for a time increased; and while proper means were resorted to for the correction of visceral derangement, a plaster with belladonna was applied to the sacral region, from which but slight relief was obtained. The unwonted symptoms of indisposition had subsided, when, on June 22d, the mesmeric treatment was commenced, of which a full account has been published in the *Athenæum* by Miss M. From this time she ceased to be properly under my care, though her accustomed remedies were not yet laid aside. I shall therefore pass over the interval till September 4th, on which day I carefully repeated my examination, and found, as on April 2d, that the posterior connections of the uterus were less fixed than formerly. The retroversion continues, but the fundus, which rests against the rectum and sacrum, feels looser, and admits of being raised to some extent with the finger in vaginam.

"The uterus feels altogether less firm, and more yielding in its substance, and the os uteri is to a certain extent dilatable, yielding to the finger in a slight degree more than formerly. Within, and slightly projecting from the os uteri, can be felt *two* substances, which convey to the finger a sensation

as if two lumbrici, of moderate size, hung through the mouth of the uterus. These membranous projecting bodies are said, on pressure, occasionally to exude a reddish discharge. In addition to the knowledge obtained by this examination, Miss M. supplied me with the following reports of herself, at this and several succeeding visits which I made her, previous to the next and final examination into the pathological condition of the uterus, on December 6th. On this day (September 4th), she informed me that the catamenia, which for many years had taken place at shorter intervals than natural, every two or three weeks) have resumed their natural course. That the breasts have increased in bulk. The pills of Iodide of Iron, all aperients, have been discontinued, the bowels having lately acted with ease and regularity. The use of opiates has been greatly diminished by Enema, and internally, altogether omitted. The sickness and other gastric inconveniences have ceased; the irritation in the rectum and neck of the bladder are no longer complained of;—quietude and repose have succeeded to restlessness and irritability; and the nervous system has acquired a greatly improved tone.”

Progressive amelioration took place. Upon the 6th of December another examination was made. “The fundus uteri is more disengaged than at the last examination, and admits of being raised somewhat higher. It is certainly *less fixed*, and in this respect has improved at each time of examination since April 2d, when the first degree of improvement was observed. The retroversion continues, the fundus still extending towards the sacrum, while the os uteri approaches the pubes—the organ remains large and firm, and is yet turned back nearly at a right angle from the cervix uteri. The two membranous pedicles remain hanging out of the os uteri, as at the last examination.”

The health is represented as quite good, and the catamenia as regular, the nervous pains and irritation having all subsided. Knowing well that no symptoms of malignant disease of the affected organ existed, Mr. Greenhow always believed that a time would arrive when his patient would be relieved of most of her distressing symptoms, and released from her long continued

confinement; that some day, probably before long, would arrive when Miss M. should take up her bed and walk.

As regards the pathology of the case, the experienced practitioner will conclude “that the condition of the uterus in December is but the natural sequel of progressive improvement begun in, or antecedent to, the month of April; and as regards the relief from the distressing nervous symptoms connected therewith, that the time had arrived when a new and powerful stimulus only was required, to enable the enthusiastic mind of my patient to shake them off.

“After bestowing my best consideration on the subject, this is the conclusion which most strongly forces itself upon my own mind.”

Galvanism, applied to the Treatment of Uterine Hemorrhage. By THOMAS RADFORD, M.D. Fellow of the Royal College of Physicians of Edinburgh, Member of the Royal College of Surgeons of England, Consulting Physician to the Manchester and Salford Lying-in Hospital, &c. &c. 1844.

DR. RADFORD, of Manchester, has ingeniously applied galvanism to obstetric practice. Being called in consultation to a case of frightful internal hæmorrhage during labour, attended with extreme exhaustion, and where the os uteri was so rigid that the advocates for delivery could not have acted without lacerating the os and cervix uteri, the author ascertained that galvanism produces an effective and powerful contraction of the uterus; and not only so as regards its tonic contraction, but that it has also the power of energetically exerting alternate contraction when applied at intervals.

“The alternate contraction excited by this agent is analogous to, and as powerful as, that which is observed in normal labour, and the tonic contraction is greater. I shall not relate cases in detail, because it would occupy too much time; but I may state that I applied galvanism in a case where the membranes were unruptured, and the membranes in a state of great inertia, and alternate contraction was immediately produced. Before this the membranes were very flaccid; but as soon as the galvanic circle was completed, they became extremely tense, and pro-

truded low down into the vagina; and this state of tension did not subside when the alternate contraction ceased, as is observed in some degree in normal labour; for although the galvanic conductors were removed, so great a degree of tonic contraction of the uterus had been induced that this membranous bag could not collapse.

"I am thus satisfied that by the application of this means we can induce such a state of tonic contraction in the uterus, that, in these extreme cases of exhaustion from hæmorrhage, the woman may be placed in such a state of safety, that delivery may be postponed until a time arrives when it can be safely accomplished, and in the meantime we can have recourse to those measures which tend to raise the vital powers."

As the evacuation of the uterus in cases of placental pre-entation, whether that evacuation be partial or entire, always proves an additional source of exhaustion, Dr. Radford considers that it would be an important point of practice to draw off the liquor amnii *gradually* as the first step in the management of the case. "For this purpose I have somewhat modified Mr. Holmes' instrument for perforating the membranes, making the canula much larger, and having an oval aperture placed on each side near its open extremity. The entire instrument consists of a canula and trocar, which latter always lies concealed within the canula, by means of a spiral spring, except when pushed out by pressure on its button-like extremity. This trocar can be entirely withdrawn from the canula; so as to leave the latter free for the passage of fluid. Now I propose to pass this instrument through the placenta into the amniotic bag, and then remove the trocar, so that the liquor amnii may escape: a plan which I prefer to rupturing the membranes at the side of the placenta, because the water in the latter case would flow too rapidly, on account of the practitioner not being able to limit the size of the opening he might make; and also because by the plan now recommended, the integrity of the membranes being preserved, the placenta is thereby maintained in a better position for acting as a tampon against the open venous apertures when the head comes to press upon it.

"In rupturing the membranes in the

ordinary method, it is quite obvious that as the connection between the membranes and placenta is broken, the latter is liable to fall down more or less into the vagina. Having thus drawn off the liquor amnii, the next step will be to introduce the hand into the vagina, then to pass the fingers to the edge of the placenta, and carrying them on between it and the os uteri, to sweep the hand round its whole circumference, so as completely to detach the placental mass, care being taken to avoid rupturing the membranes." He now resorts to galvanism, in order to secure uterine contraction, and the subsequent management of the case must be conducted on ordinary principles, such as supporting the woman by stimulants, nutritious articles of diet, and transfusion.

Although Dr. Radford has confined his remarks to the treatment of those cases of hæmorrhage which are attended with exhaustion before delivery, he believes that there are others to which galvanism is equally applicable; as for instance those of accidental hæmorrhage before delivery, where artificial rupture of the membranes has not succeeded in arresting the flux, and some of the hæmorrhages of the early months of pregnancy; wherever, in fact, atony of the uterus is the principal feature of the accident.

The apparatus employed by the author "consists of a battery in a small jar, and a helix with conductors. For the sake of convenience, the latter are connected with the helix by means of long wires, covered with an isolating material. The strength of the shock is regulated by a small contrivance situated on the stand of the helix, by means of which it can be either diminished or increased. One of the conductors, which is applied externally, has a hollow wooden handle, through which passes the wire before alluded to, in order to join a brass stem terminating at its extremity in a ball. The other conductor, which is contrived by himself, consists of a strong brass stem, seven inches long, curved to suit the vagina, and covered with a non-conducting material, having a small screw at its distal extremity for attaching to it a silvered ball; at its other extremity it is received within an ebony handle, which is hollow, and through which passes a strong brass wire, looped at the

end, and connected with the long wires before alluded to. This wire is kept disconnected from the brass stem by means of a spiral spring concealed within the ebony handle. The loop is covered with silk, and is intended for the thumb of the operator, when he is bringing the wire into connection with the stem.

"When the remedy is applied, the brass ball of the vaginal conductor is to be passed up to the os uteri, and moved about at intervals on to various parts of this organ. At the same time the other conductor must be applied to the abdominal parietes over the fundus uteri. Shocks may also be passed transversely through the uterus by simultaneously applying the conductor on each side of the belly.

"The application should be used at intervals, so as to approximate in its effects as nearly as possible to the natural pains. It may be continued until it meets the exigencies of the case."

We recommend a perusal of the above lecture to all practitioners engaged in midwifery.

MEDICAL GAZETTE.

Friday, January 10, 1845.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medice* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

HOW IS QUACKERY TO BE REMEDIED?

THE prevailing cry at present is, Down with quackery. A large number of medical men throughout the country are loudly calling out, like the silver-smiths of Ephesus, "this our craft is in danger," unless Government step in and prevent all unqualified persons from practising physic or surgery. They seem impressed with a belief that no act of the Legislature will meliorate the condition of the profession, except this end be attained; and that it can only be attained by penal measures of the most stringent description. Now, as far as overt quackery is concerned,

we entertain a directly opposite opinion. No Government, whether despotic or democratic, can put it down by any such means. It forms a sort of fungous excrescence upon the *body medical*, which, the more it is interfered with the ranker it becomes. There is a principle in human nature favourable to its growth. The patient stricken with incurable disease, like a drowning man, catches at every twig, and lends a willing ear to the boastful pretensions of any mountebank who proffers relief. Love of life in the one, and of money in the other, says Sir Richard Steele, creates a good correspondence between them.

By way of illustration, let us consider what was the effect of imposing legal restraints in ecclesiastical matters, with the view of repressing what the ruling party looked upon as irregular practice there? Did not the rigorous methods taken to destroy obnoxious separatists, as the nonconformists were styled at the beginning of the 17th century, serve only to extend and strengthen their cause? Again, about the middle of the same century, were not the quakers oppressed with fines, imprisonment, and spoiling of goods; and yet, undismayed by these severities, did they not rapidly increase and spread themselves over the kingdom? Now we are convinced, although the analogy is somewhat strained, that the very same thing will hold good with respect to empiricism in the healing art. In proportion as attention is called to it by persecution, so will it flourish.

What really can the state achieve in such cases by legal coercion, when chartered bodies like the College of Physicians and the Society of Apothecaries, invested with ample powers for the protection of their vital interests, have signally failed in turning them to good account. Indeed, as we are told

in an elaborate article on Medical Reform, in the last number of the Edinburgh Review, "the experience of the London College of Physicians tends to establish three principles in medical legislation : first, that quackery is not to be put down by direct penal enactments ; secondly, that the power of inflicting direct penalties for irregular practice is apt to be perverted and applied against nominal or technical irregularity merely, instead of real ignorance ; and thirdly, that uncontrolled powers cannot be safely entrusted even to the most enlightened medical corporations" : p. 243.

But it may be asked, is there no means of abating this evil, of preventing the illiterate and ignorant from trespassing on the domain of the regular professional man ? Assuredly there is, and it ought to be afforded. We are persuaded that if the restrictive clause in the draft of the bill now before parliament be somewhat extended and more distinctly defined, it will answer every purpose, and no party will have any right to complain. By that clause it is enacted that whoever pretends to be a registered practitioner when he is not so, shall be deemed guilty of a misdemeanour, and punished by fine and imprisonment ; and we understand it is farther intended that no unregistered person shall be allowed to assume any one of the names or titles by which registered practitioners are distinguished. Now we conceive that this will exercise so far a most salutary influence. It will enable the public to discriminate whom they may entrust with their health and lives, and whom they may no trust, save at their own peril.

An esteemed contemporary has proposed "limiting the right of treating diseases in *private houses*, as well as in public institutions, to registered practitioners." We do not see in the present

state of society how this desirable object could be well accomplished.

One thing, however, is certain, namely, that some means must be put in force for restraining the chemist and druggist from officiating in the treatment of disease, and in reference to this we would crave an extension of the above clause. We believe that among the underlings of that body there is many "a boastful pretender to medical skill which he does not possess," ready upon all occasions to volunteer his services, whereby "every now and then the patient may lose his sight from an ill-treated ophthalmia, or his life from an inflammation of his lungs neglected in the beginning*." Common justice demands that the poor should not be left at the mercy of persons of this stamp, or that the qualified practitioner should be tricked out of his fair emolument by such unlawful courses. Were the chemist and druggist strictly confined to the duties of his calling, the preparing, compounding, and dispensing of physic, as we know to be the wish of the leading members of the Pharmaceutical Society, and as is the case in France and Germany, the mischief would work its own cure. There has been, and always will be, a certain amount of counter-practice, but this is shunned as much as possible by all respectable venders of drugs, and is not, we understand, upon the increase.

We need not impress upon our professional brethren that in the redress of the above grievance a vast deal depends upon themselves. They must eschew every semblance of quackery and mercenary dealing. Let it be no longer imputed to them as a scandal that "physic is ordered rather to make a long bill than a quick cure." Surely the man who issues from his arsenal twelve gross of draughts in one day, is just as reprehensible as the homœo-

* Quarterly Review, December 1844, p. 11.

pathic doctor who doles out his globules of sugar of milk by infinitesimal instalments. We strongly suspect that the wholesale system of drugging formerly pursued in England, has tended most materially to foster the evil in question; for many a one who had little or no faith in the abilities of a quack, applied to him simply because he seemed willing to sell health at a reasonable profit.

ABSTRACT OF THE MOST MATERIAL FACTS
OF THE
CONTROVERSY BETWEEN DR. LEE,
OF LONDON, AND DR. PATERSON,
OF LEITH.

To the Editor of the Medical Gazette.

SIR,

HAD the late controversy between Dr. Robert Lee and Dr. Paterson, of Leith, involved nothing more important than the honour of the parties concerned, it might perhaps have been unnecessary to trouble you and your readers further with the subject. But to me it seems that the reputation of our profession with the public, and the most sacred interests of society, are at stake. There are some over-zealous members of the medical body, who would make questions of physic matters of certainty, who would lay down laws of unerring and unexceptionable application. Such persons are generally found, as in the present instance, to pin their faith on some fact, circumstance, or symptom, to which they attach a particular meaning. This is all very harmless, when the erroneous opinion in question has no more important application than the undue vogue of a trifling remedy. It may then fairly await the correcting hand of time, the failure of its bloated promises and the progress of science, which will full surely set aside crude and trifling fancies. But an ill-digested hypothesis assumes a very different degree of importance, when the honour of women, the cause of justice, and the interests of mankind, hang upon its decision. It becomes necessary then to check the overweening confidence of such zealots in the absolute truth of their crotchety doctrines, that our great and noble art of medicine may not be held up to the derision and indignation of mankind, that judicial errors of the worst description may not be perpetrated, and that the land may not be filled with hapless families, bewailing the lost reputation of mothers sacrificed to the ill established

medical opinion of what is a true corpus luteum and what a false. These feelings irresistibly crowded upon me as I read the controversy between Dr. Lee and Dr. Paterson, and, under their influence, I made a short abstract of the whole matter, which seemed to me necessary, as the principal facts are by no means clearly put by the parties concerned. I send it to you in the hope that it may appear of sufficient interest to deserve a place in your next number.

A PHYSICIAN.

London, Jan. 6th, 1845.

A poor woman was murdered by her husband at Edinburgh, in the year 1840. Soon afterwards, Dr. Paterson published in the Edinburgh Medical and Surgical Journal, an account of the circumstances, and stated that he had found a true corpus luteum, the result of impregnation, in the ovary, and a deciduous membrane in the womb.

Based on these facts, Dr. Paterson drew the conclusion that this poor woman was an adulteress.

Dr. Lee, commenting on Dr. Paterson's statement, denied strongly the fact, or the opinion that the appearance in the ovary was a true corpus luteum, insisting that it was only an extravasation of blood, and that membranes like the decidua were often found in the uterus without impregnation.

In the month of May last, Dr. Lee received a letter from Dr. Bowman, of Monkwearmouth, requesting his opinion on an appearance in the ovary of a female, whose case had given rise to a divided opinion in the country.

Dr. Lee wrote to Dr. Bowman a letter now in the possession of Dr. Paterson. In this letter, he believes he states what was really the truth, that he was, at the moment, deeply and anxiously engaged, and unable to give the time necessary for such an examination; but that he would send the preparation to Mr. Wharton Jones, who would submit it to the microscope, and his opinion should determine the point. This letter has, for reasons best known to Dr. Paterson, been suppressed—indeed, its existence was for a time denied.

Mr. Wharton Jones pronounced the appearance in question to be a real corpus luteum, and this opinion was transmitted by Dr. Lee to Dr. Bowman.

Dr. Paterson, of Leith, then wrote to Dr. Lee that the preparation submitted to him was taken from the body of the woman above mentioned, and contained the identical change of structure on which Dr. Paterson had pronounced the judicial opinion impugned by Dr. Lee. Dr. Paterson then called upon Dr. Lee to retract his severe strictures.

This Dr. Lee refused to do, on these grounds: he admits he has been wrong in

agreeing to submit so important a matter to the decision of the microscope alone, that he did so without sufficient thought, and has been guilty of a great error in doing so. But he did so in the faith that he was truly and honourably dealt with, which his antagonists avow somewhat boldly not to have been the case; he did so in the conviction that the preparation was what it pretended to be—a recent one—and without a suspicion that it had lain four years, or even four weeks, in spirits; he did so, moreover, in the conviction that the reference was honestly made to him from Monkwearmouth of a point in dispute at that place or in its neighbourhood. Of course, this was an intentional deceit. But it is only fair to state, as part of Dr. Lee's case, that had he suspected the infamous trap laid for him, he would not have delegated to any one the decision of such a point; neither he nor any one could have thought of submitting to the microscope a preparation steeped in spirits for such a length of time. When he wrote to Dr. Bowman, he seemed chiefly actuated by a desire to rid himself of a laborious task, and, at the same time, promote the wishes of a professional brother, who approached him with fawning and artifice.

It is difficult to conceive what the plotters of such a scheme as this could expect to gain by it. They might, indeed, had Dr. Lee been weak in conduct, have made him abide by the decision of the microscope, but would the fact have been altered, would the sacrifice of Dr. Lee's professional name to a dishonest trick like this have affected in the smallest degree the scientific point in question?

Dr. Lee seems justified in his resolution not to permit the solution of this question to rest upon the investigation of Mr. Wharton Jones, by the avowal made by this gentleman in the report (carefully omitted by Dr. Paterson) that the appearances presented by the microscope do not manifest any difference between a corpus luteum the result of impregnation and one that is not.

Dr. Lee, moreover, does not appear by the narrative to have any other reason for believing that the preparation submitted to him and Mr. Wharton Jones is the same taken from the body of the woman already mentioned, except the assurance of Dr. Paterson; and really after the appearance which this gentleman voluntarily makes, and his detected mistatements, this would seem hardly sufficient. It is rendered still more questionable by the fact, that the anatomical characters of the body in the ovary, as now given by Wharton Jones, are at great variance with those set down by Dr.

Paterson four years ago; and that, in the preparation, there was found no deciduous membrane in the womb, though such an appearance is particularly described by Dr. Paterson.

My abstract would not be complete did I not here state, that Professor Owen, and other eminent anatomists, have confirmed Dr. Lee's opinion, that the appearance described and delineated in a coloured engraving by Dr. Paterson, was nothing but a clot of blood.

Add to all this, the unexplained falsehood about the letter. Having been trapped into writing to Dr. Bowman as a friend, Dr. Lee did not keep copies of his letters. But his recollection of having written another letter besides those the copies of which were supplied to him by Dr. Paterson, was distinct and positive. In answer to his repeated demands of that suppressed letter, its existence is again and again denied. At last he is insultingly told he is attempting to impose. After all this deceit, however, the fact of the existence of this letter in the hands of Dr. Paterson is extorted, but the admission is made without apology of any kind, and a copy of it is still withheld. To cover this disgrace, a new fraud even is attempted, and Dr. Lee is represented as having asked for a fourth letter. To complete the history, it appears that the editor of the Medical and Surgical Journal of Edinburgh printed the letters from copies, and not from the originals.

Verily, we think Dr. Lee may leave it to all men to determine where lies the fraud and the dishonour. But we trust we have attained our chief object, of destroying the pretension to determine so important a question as that of the pregnancy of females by so insufficient a test.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

[We inserted, two numbers back, an explanation of certain observations made in the course of an article which appeared during the month of November, and in which the state of the Royal College of Surgeons of Edinburgh was incidentally noticed. We have just received the following letter from the Secretary of the College, which we do not hesitate to print.—Ed. Gaz.]

To the Editor of the Medical Gazette.

SIR,

I BEG to refer you to the terms of my letter of the 17th December, containing an extract from your number of the 8th November, of which it was my duty, as Secretary of this College, to complain.

In that extract you had asserted that the College of Surgeons is at the present time "*literally bankrupt*," and that it was your belief that they had "had a proposal made to them by one of their leading members to sell their Museum to find ways and means to meet current expenses." Your number of the 27th December, now before me, contains a paragraph which amounts merely to a correction of the rumour as to the Museum. Now the averment of actual bankruptcy made by you upon your own authority was the only really important part of the statement; for you must be sensible that no proposition by an individual member of the College in regard to the Museum, however extravagant in itself, could have deserved a serious refutation by me unless from its bearing upon the other assertion. That assertion, I again repeat, is untrue, and has not the shadow of truth; and I therefore again request, as an act of reparation for the injury thereby done to the College, that you will contradict it in your next publication, and that you will at the same time insert in it this letter.—I am, sir,

Your obedient servant,

JOHN SCOTT, *Sec.*

Royal College of Surgeons, Edinburgh.

4, Queen Street, Edinburgh,
Jan. 6, 1845.

BRITISH MEDICAL ASSOCIATION.

To the Editor of the Medical Gazette.

SIR,

I AM directed to forward for your information the following communication which has been sent by the Society of Apothecaries to the President of this Association.

I am, sir,

Your obedient servant,

C. H. ROGERS HARRISON,

Honorary Secretary.

British Medical Association,
Exeter Hall, Jan. 5, 1845.

To Dr. Webster, Dulwich.

SIR,

I AM desired to inform you that the Court of Assistants of this Society has unanimously confirmed a report of the Act of Parliament Committee, communicating the statement made to the deputation from the Medical Association who honoured the Society with an interview on the 10th inst., and recommending that the Committee, should be authorized to take such steps as might be deemed expedient for approaching the Crown on the subject of a Charter of Incorporation of the General Practitioners, and I am further desired to inform you that the Committee are prepared to act without loss of time, on the instructions which they have

received from the Court of Assistants, to carry out the recommendation of their report.

I am, sir,

Your obedient servant,

ROBERT B. UPTON,

Clerk to the Society.

Apothecaries' Hall, Dec. 26, 1844.

RESEARCHES ON THE WOUNDS OF BLOOD-VESSELS.

By M. AMUSSAT.

1. WHEN the two carotids are cut at one and the same time in a large transverse wound of the neck, death is not instantaneous, as is commonly supposed; the hemorrhage lasts several minutes, during which the animal preserves all its faculties.

2. The carotid arteries do not remain gaping after their division, as would be supposed; and notwithstanding the volume of these vessels, obturator clots form as after the division of a single carotid.

In examining the plates which represent the arteries of dogs, and especially the carotid arteries of oxen killed after the Jewish fashion (bled to death without being knocked on the head) the organization of the clot is exactly what is indicated in the author's former memoir.

3. The simultaneous section, or that performed at a short interval, of the nerves of the eighth pair and of the carotid arteries in the middle of the neck, exercises no influence upon the formation of spontaneous clots or obturator plugs of carotid arteries cut completely across.

4. The spontaneous clot formed at the extremities of the divided arteries is composed of two clots; one exterior, already described in the former memoir; the other interior, which is nothing else than an organized coagulum absolutely resembling that formed by artificial means; as obturation, compression, cauterization, ligature, or torsion.

5. The spontaneous obturator clot is often very difficult to recognize. In order to find it, it is necessary to call to mind the anatomical disposition of the divided artery and to observe the pulsations at the extremity of the vessel. Besides, by the touch may be distinguished the small sanguineous mass which forms the clot.

6. It is therefore obvious that it is always by a clot or obturator plug that hemorrhage is spontaneously arrested, whether the animal dies or recovers; thus the doctrine of a *spontaneous clot external and internal* opposing the issue of blood from arteries completely divided, is the only true one; and contrary to the opinion of Jones and Bécclard, the artery may itself suffice."—*Comptes Rendus*, Dec. 1844.

ON THE
NUMERICAL RELATION OF THE
MEDICAL PROFESSION
TO THE
POPULATION OF GREAT BRITAIN.

ANNUAL RATE OF MORTALITY—THE NUMBER REQUIRED TO SUPPLY THE LOSSES BY DEATH.—REMARKS ON THE PROBABLE RESULTS OF THROWING OPEN THE PROFESSION TO UNLICENSED PERSONS.

By ALFRED S. TAYLOR,

Member of the Royal College of Surgeons in London (1830), and Lecturer on Medical Jurisprudence and Chemistry in Guy's Hospital.

THE subjoined tables have been drawn up from the Report of the Commissioners of the Census for 1841. An abstract of this Report, so far as it relates to the "Occupations of the People," has been published in the Companion to the Almanack for 1845, and from this I have derived the numbers of persons actually engaged in the exercise of the medical profession at the time of the late census. The other facts are a simple matter of calculation. It is necessary to observe that under the head of "medical profession" are comprised 1476 physicians, and 18,658 surgeons, apothecaries, medical students, cuppers, and dentists. Unlike the other professions, the medical is entered as of both sexes, comprising midwives, of whom 676 were returned for England, and 641 for Scotland. All professional persons, both above and under 20 years of age, are equally included.

No such returns as these have, I believe, before been made in this country; and although from the indiscriminate mixture of licensed and unlicensed persons, they cannot, in their present state, be regarded as perfect, yet they may serve to throw some light on the proportion of the members of the medical profession to the mixed population in counties,—in agricultural and manufac-

turing districts, and in different parts of Great Britain. From them, we may also calculate, according to the usual rate of mortality, the annual loss by death, and the average number required to replace those who are thus removed.

It will be seen from this table that the proportional numbers of the profession to the population are much greater in Middlesex and Surrey than in other counties, being 1 to 366 in the former, and 1 to 517 in the latter. This is obviously owing to the vast number of practitioners collected in and around the metropolis, forming nearly one-fourth of the whole aggregate of England, Wales, and Scotland. In the city of York, the proportion is large, although probably not larger than would be found to exist in all populous towns and cities. In the construction of the tables, no distinctions of this kind could be made; but it is probable that while the profession would average about 1 in 500 in towns, it would not exceed 1 in 1100 in rural districts. In looking to the counties, Kent appears to contain the largest number of practitioners, being 1 in 771 of the population, a proportion which, as we shall see hereafter, is much greater than the average for all the counties of England and Wales.

On the other hand, those counties which have the smallest number of members of the profession are,—1, the West Riding of York, which, with a population of considerably upwards of a million of inhabitants, has only 1 medical practitioner to 1291 persons; 2, Wilts, which with a population of upwards of a quarter of a million, has 1 to 1299 persons; 3, the small county of Rutland, which has 1 to 1330 persons, the population being, exclusive of the profession, only 21,286; 4, the county of Stafford, which, with a population of more than half a million of inhabitants, has only 1 medical practitioner to 1314 inhabitants; 5, Cornwall, which has 1 to 1364,—facts the more remarkable, since a large proportion of the labouring per-

sons in these counties are engaged in occupations liable to lead to accidents ; 6, the county which is the least supplied is Buckingham, for here we find only 1 medical practitioner to 1498 persons. This may be regarded as an agricultural county. It has rather more than half of the number of practitioners which it should have, according to the present average of England and Wales. (See top of next page.)

It will be seen from this table, that the counties of Wales are more thinly supplied

with the medical profession than those of England,—the minimum proportional number exists in Pembroke, being 1 to 1833 ; the maximum number in Flintshire, being 1 to 879 of the population. It is remarkable that the populous county of Glamorgan, occupied as it is by a mining population, should have only 1 medical practitioner to 1295 inhabitants.

The British Islands have more than the average in proportion to the population, being 1 to 677 inhabitants.

Wigtown	37	39,158	1058

On examining the table for Scotland, it is impossible to avoid being struck with the extreme differences in the proportion of the profession in different counties. Thus, while in Edinburgh there is one medical practitioner to 250 persons, in the adjoining shire of Haddington there is only 1 to 7177 persons. The vicinity of Haddington to Edinburgh at once accounts for the difference. It seems extraordinary that there should be only five medical practitioners in Haddington, to a population of nearly 36,000 persons; but such is the return. The extremes in these two counties must, therefore, be considered to compensate each other, and in this view the proportion of the profession in Edinburgh should be diminished, and that of Haddington increased.

Among the other Scottish shires, in which the profession is most numerously found, are,—1, Bute, where the proportion is one in 513, the population not reaching 16,000; 2, Aberdeen, where the proportion is, with a large population, 1 in 563; and 3, Banff, where, with a comparatively small population, it reaches 1 in 604,—a proportion considerably above the average of Great Britain.

After Haddington, the smallest proportional number of medical practitioners are found in Forfar, where, with a large population, there is only one to 2506 inhabitants; 2nd, in the large but thinly populated county of Sutherland, where it is only 1 to 2252 inhabitants; and, 3d, Caithness, where it reaches 1 to 2184 inhabitants. In the large county of Lanark, containing nearly half a million of inhabitants, the profession averages 1 to 807 persons. Orkney and Shetland may be considered as very fairly provided, the number of medical practitioners in these remote islands averaging 1 in about 1000 inhabitants.

Notwithstanding the wide differences thus existing in the Scottish shires, it must be obvious at a glance that, on the whole, the profession is much larger to the population in Scotland, than it is in England and Wales. This will, perhaps, be rendered more evident by the following results.

According to the Census of 1841, the total number of persons thus engaged in medical practice in England and Wales amounted to 18,436; and in Scotland, at the same time, to 3,568. Thus:—

		Proportion to Population.	
In England and Wales, (the Channel Islands excluded)	18436	= 1 : 856
In Scotland	3568	= 1 : 734
		<hr/>	
		22004	
Deduct Midwives in England	676	
„ „ Scotland	641	= 1317
		<hr/>	
Total in Great Britain.		20,687	

This would leave a total of 20,687 practitioners of medicine in Great Britain; but another deduction should be made from this total, of those who are included under the head of medical students, cuppers, and dentists. There are no data to enable us to make this deduction with correctness, since the object of ascertaining the “occupations of the people” was rather of a political than a professional nature. It would, however, be easy to acquire at another time a statement from each medical practitioner as to whether he held a diploma, and of what College; and it would be more satisfactory if those members of the “medical profession” who are of the female sex, were altogether excepted from the return!

The aggregate above given does not exactly correspond with that stated at the commencement of this paper, not even on adding

the numbers of the medical profession in the Channel islands. The difference, however, is not very material.

From these tables, it would appear that the numbers of the medical profession practising in Great Britain are often considerably overrated. It appears to me impossible to estimate medical students, cuppers, and dentists, engaged in practice, at less than 2000, and this would leave, according to the aggregate returns of the counties, only about 18,000 members licensed to practise in England, Wales, and Scotland. Hence, instead of the average being as it is above presented, about 1 to 800 of the population, it would not probably be more than 1 licensed practitioner to 1000 persons.

To what extent the medical exceeds the legal profession in numbers will be evident from the subjoined table.

Total Numbers.	England.	Wales.	Scotland.	Channel Islands.
Legal Profession	13759	396	3185	114
Medical Profession	17745	691	3568	183

There can be no doubt that for many years past, the numbers entering the medical profession have greatly exceeded the

wants of the community. In no other way can we account for the strong competition which exists for all public offices and ap-

pointments, however insignificant, and the very low and insufficient rates at which remuneration is made to the medical officers of Poor Law Unions and public institutions generally. It is impossible to understand why men belonging to a liberal profession should compete with each other for offices, which, while they entail a far heavier amount of labour and responsibility, yield often less remuneration than clerkships to Quarter Sessions, were it not that the medical profession is greatly overcrowded. Other facts well known to professional men, which need not here be alluded to, also bear out this view. Allowing that the licensed practitioners now form the one-thousandth part of the community, it is not too much to say that a proportion of *one professional person to twelve hundred* of the community would be ample, and that any number greater than this must tend to create that unfortunate state of things which is at present witnessed. This estimate is, in the absence of more accurate calculations, founded on the tables appended to this paper. At any rate the present distressed state of the profession, and the decline of all the medical schools, metropolitan and provincial, render it probable that the proportion above given as sufficient for the community cannot be far from the truth. Admitting this, we shall see on referring to the statistical table of England, that no less than 32 counties and districts out of 43 are overstocked; in Wales there are only three counties out of 12 in this predicament, while in Scotland, out of 32 shires, there are 25 which have a larger proportion than that assigned above as the probable necessary average.

The occupations of a population, and the relative healthiness of districts, with other circumstances, may render it necessary to raise or diminish the average numbers of the profession. Thus, a manufacturing population exposed to accidents from machinery, and living in densely crowded places, will require a larger number of professional men, than one living in a rural district and given entirely to agricultural pursuits. There is a striking difference in this respect between the counties of Wales and England. It might be interesting to connect the comparative healthiness or unhealthiness of districts with the proportion of professional men to the mixed population; but it would be foreign to my present purpose to enter into a discussion of this kind. Although the Registration act has done much, we are as yet scarcely provided with the elements necessary for such calculations. Many interesting facts have, however, been brought to light by the researches of Mr. Farr, on the number of deaths by *violence* in England and Wales, and these are well deserving of the attention of medical practitioners. In

1838, the violent deaths in the whole population amounted to 12,055; in 1839, they amounted to 11,980—the average falls little short of 12,000 per annum. It has been ascertained that in the northern counties 16 persons in 1000 die violent deaths annually; in Staffordshire, Warwickshire, and the other western counties, 14; in Lancashire and Cheshire, 13; in Cornwall and the other south-western counties, 11; in the metropolis, 8; and in Essex, Suffolk, and Norfolk, 7. The accidents producing violent deaths are least common in the agricultural districts, more frequent in cities and manufacturing places, and most fatal in the mining parts of the country.

There is one subject which remains to be noticed in connection with these tables, viz. the number of professional persons annually removed by death, and the number required to replace them. Admitting that the present number of licensed medical practitioners averages 1 to 1000 of the community, this would give to Great Britain about 18,000. From the reports under the Registration act, it would appear that the average annual rate of mortality for England and Wales amounts to about 1 in 45 for the whole population. It is true that the rate of mortality is different at different ages; and that it is proportionally greater in persons under puberty and in advanced age than in the intermediate period. The number of deaths between 20 and 60 is found to vary but little according to age. If, therefore, we assume that the same law respecting the average mortality holds with regard to the medical profession as with the non-professional public, we may take 45 as the divisor, and this would give an annual loss to the profession of 400 of its members. The number would be rather less if 1 in 45 were considered to be too high a rate of mortality for persons generally above the age of 20 years. Thus, then, the continued annual addition of about 400 members, and a slight yearly increase in proportion to the increase of population, would be required to keep the profession in its present state. Some allowance must be made for those who annually enter the army, and many who emigrate to the colonies. Taking these at the maximum at one half of the number required for the restoration of the annual losses in Great Britain, it would appear, in a time of peace, that the yearly addition of about 600 members to the profession would maintain it in the state in which it now is. Admitting, however, that 15,000 practitioners are sufficient for Great Britain, similar calculations would lead to the result that the yearly additions to the profession should not exceed 500 members, including those required for Great Britain and its colonies. But it is notorious that the number of new members annually ad-

mitted in England and Scotland has been for many years past much larger than this. From the report of the Apothecaries' Society, it appears that during the last 28 years the diploma has been granted upon an average to 360 persons annually; and although many of these at the same time received the diploma of the College of Surgeons, yet a certain annual number, including all who enter the army and navy, and who receive the diploma of the College alone, must be added. To this number we must likewise add those who are admitted by the Royal College of Physicians in England, and by the Universities and Colleges in Scotland*. It will, I think, be apparent from a consideration of the various matters here brought forward,—1, that many more medical men are now licensed to practise than the wants of the public demand; and 2, that with the number of new practitioners actually required, the present number of medical schools in London, the Provinces, and in Scotland, could not possibly be maintained with any degree of respectability or efficiency.

The number of complete schools of medicine, independently of those institutions, either private or public, where distinct courses of lectures on one or more medical subjects are given, amounted at the commencement of the present session (Oct. 1844) to *eleven* in London, and to *seven* in the provinces. This statement is taken from the advertisements which appeared at that time in the medical journals. If the whole number of those new members now annually required to keep the profession in its present state, and to supply the army and navy, were equally distributed among these medical schools, it would give only on an average 35 new members per annum to each school: if the actual requirements of the community were regarded, according to the foregoing considerations, the average would be only *twenty-five* new members per annum! In this calculation the numerous medical schools and colleges of Scotland are omitted. It will be easily understood, that by the necessary introduction of them, the average number of pupils to each would sink considerably lower. Thus, then, the present number of schools and colleges can only be maintained by a forced and undue supply of professional men to the public. The evil is in some respects righting itself; for the number of those now attending the schools is almost universally diminished, and appears to be annually decreasing.

The tables heretofore appended give us, for the first time, an idea, if not absolutely,

at least approximately correct, of the numerical relation of the profession to the public. Events passing around us, and within the knowledge of almost every individual, show that this numerical relation is at present too great, *i. e.* that there are more professional men than the public require. The application of the common law of mortality in this country, to the ascertained numbers of professional persons, enables us to determine approximately the number required annually to replace those who die; and this number admits of comparison with the number of those annually licensed to practise. I am well aware of the fallacies to which figures are liable, but I do not claim for the conclusions which I have drawn more consideration than the tables warrant. It is scarcely possible to enter upon such researches without being enticed into speculation; but as all the premises upon which the conclusions are founded are fully detailed, the reader will be able to judge for himself.

When the profession is overstocked, and so many more members are annually licensed than can find any profitable occupation, it is impossible to understand why men, who ought to know its actual state, should advise that all restrictions on medical practice be set aside. Its members are even now too numerous for the community, and yet it is proposed to add more!—the addition to consist, in the words of the minister of State who introduced the Medical Reform Bill, of “any men whatever, who possessed skill and knowledge to practise medicine.” Strictly speaking, this implies any men whatever, who *assume* that they possess skill and knowledge to practise medicine,—a very large class, especially in country districts! The man who devotes many years to the actual study of his profession, is thus placed on a level with him who *assumes* that he possesses medical knowledge without having devoted any time to the acquisition of it. Again, the competent and industrious candidate who receives his diploma from the examining boards appointed under the Bill, is virtually placed on the same level with the ignorant and idle candidate, who is rejected by these boards: for the latter, notwithstanding his incompetency, *thus proved by his rejection*, may retire into a country district and practise to the injury of the competent man as well as the public. Is it to be supposed that, should such a measure receive the sanction of the legislature, the members of the medical profession, pauperized as it is in many of the rural districts of England, will preserve only the proportion to the population, and to its increase at the census of 1851, which it had in 1841? It appears to me certainly not:—there will be few counties in which the proportion will not be at least doubled, and

* A writer in the last number of the Quarterly Review estimates that from the seventeen licensing bodies now in existence, there are probably from 800 to 1000 physicians, surgeons, and apothecaries, who annually receive diplomas!

probably tripled; and instead of 1 to 1000 of the population, a proportion even greater than is required, we shall find the new practitioners, including the licensed and unlicensed, to form probably 1 to 500. If any one doubts the correctness of this statement, let him turn to the statistical tables of the "occupations of the people," and observe the number of persons who are classed as the unoccupied. The census of 1841 demonstrates that in England, Wales and Scotland, of the male sex only, and above 20 years of age, there were without any occupation 274,482. It is not to be supposed, however, that the new practitioners in medicine will be derived from this class alone. Among the occupied millions there are numbers so dissatisfied with their condition, as to be ready to change it for what may have only the appearance of being more profitable employment. They will be put to no expense by preparatory study or the purchase of diplomas. In order to give them a title to practise, they will merely have to *assume* that "*they possess sufficient skill and knowledge to practise medicine.*" The condition of these persons cannot be made worse by such a change, while that of the general practitioner must inevitably be, under such legalized competition, a lower degree of pauperization. These pretenders care not about appointments to public offices, the registration of their names with Boards of Health, the serving on juries, or the power of recovering debts by civil action. What they will look to will be the immediate means of living; and these they will obtain to the inevitable loss of the general practitioner, and to the injury of the public. Those who require medical advice, it is said, may consult a printed register to determine who is and who is not a licensed practitioner; but the very principle of the new measure is, to allow the public to employ either one or the other. The deplorable state of ignorance existing in rural populations especially, does not appear to be have been here taken into consideration. As some test of this, it may be remarked, that nearly one-half of all those who are married of both sexes are unable to write their names! In Monmouthshire and Wales these amount to 60 per cent. of the married! This has been proved by the returns under the Registration act: and yet it is assumed, that the public have it in their power to consult a printed register before they call in a medical man! One fact like this appears to me sufficient to show that a large portion of the public of England and Wales are not fitted to distinguish the incompetent from the competent practitioner.

[It is very true that some can read who are unable to write their names, but how many in England are there, married and un-

married, who are unable to read or write! Since the above was written, an article on the Medical Reform Bill has appeared in the Quarterly Review (December 1844). The writer observes that the Government "having taken the pains to point out to the public the proper course to be pursued" (*i. e.* consulting a printed register of licensed medical practitioners) "the safest way will be to leave it to the good sense of individuals to protect themselves." How many, out of the total population of Great Britain, possess that amount of "*good sense*" requisite for self-protection (for some kind of "protection" against the results of the proposed Reform Bill is clearly admitted to be necessary)—the writer does not stop to consider! He admits that the profession is at present "*overstocked*" with *licensed* practitioners, and yet he proposes to mitigate the evil by admitting *unlicensed* persons to practise.]

THE PERIODICAL MATURATION AND EXTRUSION OF OVA, INDEPENDENTLY OF COITUS, IN MAMMALIA AND MAN,
PROVED TO BE

THE
PRIMARY CONDITION TO THEIR
PROPAGATION.

By TH. L. W. BISCHOFF,

Professor of Medicine, and Director of the Physiological Institute at Giessen, &c. &c.

Translated by

HENRY SMITH, Esq. F.R.C.S. &c.

[Continued from p. 450.]

I THINK these experiments of my predecessors, together with my own, prove most decisively, that, even though the advance of the seminal fluid of the male through the fallopian tube up to the ovary, and its influence upon the ova, be prevented, yet, on the appearance of "the heat," and in the foregoing instances after reception of the male, all phenomena develop themselves in the ovaries and ova notwithstanding, just as in the perfectly normal condition. The ova mature, the Graafian vesicles swell and open, the corpora lutea form, the ova escape and reach the tube, and some of the phenomena of development even commence: as, however, the influence of the semen on the ova is prevented, that process does not advance farther, but the ova retrograde, dissolve, and abort. This last circumstance proves the whole succession of these phenomena to be altogether independent of coition, and to be solely and abstractedly founded on the progress of development of the ova.

Since I have proved the material contact of the seminal fluid with the ova, all thoughts of an "aura seminalis," of a resorption of the semen, or a still more mysterious influence of copulation, which previous observers declared to be demonstrated through these very same phenomena, are altogether out of question, and specially refuted in these particular instances, by the fact, that the ova, in consequence of the impediment to that material contact, were not endued with the capacity of development, and aborted. Had the extrusion of the ova, the development of the corpora lutea, &c. in these instances been conditionate on the semen and coition, the ova would have become fecundated also, and have advanced in their development. I consider, therefore, that notwithstanding the intereurrence of copulation, these experiments prove the independent progress of development of the ova.

Another observation which I was so fortunate as to make, shows, however, still more decidedly, how independent the maturation and extrusion of the ova are of coition.

With a view of ascertaining the point to which the seminal fluid penetrated in the bitch immediately in the act of coition, I obtained a strong and vigorous young one, which had never borne young. In order that I might know with perfect certainty when the first act of copulation took place, I kept the animal about me in my house, and watched it closely. At the beginning of June, 1843, I remarked that it was about to be "in heat," for the dogs began to follow her about, and a flow of blood took place from the vagina. On Friday, June 9th, however, the animal would on no account permit coitus to take place. It was therefore chained up, and kept strictly isolated until mid-day on Sunday. At three-quarters past 1 o'clock on that day I again brought a dog to her, and she then for the first time received the male.

Immediately afterwards I cut out the left uterus, ovary, and fallopian tube, closing the wound by suture. I first examined the uterus, and found it quite filled, even up to its extreme point, with lively-moving spermatozoa. My next object was to examine the tube, in order to see whether the semen had already penetrated into it also; as I was preparing this, and laying bare the

ovary, I saw to my surprise that the ova, which I had confidently expected to be yet in the Graafian vesicles, must have already left the ovary. I observed upon the ovary five small red openings, from one of which a small red mass grew forth, and saw that five Graafian vesicles had already opened there. The formation of the corpora lutea proceeding from the bottom and walls of the follicle was already far advanced; at the same time, however, they still contained a considerable cavity filled with limpid serum, but which no longer held an ovum. This afforded me additional evidence of the probability that such a condition of parts had led previous observers, who were unacquainted with the ovum itself, to think that the follicles were not as yet opened. I forthwith, however, became fully convinced that the opening had taken place, for I found the five ova close together, already advanced nearly two inches in the tube. The investigation of them yielded nothing novel. Their condition was altogether that which I have always seen in ova at the same stage, and as usual perfectly resembled the fully matured ovarian ova. On the other hand, I sought through the entire length of the tube, down to the ostium uterinum, for spermatozoa, without success; no such a thing was to be seen anywhere, and I devoted so much time and care to it, that I venture to assert positively that the seminal fluid had not yet penetrated into the fallopian tube.

On the following morning, at 10 o'clock, after 20 hours therefore, within which time, according to my previous observations, I had found that the semen can reach the ovary, I had the animal killed. The right ovary also exhibited five small openings, and five corpora lutea which were more advanced in their development than those of the opposite ovary, and in addition to these one very large unopened Graafian vesicle. This fallopian tube also contained five ova, which had advanced more than half way down it, and were several lines distant from each other. Three of them were perfectly normal in condition, and very like those of yesterday. Two, however, were distinctly abnormal and abortive, the zona being indistinct; the discus proligerus very incompletely developed; the yolk a small irregular mass of vitelline granules. I now also found spermatozoa

in the tube, some of which were still in motion, but they had only penetrated about three lines from the ostium uterinum. The tube did not contain any others throughout the rest of its extent, neither was there any trace of them around or upon the ova, so that the latter were certainly not yet fecundated.

I consider the foregoing investigation affords irrefutable proof that the ova, after having reached maturity, quit the ovary, and enter the fallopian tube, independently of all influence of copulation. That that act was not accomplished earlier than it was observed, may, from the measures adopted, be assumed as certain. That the ova might have been extruded during and in consequence of coition cannot at all be assumed, for the following reasons: in the first place, it is certain that that result does not always attend the act, as I have myself found the Graafian vesicles still closed in other bitches after they had received the male several times; and in the second place, it is not conceivable that the ova should have travelled a distance of two inches through the narrow fallopian tube in the short space of a quarter of an hour, whilst they require about eight days to traverse the remaining two to three inches of its length.

If, then, in this instance, the ova had actually left the ovary quite independently of copulation; if they must be considered to have reached the fallopian tube unfecundated, and to have remained so even after 20 hours; the next question is, how to reconcile this with my previous observations, in which I found the Graafian vesicles to be still closed in bitches 6, 18, 20 hours, after the first coitus, and the semen to have penetrated through the entire tube, even to the ovary.

The solution of the question is manifestly this; that the ova, when once matured, have a certain scope afforded both as to time and place for their fecundation. It depends, as it would seem, upon the individuality of the animal, and upon the opportunity, as to whether coitus be permitted and accomplished when the ova are still in the ovary, or when they are already extruded and have reached the fallopian tube. If the natural habits of the animal are not interfered with, and the opportunity for copulation be free, it appears that the sexual impulse manifests itself

before the ova are extruded. If coitus take place at that period, the semen has sufficient time to penetrate through the fallopian tube to the ovary, and this can take place in the dog in 20 hours, as my previous observations show. Other individual animals do not perhaps permit the act until a later period, or the opportunity fails, as in my case, because they are confined. The ova in such case are extruded notwithstanding; they may also still become fecundated by copulation taking place. I cannot determine with precision the range of time within which this is possible. As, however, bitches usually receive the male during eight days, and as the first more precise phenomenon of development of the ova, viz. the division of the yolk, commences in the lowest part of the fallopian tube, where they are to be found about the seventh and eighth day, this would seem to denote the limits of the capacity for fecundation (*befruchtungsfähigkeit*) of ova in the dog.

Since I gained an insight into these circumstances, my attention has been drawn to many results of my former experiments, which I had previously valued but slightly, and put a different interpretation upon. I was, as I have said before, prepossessed with the opinion that coition was the cause of the extrusion of the ova from the ovary. I therefore, like all my predecessors, always calculated from the first act of copulation. It happened accidentally that most of the animals which I made use of especially for this subject, had probably received the male before the ova were extruded. But I now find amongst my observations several instances in which I have remarked that, although the ova were found in the upper third of the tube, yet I saw spermatozoa only in its lower part. When once, however, I became acquainted with the fact that they might advance through the entire length of the tube, I thought I must have overlooked them in the upper portion in the above instances, perhaps because they were few in number, or I had not been sufficiently careful, and so on. But I am now convinced that such were instances in which the ova had passed out before coitus had taken place, and the seminal fluid had time to advance higher up into the tube. As a rule, I have also seen spermatozoa upon the ova in the

lower third of the tube only; more rarely in the parts above.

With respect to rabbits, (in which animal we cannot ascertain the presence of "the heat" so precisely as in the bitch,) when the doe receives the male, it seems that, in general, the ova are not extruded before the semen has had time to reach the ovary, for which, according to Barry and myself, nine or ten hours are required. In rabbits I have also always found spermatozoa upon the ova in the upper third of the tube; in them, also, the division of the yolk commences higher up in the tube, and probably, therefore, the scope for the capacity for fecundation of the ova is much shorter than in the dog.

It follows, then, from all the foregoing, that the mode of calculating the time of the extrusion of the ova, according to the first act of coition, and which has been hitherto universally the custom, is altogether uncertain, and can only, in a measure, approach to correctness (*annäherungsweise*.)

If then, according to this, it be certain that the ova may quit the ovary previous to coition, and enter the fallopian tube, so there can be no doubt but that this also takes place, when the act of coition is not effected at all, in which case, however, the ova of course abort. But very few data are to be found in previous authors which bear upon this point, and those naturally do not refer to the ovum, but to the Graafian vesicle and corpora lutea.

According to Kulemann (*Observat. quæd. circa negot. generationis*, p. 15, *Epicrisis*), in sheep which are "at heat," and which do not receive the male, or at least are not impregnated, no Graafian vesicles burst, and no corpora lutea form; at least he signifies that such only occurs as an exception.

Some experiments of Hausmann's unfortunately have not that demonstrative force which they would have possessed, had not the author slighted and denied the existence of the ovarian ovum. A bitch was "at heat" from the 29th of October until the 4th of November; coitus, however, was not permitted. On being killed at that date, the ovaries presented "Graafian vesicles, which had the appearance of corpora lutea, but exhibited no point of rupture, contained a limpid fluid but no ovum." (l. c. p. 73, exp. 25.) In another experiment (p. 87, exp. 41) a

sow was "at heat" on the 23d of June, but was not admitted to the boar. It was again "at heat" on the 9th of July, and would have received the male, but was not allowed. On the 12th coitus was permitted, and the animal was opened twenty minutes afterwards. The left ovary exhibited five mature Graafian vesicles, which had not burst, and six corpora lutea; the right also presented five mature vesicles, and three corpora lutea. Hausmann is of opinion that these corpora lutea owed their origin to the animal being "at heat" on the 23d of June.

With respect to the sheep, Hausmann says (l. c. p. 94):—"When the sheep does not receive the male, or is not impregnated, no Graafian vesicle bursts; yet it seems that, after frequently returning and unsatiated sexual desire, a Graafian vesicle does burst; after which an imperfectly developed corpus luteum forms." And in Exp. 56, p. 95, he found close to a corpus luteum, in the left ovary of a sheep which was then "at heat," and which had also copulated, another such body, less perfectly formed, which he himself considers to be a proof "that a Graafian vesicle may at times open without copulation." In exp. 58, p. 96, he farther states, that a corpus luteum was found on the ovary, near to a Graafian vesicle which had burst as the result of former coitus, "although the sheep had not received the male, but had several times been 'at heat.'"

[To be continued.]

CASE OF
PURPURA HÆMORRHAGICA,
PROBABLY ARISING FROM VARIOLOUS
CONTAGION.

By N. ADAMS, Esq. Banchory.
(For the London Medical Gazette).

J. S., a farmer, residing in a healthy district of the country, of a sound constitution and sober habits, about 25 years old, was engaged with his servants in cutting hay on the 3d of July, although he did not feel altogether well. Next day he was seized with nausea, general uneasiness, and other feelings, which he fancied might be the preliminary symptoms of an attack of small-pox, as he had been visited about three weeks previous by a sister, who had just recovered from the dis-

ease in its modified form. He was confirmed in this opinion next day by remarking some purple spots on his limbs: he took some opening medicine, and confined himself to bed in a well ventilated room.

I saw him for the first time on the 6th, at which time his face was puffly, especially his lips; his eyes deeply ecchymosed; the whole body rather swollen, but not so as to pit upon pressure; purple spots on his limbs, and large vibices on the neck, especially behind, all the lower part of the abdomen being covered with the same. His pulse was from 100 to 105, soft, full, and undulating; his tongue swollen, and a white rim running along his gums close to the teeth. The urine was of a dark yellow colour, but did not stain a piece of linen dipped in it. I bled him to the amount of ten ounces: the blood was sisy, but its coagulum loose. A solution of carbonate of potass with lemon-juice to be administered frequently, and *vj.* gr. of calomel, with *viii.* gr. of Hydrargyrum e. Creta, to be given next morning.

On the 7th, the purple blotches much extended, the lower part of the abdomen in particular being altogether of a dark purple colour, and the back thickly marbled with vibices and purple spots; stigmata on the arms and legs, but less marked than on the trunk; there had been considerable oozing of blood from the gums, and from the orifice made in the arm; the ecchymosis on his eye enlarged, and of a darker colour; impulse of the heart preternaturally great; throbbing of the arteries in the epigastrium and neck; no delirium; the urine darkish and turbid, deposited little sediment, but upon the application of heat some small coagula floated in the water; it still did not stain a piece of linen cloth; pulse 120, soft and feeble. The opening medicines having produced little effect, *vj.* grs. more of calomel, and $\frac{1}{2}$ oz. castor oil, were directed to be given. A draught, composed of lemon-peel and cream of tartar, to be administered *ad libitum*.

On the 8th, at noon, debility greatly increased; pulse 120, soft and feeble; the discharges from the bowels consisting principally of blood; the urine also reported to be bloody; slight oozing of blood from the gums and arm; the greater part of the back, and the whole of the abdomen, of a dark

red or livid colour; numerous stigmata and vibices on the other parts of the body; much jactitation and painful singultus, for which an opium pill, and a mixture with creasote, were ordered. Sago, seasoned with brandy, to be offered to him occasionally, and a strong solution of quinine to be had in readiness, to be given if the hiccup should settle. The gums to be washed with a solution of alum.

At 8 p.m., the weakness, and all the other bad symptoms, greatly aggravated; singultus had at first been stopped, but had returned of late; pulse at the arm scarce perceptible; alvine discharges like tar, those from the bladder of pure blood; the extremities losing their heat; great sinking, and muttering delirium, when left to himself; the colour of the body inclining to a dark green in many places; no appearance of vesicles, pustules, or papulæ; the eruption no where elevated above the surface; the eyelids, as well as the eyes themselves, were ecchymosed, and there were a few stigmata on the forehead, but no discolouration of the rest of the face. Brandy to be given *ad libitum*.

He died at 11 o'clock, p.m., that is to say, about five days after the commencement of the attack.

The disease described above is so uncommon in this part of the country, that although I have now been in pretty extensive practice in it for more than twenty-five years, I have never seen nor heard of any case exactly similar. I have met, indeed, with cases of *purpura hæmorrhagica*, but with none possessing the aggravated form of the present case, nor under circumstances rendering it so difficult to account for its spontaneous development in the system. In the absence, then, of any other imaginary cause to account for its generation in the present instance, I am inclined to believe it to have been connected with the contagion of small-pox, to which, as stated above, the patient had been exposed some weeks previous to the attack. What confirms me very much in this supposition is the similarity of the symptoms to those of a certain anomalous type of small-pox described by some of the older writers on that disease. For example, the following history of small-pox, related by Morton, bears a very striking resemblance to the case given above.

"*Historia* 39.—Martha Meade, an-

cilla, duodeviginti annos nata, die 24 Januarii, 1691, derepente cephalalgia et lumbagine immani corripiebatur.*** Die morbi tertio, mensis nimirum 27. Pharmacopola accersitus, post bolum nescio quem præcedenti nocte exhibitum, nulla efflorescentia in cute se prodente, audacter a vena cubiti ꝑxiv. vel xvi. sanguinis eduxit, qui cum impetu exsiliebat, atque nullotenus rheumatici sanguinis ad instar, concresebat, fibris penitus privatus. Die morbi quarto mane ego accersitus animadverti universam cutem efflorescentia continua et plana intense rubra, non scarlatina verum levi et plano crysipelate perfusam, maculis rubris minoribus, et nigris majoribus ubique per totum pectus sparsis. Urinam insuper ægra reddidit copiose et frequenter atque sinceri sanguinis ad instar intense rubrum. Dormiebat quidem quadantenus, verum oppressa et languida, atque pulsu tremulo et inordinato laborans, sese plurimum et pæne perpetua jactabat. * * * Sub finem quinti diei morbi, sanguine confertim a bronchiis exiliente suffocata periit labiis et manibus (uti in confluentibus variolis plerumque contingit), quadantenus ab inani naturæ nisu tumefactis. Cadavere inspecto cutem deprehendi (visu horrendum!) ubique planè nigricantem, proximo autem die colore cæruleo imbutam, qualem colorem etiam omnia lineæ sanguine conspurcata. Aquæ saponacæ primum immersa planè exhibebant, ac si fuissent arte tineta, quæ labes haud facile delabatur. Tantum valet hoc venenum, uti ad ἀκμήν pervenit in humanum ipsorum crasi imbutanda.”—*Hist. Variol. Var.* xi. 39.

In another place the same author observes:—“Malignæ enim hæmorrhagiæ a soluta sanguinis crasi et colantium glandularum eo spirituum languorem laxitate per διαπήδησιν ex intestinis, renibus, naribus, nonnunquam ex oculis, auribus, dentium alveolis, ‘qua porta datur’ equè ac è vasis uterinis instar loturæ carnum ubique perfusissimè scaturiunt, earumque prænunciæ sunt petechiæ frequentissimæ. Maculæ purpureæ et nigre quales peste correptis paulo ante obitum accidunt, quæ pari passu cum hæmorrhagiis cum quibus conjunguntur, numero et magnitudine, unaquaque pænè hora augentur vel diminuantur.”—*Ib.* viii.

Sydenham briefly mentions the complication of purpura with small-pox in the following passage:—“We must

confess that a bloody urine and purple spots, which are the most certain fore-runners of death, sometimes happen, when there is scarce any sign appearing of the small-pox, or but very few pustules coming out; and as these generally accompanied the pox that fluxed most, so now and then they invaded so very early, that they killed the patient before the full eruption.”—*Works translated by Pechy*, page 408; see *Greenhill's edit.* page 333.

The same symptoms, namely, purple spots and discharges of blood, are also mentioned at page 128 of the latter edition. Heberden gives the following account of this complication of small-pox:—“That very formidable symptom, bloody urine, has come on about the fifth day from the first sickness; the eruption in the meantime has hardly risen above the skin, chiefly shewing itself in purple spots and blotches, and resembling varolous pimples only on very few places. The stools are likewise bloody; the very tears have been like lotura carnum; and if a small scratch has anywhere been made in the skin, the blood has for many hours continued to come out, and has hardly been stopped. This hopeless state has been terminated by death in three or four days after the eruption; nor have I known one exception.”—*Comment.* 2d edit. p. 440.

This is not the place for entering at length upon the ancient history of this variety of small-pox; but I may briefly mention, that the green and black varieties of small-pox, characterised by dark-green or purple spots, and bloody urine, are described by Rhases (*Cont.* 420, 2 and 4), and by Avicenna (ii. 1, 3, 6.) These descriptions of this malignant variety of small-pox agree so well with the symptoms of the case which I have related, that it is impossible not to entertain a strong suspicion, at least, considering the circumstances under which it occurred, that the latter must have originated in varolous contagion; and if so, it is a proof (as both the subject of it, and his sister, from whom he must have contracted the disease, had been vaccinated in infancy), that small-pox after vaccination will sometimes assume its most malignant forms. It is deserving of remark, that no more cases of small-pox occurred in the family, or in the neighbourhood. I took care, however, to have every person re-vaccinated who

had come in contact with the patient during his illness, and to have the bedroom and adjoining apartments properly fumigated.

[We have met with, in the instance of scarlatina, the bloody urine alluded to by our correspondent, Mr. Adams, the learned translator of the seven books of Paulus Aegineta.—*ED. GAZ.*]

Banchory, Dec. 30, 1844.

POISONING BY PRUSSIC ACID.

To the Editor of the Medical Gazette.

SIR,

AT this time, when public attention is again drawn to a supposed case of poisoning by prussic acid, or some one of its combinations, it may not be out of place to refer very briefly to some experiments in which I have been engaged, with the view of ascertaining the relative poisonous properties of the cyanides, and of determining whether any antidote to their action should be suggested. The particulars of these inquiries I hope to be permitted to detail in a future communication.

As far as my examinations have hitherto gone, I am led to believe, that when we except prussic acid of a strength of 4 per cent., cyanide of potassium is the most virulent and active of all the compounds into which cyanogen enters; it is, moreover, a salt which is very readily procured, inasmuch as it is kept by almost every druggist for the extemporaneous manufacture of prussic acid.

Five grains of this salt dissolved in two drachms of water, and given to a middle-sized dog, occasioned death in about seven minutes, producing all the symptoms of poisoning by hydrocyanic acid: and when it was given in larger doses its action became the more speedy. For instance, in one experiment I gave half a drachm, in solution, to a spaniel, and before I had time to release the animal its effects had commenced; in 13 seconds the dog fell; and in 32 it lay apparently dead. There were from that time no further convulsions; reflex action had for the most part ceased; the eye could be touched without the lid winking, and the sphincters had relaxed. Yet, notwithstanding this, the heart continued to beat for six minutes, and in many instances I have known it pulsate between 8 and 12 minutes after life had apparently terminated.

The constant effects of these poisons, when given to strong and healthy animals, were,—an apparent giddiness; a staggering walk; an effort to vomit; the animal then generally fell, was convulsed, foamed at the mouth, made great efforts at respiration, shrieked, and died, with a strong convulsive action of all the muscles of the body; the eyes stared; the limbs were extended, and the bladder and rectum emptied. When, however, the animal had been previously exhausted, either by bleeding or want of food, death took place for the most part quietly, without much struggling or cry.

In cases of poisoning by the cyanides, there is always a smell of prussic acid in the stomach, whether the body be opened directly, or some time after death. This, I presume, must be owing to the action of the gastric juice upon the salt, which in this way becomes decomposed, and hydrocyanic acid liberated. The base also with which it was originally combined may be detected.—I have the honour to be, sir,

Your obedient servant,

H. LETHBY, M.B.

Lecturer on Chemistry at the Medical School of the London Hospital.

12, Tredegar Square, Bow Road,
Jan. 9, 1845.

PRACTICAL REMARKS

ON THE VALUE OF THE OPERATION OF PERFORATING THE WALL OF THE CHEST INTO A TUBERCULAR CAVITY,

FOR THE RELIEF OR CURE OF TUBERCULAR
PHTHISIS,

With Comments on the Case of J. G.

By E. O. HOCKEN, M.D.

Physician to the Blenheim Street Infirmary, &c.

[Concluded from p. 485.]

THE importance of placing the disease in a state of rest may be gathered from what we observe in other parts of the body. Affections which are in their nature readily curable, even by the unaided *vis medicatrix nature*, will continue and increase for an indefinite period if they happen to occur in parts exposed to constant disturbance, and will at the same time set up severe constitutional and local distress. I may instance abscesses and fistulae in and around the sphincter ani, which are

kept in a state of disturbance from the actions of the sphincter, and which set up a local and constitutional irritation very similar in kind, though less in degree, to the phthisical vomica and cavern of the lung. The surgeon cures these diseases by freely dividing the muscle by an incision from the fistula into the bowel; and in consequence lays open the surfaces in a state of irritation, and sets them at rest by paralyzing the muscle for the time.

The practical inference I have drawn from these opinions is, that it is of little consequence at what part of the cavern the opening be made from without inwards, provided that a free communication be insured; and that therefore it will not always be necessary to select the most depending situation, but that spot where the disease reaches nearest to the surface, and is otherwise most favourably situate for the operation. If the opening has been made in the most depending position there is a danger of the upper part of the cavity being cut off from the lower (with which only a communication exists) by a process of collapse and healing, such as is evidently going on in the case of J. G.; especially if the cavity be a multilocular one: if, however, the tube be introduced sufficiently high, through the chest, to keep up a communication with the upper part of the cavity, there will be no such danger, but it will insure an obliteration in the first instance of its lower part, extending from below upwards; and thus keep up the communication as long as it is either necessary or desirable.

Dr. Hastings, in his report of the case of J. G., states, "that for a considerable period I had come to the conclusion that the great difficulty of curing phthisis in the latter stage, arises not so much from any obstacle that the nature of the disease offers to the healing process, as to the distension and contraction which the sides of the cavity continually undergo from respiration." * * "The primary object Dr. Barry had in view was the discharge of the fluid within the cavity; the removal of the cause of the secretion was my aim." * * "The persistence and augmentation" [of cavities] "result, I believe, as before stated, from the distending and irritating effects of the air within the cavity."*

Although these views differ from

what I have already propounded, inasmuch as I do not attribute the slightest share of any irritating action to the air itself entering or leaving the cavity, and have already shewn that free exposure to the air is the best plan for curing other diseases similarly circumstanced, still I believe, that, acting on them, he would necessarily arrive at the same practical conclusions. The operation of perforating the cavity, also, would by no means alter the relation of its surfaces to the mere atmospheric air.

To what class of phthisical patients is the operation applicable? My experiments with naphtha have convinced me that the remedy, as a general rule (with the exception of small cavities in that form of phthisis where limited crops of tubercles form, become softened, and are expelled before a fresh crop are again deposited) is incapable of producing a cure; and hence we must look to some other plan of treatment in caverns to assist its beneficial action, and place the parts in a condition admitting of cicatrization. But although the majority of phthisical cavities are incurable by any medical treatment, it will be found that only a certain number of cases are adapted for the performance of the operation under consideration; and these only under certain conditions. In extending the benefits of the operation to others it will be as well to consider in order the cases which are, and which are not, likely to be benefitted by its performance.

In the first instance, we must exclude all the forms of acute phthisis—either where the symptoms are from the first rapid or severe, or where a large deposition of tubercle in the lungs becomes suddenly and completely softened and expelled—the lung in either instance becoming quickly riddled with cavities, and the vital powers giving way from the intensity of the constitutional irritation.

In the more chronic varieties the operation is but little adapted to small or moderate-sized caverns, unless they are seated very superficially, are adherent to the thoracic wall, and are increasing in size in defiance of the most careful and continued medical treatment, especially if they do not give rise to much constitutional disturbance. It is chiefly in large cities, where their progress has been slow, where there can be no doubt of firm

pleural adhesions, and where their walls have become identified with the walls of the chest—being situate very superficially—that the operation will be performed with the best chance of success, and under the most favourable circumstances.

It is necessary also to consider whether the operation will be applicable to cases where more than one cavern exists, or where they exist in both lungs. Provided it were satisfactorily made out that only two caverns (favourable in their nature, as I have already explained) existed in one lung, or one in each, or even one in one lung and two in the other, it would not deprive the patient of all chance, provided he possessed sufficient constitutional power to bear the shock of the operations and the subsequent effects. In such cases it would probably be advisable to perform them at the same time, to give the best chance of combating the immediate effects by removing the phthisical symptoms which had previously oppressed him.

But although the presence of more than one cavity would not deprive a sufficiently vigorous patient of all chance of ultimate recovery, yet it would doubtless greatly lessen this chance; and it would require a very mature deliberation, and a consideration of all the circumstances of the case, before the medical man would be justified even in consenting to the wishes of the patient, much less of proposing or urging operative measures. We must remember that there is no choice of remedies; and that the patient, if not relieved by some means (and the operation, in our present state of knowledge, holds out the only possible chance), will most inevitably die. We give patients a chance of life in an otherwise incurable stage of a most fatal disease; and that by means which, at all events, is little likely to hasten death, if it does not prolong it or produce a cure, and which is far from being a very painful or serious matter, even if two or three openings have to be made.

If possible, a favourable period of the year should be selected for operating, yet in many cases it will be found impossible to wait; for either the patient would sink previously, or be in too reduced a state of health to encounter the shock of the operation. I

am convinced that much depends on the state of health in which the patient is at the time of the opening being made. The most favourable time for operating will be when it is clear that no medical treatment can benefit—the disease advancing so as to threaten death at no distant period—and where sufficient vigour is retained to bear, and triumphantly overcome, its shock, and depressing influence.

The practised auscultator will find little difficulty in determining whether the case be one fitted for operation; and first, whether there be more than one cavity in the lung, its size and relations, the stage it has reached, the contents, the conditions of its walls, as well as the probable connexion which exists with the bronchi—as far, at least, as it is possible to determine these particulars during life. If there be two caverns in one lung, the signs of each do not strictly correspond. I examined a patient recently in order to ascertain how far the case was adapted for the operation, who had come to town expressly for the purpose, and who was most urgently desirous that, at all hazards, it should be performed at once. Beneath the acromial half of the right clavicle there was abundant gurgling, separated by a distinct boundary from a cavity beneath the sternal half of the bone, where there existed very powerful superficial cavernous respiration, and complete pectoriloquy, without any moist sounds. A very large empty cavern existed in the opposite lung. My friends, Dr. Hastings (whose case it was) and Mr. Storks, agreed with me that it would be injudicious to perform the operation in this instance till its value had been more fully proved in less unfavourable cases. The size is easily determined by carefully ascertaining the exact limits over which the signs of cavern can be heard. The relation to the wall of the chest (which is a matter of great importance) can be ascertained by the characters of the signs. If in immediate connexion, the sounds are loud, very superficial, and seem to pass directly into the ear of the auscultator through the stethoscope. If lung tissue intervene, the sounds are distant, much less powerful, and more or less obscured. The next point to be ascertained is

The state of other organs.—As pul-

monary phthisis is often to be regarded but as a part of "a great constitutional disease," it is essential to be well informed as to the structural integrity of other important organs. Colliquative diarrhoea is generally to be regarded as an indication of tubercular disease of the intestinal mucous membrane; but I have found medicinal naphtha mostly capable of restraining it, and hence should not regard the operation as absolutely contraindicating the operation. I should, however, endeavour to cure the affection previously, and failing, should regard it as very unfavourable*. Tubercular laryngeal disease would, at all events, require a separate operation for its cure, and hence would, in most cases, detract greatly from the probability of ultimate success. Severe headache, and other head symptoms, should lead us to regard with suspicion the condition of the brain, and we must carefully determine previously the condition of the heart. Should the state of the lung be very favourable for operation, and the evidences of tubercular and other disease exist in important organs, it will be necessary to calculate carefully the probability of such disease itself occasioning death, and the time the patient might gain even if it ultimately proved fatal, and, having stated our candid opinion to the patient, be guided in some measure by the value he sets on the prolongation of life.

It is essential that firm adhesions should exist between the pleura pulmonalis and costalis, and from all I have observed, as well as from the unanimous assertions of the most competent authorities†, I should never be afraid to recommend the operation when undoubted evidence existed of the cavity being of comparatively large

size, and very superficially placed. Mr. Storks suggests that expansion and depression of the intercostal spaces over a cavity, during respiration, cannot take place without adhesion of the pleural surfaces. The spot for making the aperture should therefore be determined by the physical signs, and by the views I have already mentioned.

The opening, I feel convinced, should be made of a sufficient size to introduce at the time of the operation an elastic-gum tube of about half an inch in diameter, with sufficiently large apertures in its sides, slightly curved at its extremity, and about two inches and a half in length. A drawing of such a tube I submitted to the approbation of Mr. Storks in the case of J. G. As tubes of this kind require to be made some time before they will retain their shape, the surgeon should keep a supply by him, and soften that which he intends to use completely, before its introduction, by retaining it about 24 hours in water kept at about 100° F.

INFLUENCE OF THE NERVES ON SECRETION.

To the Editor of the Medical Gazette.

SIR,

THE other half of the functions of the nervous system, which has hitherto been entirely left out of the calculations of physiologists, consists of the supply of a fluid by the brain to all parts of the body by means of the nerves; in other words, the circulation of the nervous system—a circulation as perfect and complete in every respect as that of the blood through its vessels. There is no novelty in imagining the existence of a fluid supplied by the brain to the nerves, since many of our most esteemed writers have found themselves unable to account for many practical facts, except upon such a supposition, and have consequently argued upon it as confidently as upon any other fully proved premise. Many endeavours have indeed been made to establish the identity of the nervous influence with electricity, and some striking facts have been recorded; it is a point, however, which may safely be left open to future inquiry, because the knowledge of the precise nature of the nervous fluid is of no more importance, as far as the ascer-

* The state of bowels from which J. G. suffered on the 8th of December, is very dissimilar to that produced by tubercular disease of the mucous membrane. My notes state that the patient complained of pain and uneasiness in the hypochondriac and epigastric regions, followed by flatulent disturbance and griping of the bowels. This state was, to a certain extent, relieved by his voiding two stools of a morbidly light colour, but did not entirely disappear till he took the Hyd. c. Cretâ and Dover's powder, which I prescribed for him in the afternoon. The published account of this attack is a condensed and imperfect copy of notes furnished by me to Dr. Hastings. This is a fair specimen of the dyspeptic attacks to which the patient is liable.

† "Louis says, 'If there were no adhesions, neither were there large or medium sized excavations; generally speaking, indeed, there were none of any kind.'"—Trans. p. 36.

taining the various directions in which it flows, than the knowledge of the exact composition of the blood is to the examination of the course which it takes through the arteries and veins. Neither is it of any consequence to determine whether nerves, so fine and delicate, that it is computed that 32,000 are bound up in one cord no larger than a coarse thread, be tubular or filiform, since, if the nervous fluid be *at all analogous* to electricity (which it certainly is), there can be no doubt of its capability of flowing along an appropriate conductor, be it solid or hollow. It is sufficient for my present purpose of describing the course of the circulation of the nervous system, to point out, by referring to the well-known properties of the different kinds of nerves, in what direction they are qualified to conduct any fluid that may be supplied to them by the brain; precisely as it was for that of the famous Harvey, just 200 years ago, to show, by referring to the well-known operation of valves and their position in the heart and veins, that the course of the circulation of the blood was such as, and none other than, that indicated by him.

The first clearly established point to be noted respecting the nerves is, that however intimately bound up together, and apparently mixed, each filament is *single, separate, and independent* in its office: the second is, that no nerve is capable of taking upon itself the function of another; that is to say, *no nerve of volition can become a nerve of sensation, nor the contrary*: the third point is, that as no nerve can assume the function of another, and as volition implies an action from within outwards, and sensation from without inwards, *nothing can take place in either kind of nerve, except according to its proper office*; therefore there can be no reflex action, properly so called, in any nerve. It may to some perhaps appear trivial to insist on such a point as this, but when we find so celebrated an anatomist and physiologist as the late Sir Charles Bell speaking of sensation as being *supplied* to parts by the brain through posterior nerves, which is an impossibility, it must be acknowledged to be one of great importance. The more our knowledge advances, the more precise and significant should our language be: for a grave error may be easily concealed under a loose expression. The fourth

and last point to be noted is, that all nerves except those of the spinal senses *terminate in loops*. Now what are these loops, and how are they formed, becomes an exceedingly interesting question. It is not easy to imagine they can be formed by the ultimate filaments being bent back upon themselves, because if they were so reflected and prolonged even as far as the spinal marrow, the reflected portions, for reasons already mentioned, could not answer any useful purpose, and in the case of nerves of special sensation it is quite certain that the termination in loops is not necessary to the most exquisite perfection of their function, since we cannot conceive any thing more delicate than their sensibility, and yet their extremities are not so disposed. It is fair also to presume that loops cannot be more essential to the anterior nerves in the performance of their office, than they are to the posterior nerves; it is safe, therefore, to conclude that the loop, like the arrangement of the extreme filaments of the general system of nerves, is in no way connected either with volition or with sensation. Now it appears to me that there is, and can be, but one other explanation of the loops, which is that *they are formed in every instance by the union of an anterior with a posterior nerve*. It will be found that this opinion, which I originally put forth nearly twelve years ago, is now confirmed by the dissections of M. Longet, who has distinctly traced such an union of the seventh with the fifth pair of nerves in the face, and who concludes this part of his subject by saying that his "observation, as far as it has yet gone, would seem to render it probable that the nerves of common sensation unite with those of motion in the same way as arteries do with veins; that is to say, that each ultimate filament of a motor nerve originating from the anterior column of the spinal chord, becomes a nerve of sensation at its looped extremity, and as such returns to become united with the posterior column of the chord." I do not consider it at all surprising that the above-mentioned analogy between the different kinds of nerves and the different kinds of blood-vessels should have struck the mind of M. Longet, because it appears to me very obvious; but I do wonder, the idea having once suggested itself, at his having dropped it

again, without pursuing the subject any farther. In reflecting also upon the relation which a nerve of motion bears to a nerve of sensation, the one being *active* and the other *passive*, or, in other words, *positive and negative*, a remarkably striking analogy is seen between them and the opposite poles of a galvanic battery; for if the extreme points of a positive and negative nerve be united as above stated, it is quite certain that the physical means are provided whereby the nervous fluid (be it electric, magnetic, some compound of these two, or *sui generis*) may pass from the one to the other, and operate upon the blood in its transit through the capillaries precisely after the manner of galvanism, in effecting any ordinary chemical decomposition. This idea has been thrown out as a loose thought by Dr. Young, who says, "we may imagine that, at the subdivision of a minute artery, a nervous filament pierces it on one side, and affords a pole positively electrical, and another opposite filament, a negative pole," but without making any attempt to follow it up. I have put the preceding observations together as briefly as possible for the purpose of showing the kind and degree of injury which is inflicted on a part by the division of its nerves beyond the obvious loss of motion and sensation; for of course this wonderful and elegant arrangement for maintaining the secretory function by means of nervous fluid constantly flowing along the anterior and returning along the posterior nerves, *is rendered useless when the communication with the brain is interrupted*.

This view of the nervous circulation, in all parts deriving their nerves directly from the spinal columns, would have been sufficient to enable me to explain the occurrence of inflammation in all such parts, but as I wish also to point out what seems to me to be the true nature of fever, in which all the viscera are so much implicated, and as these organs have no anterior nerves through which they can receive a direct flow of nervous fluid, it becomes necessary to show in what manner this agent may be supplied to the ganglial nerves. If the due performance of the secretory function in the voluntary muscles and general frame of the body requires the constant supply of a current of nervous fluid passing uninterruptedly from a

positive to a negative nerve, it cannot but be still more essentially necessary that all those organs whose office is almost exclusively secretory should be at least equally well supplied, and yet at first sight it would seem to be impossible, because the par vagum being negative nerves, and as such belonging to the posterior columns of the spinal chord, there can be no direct communication *from the brain through them*; their action being in the *reverse direction*. No difficulty was ever overcome by shirking it, and this, which at first appears so insuperable, vanishes as soon as it is examined, with the assistance of the clue afforded by what has been stated respecting the flux and reflux, or circulation of the nervous fluid in the common spinal nerves. If we look to the anatomical arrangement of the visceral nerves, we find them composed of ganglial nerves in company with the divisions of the eighth pair, *i. e. nerves of motion, or positive nerves, united with posterior or negative nerves*, and in this respect therefore standing precisely in the *same relation to each other* as the nerves belonging to the anterior and posterior columns of the spinal chord. Now if we bear in mind what has been stated respecting the reflex current of the nervous circulation which is constantly returning along the posterior nerves towards the brain, coupling it with the fact that it is with these nerves alone that the ganglia are connected, there can be no difficulty in perceiving that a most beautiful provision is made whereby an interrupted current of nervous fluid may be poured into the ganglia, and from them to the extremities of the filaments of the ganglial nerves, again to operate upon the blood as it passes from them to the extreme points of the eighth pair, and again to return along them to the posterior columns of the chord, in the same manner as it had previously done in the common spinal nerves. There are several other peculiarities connected with the circulation of the nervous system which I shall not stop to notice now, because I have shown enough of it to enable me to throw some new light upon the nature of fever, which was the only reason I had for mentioning it at all. I would guard against a misapprehension that may arise from carrying the analogy between the nervous fluid and the blood too far, by observing

that there is this great distinction between these two fluids—the one is the *agent*, the other is the thing *acted upon*. Now the former may effect a visible alteration in the character of the latter without undergoing any change itself; consequently, although an idea of deterioration is inseparably connected in our minds with the term *venous* blood, rendering its immediate return to the lungs indispensable, no such idea ought to be entertained respecting the returning current of the nervous fluid, which, being unchanged, may operate again and again upon the muscles and the blood, producing the same effects at last, wherever it passes from a positive to a negative nerve, as it did at first in the common spinal nerves; just as one circle of galvanism will cause chemical decompositions to take place simultaneously in a series of glass-vessels.

The compass of a letter like this does not admit of my mentioning or even alluding to the hundreds of practical and experimental phenomena which are rendered at once intelligible by the sketch which has here been given of the circulation of the nervous fluid through the spinal and ganglionic nerves. The only farther observation which seems to me to be necessary, and it is important that it should be borne in mind, is that the action of every muscular fibre which, like the heart, is supplied by the reflux current, must necessarily continue while life endures, because the supply of the nervous fluid is incessant, and it must at the same time be independent of the will, this fluid, *in flowing from the posterior into the ganglionic nerves, being beyond the reach of the influence of volition*, which cannot possibly extend beyond the extremities of the anterior nerves.

It is now nearly twelve years since I published my account of the functions of the nerves*, showing the course of the circulation of the nervous fluid, and how the nerves should be classified according to their natural arrangement. It was new, and therefore of course condemned by the critics of that day. The main object of a reviewer is to keep himself quite up to the literature of the day; and with him whatever on the one hand falls short of, or on the other goes beyond his standard, is alike erroneous. Now such an announce-

ment as the discovery of a circulation in the nerves, which scarcely occurs once in a century, takes a man like this by surprise; he is totally unprepared for it; it cannot be right because he forsooth had never dreamed of the existence of any such thing:—his article must be forthcoming by a certain day, so that he has no time to examine it; but as it is not in any of his books it must be wrong; if his wit cannot find him an argument, the last resource, ridicule, is always at his command, and he deals out his condemnation accordingly. The surprising virtues of brandy and salt may receive their share of notice; the absurd doctrine of Hahnemann may be gravely discussed; the pages of the periodicals may help to speed the flight of the lying wonders of mesmerism through the land; but a discovery, the result of years of attentive study, involving a patient inquiry into the whole range of physiological experiment; written so as to be unintelligible except to the purely professional reader, and therefore free from all suspicion of being put forth “ad captandum,” and which, moreover, if true, must inevitably effect a great revolution in the whole science as well as in the practice of medicine, is condemned as unworthy even of examination. Thus it happens that reviewers who profess to have nothing so much at heart as the advancement of science are the very men to deal it the heaviest blows and the greatest discouragement.

I am, sir,

Your obedient servant,

J. W. EARLE.

SOME OBSERVATIONS
ON THE
MEDICAL TOPOGRAPHY, CLIMATE,
AND DISEASES, OF THE BIGHTS
OF BENIN AND BIAFRA,
WEST COAST OF AFRICA.

By W. F. DANIELL,

Member of the Royal College of Surgeons of
England, &c.

[Continued from p. 437.]

NOTWITHSTANDING the vannted assertion, that man, especially the inhabitants of the northern and temperate zones, possesses in a greater degree than any other race a power of adapting his constitution to the most various climatorial influences, the unprecedented sa-

* A New Exposition of the Functions of the Nerves. Longman and Co.: 1833.

crifice of European life in several of our African colonies would lead us to suspect that this statement has been made on very fallacious grounds. If we contemplate the present condition of these settlements, we shall discover how slightly the lapse of time and labour have diminished the number of victims; how little has been done to abate the causes which create these deplorable results: the ominous title of the "white man's grave" has been but too correctly applied to the countries situated within the tropics in Africa. This apparent inability to resist the peculiarities of the African climate can only be attributed to the operation of certain influences belonging to it, and from the agency of which originate the inordinate derangements of the system that are so familiarly witnessed there. Peculiarity of organization alone does not prevent the prejudicial action of these influences; that there are other and equally efficient, but inexplicable states of the constitution that assist to establish this process, there can be little doubt, since if such had not been the case, the dark races would in general enjoy that immunity from febrile diseases which it is so desirable an object to attain. The natives of the East, and the negroes of the West Indies, with those of the northern and southern States of America, are all subject to the same causes which affect the white individual; nay, even the native African, provided he has resided for any length of time beyond their influence, is not exempt upon his return from their morbid effects. What the nature of the causes or elements are which produce the various abnormal states in the human frame, which we designate under particular names, and what peculiarity of constitution or temperament best fits a man to withstand disease-exciting influences, are comparatively unknown to us.

That portion of the west coast of Africa in which the British settlements are situated, forms but a very insignificant district in the vast unknown regions of a continent which possessed, from the earliest records of antiquity, empires whose fame and magnificence historical tradition has transmitted to us through an uninterrupted succession of ages. These colonial establishments are of modern date, all being founded subsequently to the 15th century, in those

divisions of tropical climate comprehended under the appellations of the Windward and Gold Coasts. The main feature in the selection of the sites has been in all probability their prospective commercial advantages; their salubrity being estimated as of only secondary importance. If such has been the case, and circumstances appear to support it, their rise, progress, and history, will furnish us with the most instructive example as to the fallacy of all mercenary speculations, whose groundwork has been an apathetic indifference to the waste of human life. From the commencement these possessions have proved pestilentially destructive to their white populations, and what from periodical epidemics, and other local affections severely afflicting them, heightened from the influence of fear, with exaggerated embellishments, they have acquired a gloomy character, by no means commensurate to the real state of affairs. By degrees an erroneous supposition has led many into the absurd belief that a residence in these countries is almost equivalent to a premature death, and has readily induced the more timid to suspect that they were merely the representations of so many charnel-houses on a larger scale for all who might have the temerity to reside in them. However merited the application of such titles may be, I question whether there are not other localities equally resorted to by European traders, but not included among our colonial settlements, to which this notoriety may be more reasonably ascribed: I allude to the embouchures of the rivers in the Bights of Benin and Biafra.

It would not come within the scope of the present papers to enter into any details of a subject so comprehensive as the description of the Windward and Gold Coasts: if such had been necessary it would have been merely to exhibit a faint outline of their characteristic features in order to point out those geological formations so widely at variance with that tract of coast which will shortly claim our notice. It must be evident to those who are in any degree conversant with the nature, endemic influences, and other local peculiarities, of the British colonies in tropical Africa, that they enjoy many advantages which render them far more salubrious than the marshy mangrove forests of the

Delta. Land more or less elevated above the level of the ocean, of a silicious gravelly soil, calculated for the percolation of moisture, and partially divested of its luxuriant vegetation, will be manifestly more congenial to unacclimatized constitutions, than the alluvial swamps of the bights which are continually inundated by the influx of the tides. From these extensive surfaces of mud and stagnant water, exposed to the action of a torrid sun, are generated those miasmatic exhalations which militate so much against the preservation of health.

Such are the comparative topographical differences in the colonial and other regions of Western Africa, and from a knowledge of which medical authorities have decided that the Windward and Gold Coasts rank as the most healthy; the Gambia and Sierra Leone settlements* next; and lastly those mercantile stations in the bights of Benin and Biafra.

From a careful investigation into the value of this artificial arrangement, I am inclined to imagine its construction has been based on the two first divisions, deriving their insalubrity more from epidemic visitations, and not so much from other sources as has been too commonly reported. This will partly account for the fearful mortality which has at some seasons nearly

* According to the statement of Mr. Ferguson, the present Staff-surgeon at Sierra Leone, the proportion of deaths to the cases of bilious remittent fever among the troops quartered in the northern African colonies, in the year 1825, were, in the

Gambia . . .	as 1 to 157
Sierra Leone . . .	273
Isles de Los . . .	700

The Statistical Report also of Major Tulloch, in reference to the mortality of 1825-6, perhaps more perspicuously indicates the relative loss of life in each of these colonial governments, and their subordinate dependencies. Of the force employed in them, the deaths per thousand amounted in the

Isles de Los	500
Sierra Leone	650
Gambia	1500

Moreover, in the same publication it is stated, that out of 1658 white troops sent out to these possessions (including that of Cape Coast) from 1822 to 1830, 1298 perished from climatic causes, while the remainder, 387, were invalided, and otherwise accounted for. Now, out of these 387 men, 17 died on their passage home, 157 were described as incapable of further service, and 180 as qualified for garrison duty; thus leaving 33 men only who were reported as fit for further service. There are, however, sufficient grounds for belief, that the civilians suffered less from epidemics than the military garrisons, owing to the adoption of customs more in unison with the nature of the climate, or from other means fully as efficacious.

depopulated these places of their white inhabitants, whilst at others they have been remarkably healthy. The greatest sacrifice of life which has hitherto prevailed in the Gambia and Sierra Leone has unquestionably emanated less from endemic causes than any other. This may be easily proved, from the mortality being notably trifling during the intervals of these periodical epidemics, and by the predominant affections not being accompanied by that adynamic type, as was the case when the bilious and yellow remittent fevers occurred in the years 1823, 1829, and 1837.

Could those causes of disease which have been hitherto ascribed to climatorial alternations be more thoroughly investigated, I apprehend we should discover that no small number were founded on very inconclusive data. It is a well-known fact that the notorious insalubrity of Africa has frequently served as the scape-goat on which the blame of those evil consequences, (resulting from the reprehensive indulgence of dissipated courses) might be unreservedly thrown, without the risk of their being disputed or even questioned. When we seriously reflect on the impaired constitutions of two kinds of the human beings who frequent these wastes recklessly, indifferent as to the price of life, we require no further argument for the rational explanation of those abnormal states of the system that so largely swell the amount of victims in these occasional and almost inexplicable pestilences. As this, however, is a topic of great importance, it will be necessary to revert to it more at length in a future portion of these communications.

I shall now commence the description of those regions situated within that division of Western Africa comprehended under the title of the Bight of Benin; regions by far the most deleterious to the unseasoned European throughout the African continent.

[To be continued.]

CASE OF ABSCESS IN THE ABDOMINAL MUSCLES, AND DISEASED PUBIC BONES.

To the Editor of the Medical Gazette.

SIR,

I enclose the inclosed account of abscess in the abdominal muscles, and dis-

ceased pubic bones, should possess any interest, I should feel obliged by your inserting it in your valuable journal.

I am, sir,

Your obedient servant,

WILLIAM SMITH,

7, Upper Berkeley Place, Clifton, Surgeon.
Bristol, Jan. 7, 1845.

P.S.—Mr. Arnott's cases of abscess, which appeared in your last number, suggested to me the publication of this case, which I have long had in my note-book.

July 1842.—Mary G., æt. 14 years, admitted into the Bristol General Hospital about a week since, apparently suffering from some disorder of the digestive organs. Some time since she received a blow in the pubes, and afterwards she continued for some time unsteady in her manner of walking. After having remained in the hospital for about nine days, an abscess formed under the muscles of the abdomen. Its contents were evacuated by a longitudinal incision in the lower portion of the abdomen.

July 12th, two days after the evacuation of the abscess, she was attacked with all the symptoms of acute peritonitis. In spite of appropriate treatment, consisting in the free use of leeches, mercurials, and opium, she became rapidly worse, and died on the night of July 13th.

On reflecting the skin, the muscles of the abdominal parietes were found to be of a dark greenish colour, and much saturated with pus, which was also infiltrated between them and the fascia transversalis. The bones of the pubis were much diseased. There was very extensive peritonitis, the intestines being glued together by the inflammatory action. The bladder presented on its mucous coat a thick layer of fibrine.

It may be remarked, that this case bears a striking resemblance to some cases of diseased spine, producing psoas or lumbar abscess. Here, however, the proximity of the peritoneum afforded a means of death, which saved the patient the slow exhaustion attendant on spinal disease.

THE ALLEGED MURDER AT SALTHILL.

(For the London Medical Gazette.)

Post-mortem Examination of SARAH HART, by order of JOHN CHARSELEY, Esq. Coroner for Bucks. Jan. 2, 1845, 18 hours after death.

THE deceased was 41 years of age, of small stature, rather spare habit, fair complexion, light hair inclining to grey, pale face naturally.

The body was lying on the floor of the room, as she died; the head on a pillow, jaw tied up. The left stocking was half down the leg, there were no shoes on the feet, and the head was without a cap. The shoes (slippers) and a cap were on the opposite side of the room when the body was found by a neighbour.

The surface of the body was pale, the extremities were rigid, a little animal heat still existed in the fleshy parts of the thighs, the countenance had a calm expression, the pupils were half-fully dilated, there was no odour about the body but the usual cadaverous smell.

The body was next stripped. There were no marks of violence any where discoverable; the under garment was extensively stained with blood. It is stated that deceased never used the usual protection during the menstrual period, and that function was going on at the time of her death.

The thorax and abdomen were laid open. There were rather extensive adhesions of the pleural surfaces on both sides of the thorax, and a white patch, the size of a shilling, on the heart. These morbid appearances were of long standing; the adhesions were very firm, some close, others of considerable length.

The heart was flaccid, but full of blood on the right side; there was no fluid of any description, exceeding the usual serosity, in the pericardial or pleural sacs.

The larynx, pharynx, and trachea, were free from obstruction or disease. The lungs were healthy; no tubercle, induration, abscess, or other disease. The cavities and valves of the heart were perfectly healthy.

There was no odour differing from that of an ordinary dead body in the thorax or abdomen. The closest possible

attention was paid to this point, by the two other medical men who were present, and we were all agreed on this point.

Some adhesions of the convex surface of the liver to the diaphragm existed: they were of much the same appearance as those in the thorax, and probably of consentaneous origin. There was no recent disease. The abdomen was loaded, but not burdened, with fat; its venous system was filled with black fluid blood. The stomach was about half full; the gall-bladder contained but a small quantity of bile; the substance of the liver quite healthy.

The veins of the pelvic cavity were very full of blood, especially those of the ovaria, fallopian tubes, and uterus. This viscus was somewhat increased in volume, and felt rather spongy between the fingers. The bladder was empty, but *flaccid*. The external genital organs were of a bluish cast of colour; they were free from injury; there were no appearances as of connexion having recently taken place. The fore-finger passed up the vagina was withdrawn smeared with sanguineous secretion. The os and cervix uteri healthy. A section of the uterus shewed its structure of a pink hue; the parietes a little increased in volume, and its interior containing sanguineous secretion and mucus: it was *unimpregnated*. The ovaria were healthy. The kidneys were quite healthy; the cortical and tubular portions distinct, and of the usual contrasting appearances.

The œsophagus, stomach, and duodenum, were now removed, and the stomach laid open. It contained rather more than half a pint of pulpy contents; consisting of chyme, with a few shreds of coarse beef (apparently salt boiled), and some portions of apple.

The whole contents had an intensely sour smell, exactly resembling that of food rejected an hour or two after the commencement of digestion from a disordered stomach; but there was no odour that could possibly be considered in any respect like prussic acid. The contents were hermetically sealed for analysis.

Some tenacious mucus smeared the interior of the stomach; there was no unusual vascularity.

The head was next opened. The venous system was filled (not gorged, hardly distended) with black and fluid

blood; there was no extravasation of blood or effusion of serum in the arachnoid sac. The brain was removed: its vascular system was in a state of integrity, the circle of Willis naturally formed. Careful sections of every part of the cerebrum and cerebellum were made: there was no effusion of blood, abscess, or tumor of any part.

The vertebrae were all sound.

The sudden manner of death in this case, and absence of the characteristic smell of prussic acid, naturally led to the inference that if any poison had been taken, it would prove oxalic acid: the usual tests were therefore tried for this poison, but with negative results; and the same may be said of all the ordinary mineral and acid poisons. But prussic acid was unequivocally proved, by chemical analysis, to be present, and in considerable quantity. The processes followed in this investigation will be given at the proper time.

E. W. NORDELADE, Surgeon.

Slough, Jan. 11, 1845.

INCORPORATION OF GENERAL PRACTITIONERS.

To the Editor of the Medical Gazette.

SIR,

THE project for the incorporation of general practitioners in a new College appears to have been welcomed with the highest satisfaction by a great proportion of that numerous body for whose benefit it is designed. They seem to hail it as the means of securing advantages which are not offered them by Sir James Graham's Bill; such as corporate rights, the power of regulating the education of their own class, and the privilege of indirect representation in the Council of Health, in common with the Colleges of Physicians and Surgeons.

All these rights and privileges are regarded by many as very desirable. The proposition is a specious one, and a great struggle will doubtless be made to obtain a charter of incorporation. But, let me ask, have the general practitioners calculated on the probable results of their scheme? Have they counted the cost? Have they estimated its ultimate effect on their position?

They will surely admit that no measure of reform can substantially benefit them, which does not hold out oppor-

tunities to *all*, for attaining promotion and distinction in the ranks of the profession.

Now, under the present system, and more freely by the new Bill, facilities of this kind are offered to every general practitioner.

There is not a village doctor throughout the kingdom, who, if he possess the requisite amount of personal and professional qualification, may not rise to the most distinguished station which the practice of our art can confer. He may become a Royal Accoucheur, or a Sergeant-Surgeon; and the old Colleges of the land open their portals (though somewhat stiffly, it must be confessed) to aid him in his ascent, and to confirm him in his fairly earned dignities.

On the other hand, what will be his position and prospects when he has joined his new College? What assistance will this afford him in his career? To what will the highest offices and honours of such institution lead? What professional status, what public reputation, will they confer?

Whatever else they may do for him, they will certainly *fit* him. To ascend *then* will be next to impossible. He will find himself in a corporate cul-de-sac: a way into it, truly, but no way out.

“Facilis descensus Averni;
Sed revocare gradum, superasque evadere auras
Hoc opus, hic labor est.”

Surely those who are now so eager to enter this embryo College cannot have reflected on their probable condition, either as individuals or as a body, when they are shut into it. “Contentment is a virtue,” which they might indeed endeavour to exercise; but their present restlessness and dissatisfaction rather lead one to expect that in a few years many would see their blunder, and uncivilly turn their backs on their adopted mother, as they now do upon their venerable nurse of Blackfriars.

Let, then, this delusive project be well sifted, before it be pushed too far to permit an honourable retreat to its abettors.

The mass of the profession seem to think that the State is bound to grant them the privileges of incorporation somewhere or other. But the State is under no obligation of the sort. It is, indeed, the duty of a paternal Government both to require that those to

whom it grants a license to practise medicine shall satisfactorily prove their competency, and also to afford all reasonable protection to the practitioners whom it has thus licensed.

If any of these licentiates are ambitious of Collegiate honours and corporate privileges, let them devote themselves to a longer and more extended course of study and preparation; or else let them shew their fitness for the distinctions to which they aspire, by the extent of public confidence which they enjoy.

The modification of the Government Bill proposed in a recent leading article of the *MEDICAL GAZETTE*, and especially the suggestion for the establishment of a *ROYAL COLLEGE OF OBSTETRICIANS*, afford the real solution of the difficulty in which medical reformers, great and small, find themselves involved.

The latter idea is, however, not a new one. In the second volume of the *Provincial Medical Journal* is a letter (dated 15th June, 1841), addressed to the Secretary of the Exeter Hall Conference of Medical Delegates, in which the following passage occurs:—

“The creation of a fourth body in the profession, a College of Midwifery, is a point worthy the deliberate consideration of the Conference. Neither of the other corporate bodies are suited to examine in that branch of medical practice, which is surely of sufficient importance, both with reference to the profession and to the community, to be regulated by its own board. All the Fellows of such a College might be empowered to elect a Council, provided they did not retain the right of voting in either of the other corporations; and the Council might be composed of physician- and surgeon-accoucheurs in equal numbers.”

A golden opportunity now offers for instituting a Midwifery College. For from whom would a charter come so gracefully as from a Royal Wife and Mother? Or who would be a fitter President than the distinguished accoucheur on whose skill and discretion our gracious Sovereign and her attached subjects rely with so much confidence during those oft-recurring seasons of trial, on the issue of which the destinies of this nation may be said to depend?

Establish, then, the College of Obstetricians, and the College of Pharmacists, and we have at once all the elements of a GENERAL LICENSING BOARD; one of simple yet comprehensive construction, the members of which should be appointed by the Council of Health, and its certificate required of all who enter the profession.

Each College would feel the strongest inducement to maintain the respectability and interests of its Fellows, and to promote the advancement of the particular department of medical science over which it would preside; while a race of practitioners, well informed in all the branches of the profession, would be provided for the community.

Consider, also, the calming effect of such a measure on the strife and disaffection which now prevail in the College of Surgeons. There are many members of this College, men of high respectability and extensive reputation, especially in the practice of midwifery, who have been passed over (whether rightly or wrongly is not the question) in the late selection of Fellows, and who have no idea of submitting to an examination in advanced life for the sake of obtaining what to them might prove a merely nominal distinction. Make the *amende honorable* to 500 of the senior of these gentlemen, by nominating them the first Fellows of the College of Obstetricians, and let those who might afterwards seek admission into that College (at the age of 24 or 25) produce evidence of a higher scientific and practical qualification in this department, than would be required of the general licentiates.

I am, sir,
Your obedient servant,
CHIRURGUS.

Jan. 4, 1845.

MEDICAL GAZETTE.

Friday, January 17, 1845.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medice tueri; potestas modo veniendi in
publicum sit, dicendi periculum non recuso."

CICERO.

INCORPORATION OF GENERAL PRACTITIONERS.

ALTHOUGH it is universally admitted that medicine, as an art, is one and

indivisible, yet in these islands there are no fewer than nineteen different sources of medical honour and privileges, nineteen different modes of education for attaining them, and fourteen varieties of professional rights and immunities attached thereto. In spite of this anomalous condition of things, the general practitioners of England are now bestirring themselves with zeal and energy to obtain a charter of incorporation, so as to form a faculty apart, independent of all others at present in existence. The Society of Apothecaries, as if foreseeing an end to their labours, have avowed themselves willing and anxious to afford every assistance to the licentiates in this their struggle for collegiate organization. Having discharged the duty confided to them by the Legislature, having succeeded in materially raising the character and attainments of the class of general practitioners, the Worshipful Society, irrespective of personal or corporate considerations, are now, after thirty years' probation, prepared to surrender their trust into the hands of their constituents. Previously, however, to taking any decided step, they deemed it proper to consult the Home Secretary, who informed them that "he is ready to receive any mature plan for incorporating a new body of general practitioners; but that before he can form an opinion, or even consider such a project, all the details of the scheme must be laid before him; and the names of the leading persons who promote it, and who are parties to the proposed organization, must be declared."

This expression they have hailed with the utmost satisfaction, and have thereupon at once determined to afford their co-operation in maturing such a plan as may commend itself to the judgment of Sir James Graham, and secure his approval. Unanimity, they very wisely observe, should if possible

prevail on this important subject, "because any material disagreement in principle or detail would afford a strong reason for the Secretary of State withholding his consent to the scheme altogether."

Now while we grant that the Society of Apothecaries have acted with great discretion and liberality in this matter, and that no technical objection can be urged against the measure of incorporation in question, we entertain strong doubts as to any ultimate advantages which the general practitioners of England would derive therefrom. We do not believe it would at all better either their present or their future condition. They complain that the College of Physicians bears no sympathy towards them; that they have been spitefully used by the College of Surgeons, that very College of which the great majority of them are enrolled as members; and they now say, we shall not rest satisfied until we are established as a distinct *third estate*, with rights and privileges of our own. In their present position the general practitioners naturally address themselves to the Society of Apothecaries, who say, mature a plan which may meet the approbation of the Home Secretary; and the Home Secretary, employing the *argumentum ad hominem*, replies in a manner which might be interpreted thus: show me your men; prove to me that they are distinguished for their learning; that they have advanced the boundaries of medical science; that they, as constituting at least nine-tenths of the medical men of this country, have contributed, in proportion to their number, to render it pre-eminent above other nations by progressive improvement in the healing art, by the discovery of new means of alleviating pain, or of remedying disease. In other words, if Government is to found a new College, let good cause be shown for its foundation.

There are some among themselves who do not hesitate to allege that the parties now so zealously engaged in the movement going on here are actuated in their proceedings by hostility to the Royal College of Surgeons, and who question "whether their purpose be, not so much to humble that institution as to promote the *welfare* of the general practitioners*." If such be their motives, their agitation will prove a dead letter. But would the degradation or annihilation of that institution tend to mend matters? By no means. We are convinced that a considerable amount of the public confidence enjoyed by the general practitioners is due to the circumstance of their possessing the diploma of a college from which a Hunter, a Cline, an Abernethy, and a Cooper, emanated. Hence, secession from that body would be more likely to abate than enhance the general estimation they now so deservedly hold.

We entreat our professional brethren to ponder this in their hearts. We would remind them that there is ample room for reform as regards every department of physic. Let us with one accord demand checks, seek for guards, insist on securities against the unlawful encroachments of unqualified pretenders. Let us entrench ourselves behind strong defences, and fortify ourselves, with all care, against the assaults of the ignorant and illiterate, who are now defrauding us of our just gains. But let not the spirit of faction step in and damage the good cause. Nor let it be insinuated that the aim is not so much to put down as to obtain a monopoly of quackery.

SCHOOLS FOR THE SONS OF MEDICAL MEN.

WE augur favourably of a proposal for the establishment of schools for the

* Letter from Mr. Cole, of Bewdley, in Provincial Medical and Surgical Journal of Jan. 8, 1845.

sons of medical men, on such moderate terms of expense as may be consistent with a course of education of a high character; being convinced that preliminary education throughout the English medical profession at large has been long at a very low ebb. An additional argument in behalf of an establishment of the kind is deducible from the fact, that the profession at the present moment is completely overstocked, and many a practitioner is withheld from affording his sons an education befitting their station in life, simply from want of means. While we strongly advocate the prime importance of elementary instruction, we would at the same time caution parents and guardians against bringing up youth for a calling where the chances of earning an honest livelihood are so precarious*. Government might very well impose a heavy tax upon every individual entering the profession during the next ten years, so as to provide a fund for the support of destitute supernumeraries.

The project originated at the annual meeting of the Provincial Medical and Surgical Association, held at Northampton, in August last, and the following gentlemen were nominated as a committee for carrying it out:—Dr. Forbes, Dr. Kerr, Dr. Heygate, Dr. Edwards, Dr. Hodgkin, Dr. Hardwick, Dr. Budd, Mr. Hodgson, Mr. Nunneley, Mr. Daniell, Mr. Wallace, Mr. Martin.

Schools on a similar plan to that now recommended have been founded by members of other professions, as the clergy, and the officers of the Royal Navy, and have proved most useful seminaries for learning.

It is proposed, in the first instance, to raise, by way of capital, the sum of £2000 at least, as the basis on which all their future proceedings must rest; and it is recommended that there should

be three forms under which the required amount of capital should be raised, namely, shares, donations, and benefactions.

“1. *Shares*.—Proposals to be issued for the disposal of three or five hundred shares of the value of twenty-five pounds each; the sum of ten pounds on each share to be paid in at a banker's, at the time of subscription, subject to further calls, as more money may be required.

Shareholders to be of the medical profession; and no subscriber to hold more than eight shares. The transfer of shares to be to medical men only. For each share the subscriber to have the right of nomination for one boy at a time, provided that the full amount of each share shall have been paid up; but no share shall authorize more than five consecutive nominations; nor be available for more than fifty years, unless the original shareholder shall survive that period. And the holder of any number of shares not to be entitled to more than three nominations at a time.

“2. *Donations*.—They propose that an additional amount of capital shall be raised under the name of donations, to form part of the same stock; and to confer privileges during the life-time of the donor, and no longer: but donors to be at liberty to nominate prospectively. The lowest donation conferring privileges to be twenty pounds, which shall confer the same privileges as shares of twenty-five pounds: these donations shall be paid in full at the time of subscription. Donors of fifty pounds to be entitled for life to the nomination of two pupils always in the school. Donors of one hundred pounds and upwards, to be entitled for life to the nomination of three pupils contemporaneously in the school: and the nominations of donors of the largest sums to be entitled to preference. Persons of other professions to have the right of becoming donors, with equal privileges as to right of nomination, with those of the medical profession: but in this, as in all other cases, as subsequently stated, two out of three nominations must be in favour of the sons, grandsons, nephews, or wards of medical men.

“3. *Benefactions*.—As there will doubtless be many members of the profession, who, without wishing to incur the responsibilities and duties of

* See some remarks by Mr. Alfred Taylor on this point, in a former part of this No.—ED. GAZ.

the shareholders and donors, will be anxious to promote the interests of an institution of such inestimable value to their brethren, it is proposed, in the third place, to adopt an additional form for the increase of the capital, by means of independent contributions under the name of Benefactions.

"As no privilege will attach to these contributions, they will bear no fixed amount, but the smallest as well as the largest sums will be acceptable, and will be applied to the promotion of the general purposes of the institution."

The committee consider it advisable at present to prepare for the establishment of one school only, consisting of not less than two hundred, nor more than three hundred boys. The following are the regulations touching the admission of pupils and government of the school.

"1st. Pupils to be admitted by nomination only.

"2d. The sons, grandsons, nephews, or wards, of members of the medical profession, to be eligible for admission at the charge, for board and education, of thirty guineas per annum, with three guineas as an entrance fee.

"3d. The sons of persons, not being the sons, grandsons, nephews, or wards, of members of the medical profession, to be likewise eligible for admission, but at the annual charge of forty guineas; the entrance fee to be the same in both cases.

"4th. Payments to be made half-yearly, in advance, and to include all expenses, excepting for printed books, which will be a separate charge, at prime cost.

"5th. Shareholders and donors not to be allowed to nominate pupils nor being the sons, grandsons, nephews, or wards, of members of the medical profession, in a larger proportion than one in three.

"6th. Boys not to be received before they are ten years of age, nor after they are fourteen; nor to remain at school longer than until they are eighteen years of age.

"7th. Before pupils are received, they are to be approved by the council of the school.

"8th. The course of education to be of a high character, liberal and comprehensive; calculated to produce well principled, well disciplined, and well

stored minds, elevated by religious instruction according to the doctrines and discipline of the Church of England.

"9th. The officers of the institution to be a president, vice-presidents, trustees, treasurer, auditors, and secretary.

"10th. The government of the Institution to reside in a Council, twenty-four in number, being all members of the medical profession, elected from the shareholders and from the donors, with power to apply the capital to the purchase, renting, furnishing, and fitting up of appropriate premises: they shall have the management of the property, and the entire direction of the affairs of the society. The members to continue in office three years; and to go out in sections of thirds, but to be immediately eligible for re-election. The Council to have power, with consent of the president, to add to their number such contributors to their funds as they may deem qualified to render essential service to the institution, subject to confirmation at the next annual meeting.

"11th. The annual meetings of the shareholders and donors to be held either in London, or at the school; or wherever the Council may consider to be most eligible. At such meetings, or at special meetings to be convened by the Council, there will be power to revoke, or add to, or alter regulations, provided that due notice has been given."

Subjoined is the list of subscribers during the last week of November 1844.

Shareholders.—E. Daniell, Newport Pagnel, 1 share; T. Martin, Reigate, 1 share; E. Wallace, Carshalton, 1 share; T. Nunneley, Leeds, 1 share.

Donors.—A. Robertson, M.D. Northampton, £100; T. Martin, Reigate, £100; J. Hodgson, Birmingham, £100; Sir B. Brodie, Bart. London, £100; J. Forbes, M.D. London, £100; A. Hardwick, M.D. Kensington, £20; Sir J. Clark, Bart. London, £100; P. J. Martin, Pulborough, £25.

Benefactors.—The Misses Wallace, Carshalton, £25; E. Wallace, Carshalton, £20.

WE would invite the attention of our readers to an article, entitled "Society and the Doctors," that has just appeared in the second number of "Young England," and to which we may probably refer hereafter.

MOVEMENT IN THE PROFESSION.

A MEETING of the medical profession at Cambridge took place upon the 3d current, R. M. Fawcett, Esq. in the chair. The necessity of some alteration in the laws relating to the medical profession was admitted, and thanks were tendered to Government for having brought the subject before the notice of Parliament: but an opinion was at the same time expressed that the proposed Bill, though containing some beneficial clauses, requires alteration in several important points. A Central Council was approved, while the constitution of the Council of Health and Medical Education was objected to, because no provision is made for the licentiates in medicine and surgery. The annual publication of a register, under the authority of Government, was deemed highly desirable, but the removal of all restrictions upon unlicensed practitioners was opposed, and the adoption of some summary means of restraint recommended. It was further submitted that the graduates in medicine at the Universities of Oxford and Cambridge should not be subject to the necessity of undergoing an examination at the College of Physicians previously to being registered by the Council of Health.

At a meeting of medical practitioners of Aylesbury and its vicinity, held at the Buckinghamshire Infirmary, on the 8th current, Robert Ceeley, Esq. in the chair, several resolutions were unanimously carried. Great disappointment was expressed as to the inadequacy of the Bill. It was contended that legislative enactment should protect the public against the unqualified, and maintain the rights of the qualified practitioner; that the constitution of the proposed Council of Health is objectionable, and the exclusion therefrom of the general practitioner prejudicial to the public and to the bulk of the profession; and that it is necessary to obtain a charter for the incorporation of the general practitioners. A Provisional Committee was at the same time formed for the organization of the "Bucks Medical Association."

MESMERISM APPLIED TO
SURGICAL OPERATIONS,
OBJECTIONABLE.

To the Editor of the Medical Gazette.

SIR,

IN your No. for the 13th January is inserted a letter from Mr. John Chatto on the above subject, in reply to which I respectfully submit a few remarks, premising "that I am as sceptical as most persons as to the ultra pretensions of the professors of the art"—if by this term be understood the conversion (by Deleuze) of water into alcohol, or (by Miss Martineau) into wine, the reduction in a fortnight of a considerable projection of the lumbar vertebrae (vide *Instruction Pratique*), or the elongation in six weeks of a shortened leg some three inches; not forgetting reading with the oeciput or the big toe, the seeing through (imperforate) stone walls, the ghostly translation to Hull of one bodily at Tynemouth, or the clear notions in pathology and therapeutics of a cook or a lady's maid. As to all such pretensions, it surely is not "a very strange procedure, at the present day, to condemn them by *à priori* reasoning alone," when we keep in view the data on which such reasoning is founded! Although "the test of experiment has not been applied" directly and expressly, let us not lose sight of the indirect experiments that we have made, which of course are available on other occasions although not expressly instituted. Our outward senses, given us by Providence to relate us to material nature, are far from being "infallible"—at least, taken separately; each requires to be checked by others, in even ordinary cases, and at times, were it not for the dictates of reason—to which they are clearly subservient—even more senses than one may be deceived, aye, and more individuals than one*. Let us make a just estimate of reason and of our senses, overrating neither at the expense of the other; agree they must, before our faith or confidence can be commanded; and we cannot receive anything in opposition to either the one or the other. As to the "infallible test of experiment," how is it that past experiments are now to be denounced as fallacious? Is our daily and hourly acquaintance with Nature's phenomena, tending over a lifetime to conclusions unquestioned, tested by thousands of our race under such a variety of circumstances, to be spurned, and give way to the mushroom-like and chameleon-like "experiments" of mesmerists? The vast majority of our profession, and of the intelligent public, too,

* See Miss M'Avoy's case at Liverpool, by Dr. Renwick, some twenty years ago.

will answer in the negative. For even among the humble-minded (or would-be-so) who receive in child-like simplicity the evidence of their senses at all times, hazarding no conjectures or hypotheses,—how is it, sir, that our experience of the properties of the eye and its component parts, of the tissues composing the skull and its coverings, and of the big toe, has up to this time been a blank? If so, how can we talk of the “infallible test of experiment?” In short, whether or not the evidence of our senses be worthy of our confidence, such pretensions are at once proved to be false; if our past experience be worthless, much more so must be the experience of our mesmeric friends, for the testimony of our senses can never again be received. Under the semblance of an openness to conviction through appeals to our senses, let us not detract from the authority of reason, nor offer a disguised insult to our senses themselves. We all feel, and practically allow this, as proved by that very scepticism and apathy which the votaries of such a delusion so generally deplore. It would be well for Mr. Chatto and others to hesitate before they speak of “dogmatical and unphilosophical course,” “yielding scepticism,” “culpable apathy, and a want of due recognition of professional responsibility,” or throw out hints and insinuations about “neglected opportunities of alleviating human suffering;” let the advocates of both sides of this and similar questions reflect lest they be caught doing what they themselves so loudly condemn; lest, while indignantly repelling an “impeachment of veracity,” or “a charge of collusion,” they be found stigmatising all who differ from them as devoid of candour, reason, and humanity. To Mr. Chatto, rejecting, as he seems to do, the “ultra pretensions,” the foregoing remarks may appear irrelevant; but they are made under the decided conviction that mesmerism is one entire whole, of which the “ultra pretensions” are the hitherto invariable conclusions—the Charvdis destined to engulf all who may have got within its outer current—scarcely perceptible, but nevertheless centripetal. Shocking to our reason, and contradictory of our experience, as such monstrous allegations unquestionably are, is it not matter of melancholy experience that we cannot trust any one for not ultimately believing, blindly and implicitly, these “ultra pretensions?” Are we not warranted in this speaking, when we refer to the already avowed votaries of mesmerism, and bear in mind their honest worth in many cases, and, more strange and disheartening still, in some instances their intelligence? Looking to the past, I respectfully offer it as my own opinion, that little if any reliance can be placed even on medical men for not finally admitting even

such “ultra-partisans,” when once they have so far forgotten their “professional responsibility” as to give but the semblance of an adhesion to mesmerism, by gravely setting about its examination, unless as a delusion, illustrative, certainly, of the workings of the mind, and of mental influence over bodily sensation and function—the nature of which is still unknown to us; its extent we may call boundless.* What medical man, with these ultra-pretensions before him, and remembering the “conversion” to mesmerism, in all its rankest folly, of but too many “scientific and unprejudiced men,” would be warranted in entering upon “a patient, deliberate, and candid examination into the whole matter?” Where is the proof, nay the probability, or even chance, that “a repetition of the experiments on an enlarged scale” by any body of men whatsoever, “will prove decisive” of such a question, or satisfactory alike to the “credulous” and “deluded” mesmerists, and to their “unphilosophical” and “bigotted” opponents? Have we ever yet seen experiments, observations, or discussions, settle any question of that class to which mesmerism but too clearly belongs? Such matters involve our feelings more certainly and extensively than they do our careful mental efforts; the wish, with each party, becomes father to the thought; conclusions, more dependent in such cases on our mental constitution and temperament,—having been hastily arrived at,—sophistry is invoked, and *quasi*-facts are impressed, to bolster up opinions already adopted, we may say mentally assimilated, by the respective parties; each, feeling but too soon his identification with certain views, flushed at one moment with appearances of success and a prospect of victory, or anon nettled by impending defeat, becomes only less able to retrace his steps as advance becomes difficult; the one, piquing himself on his philosophical acuteness and rational circumspection, is “sorry to see so much excitement and credulity” in his opponent, who, admiring philosophical candour above all things, deplores “the scepticism and apathy” of especially the medical profession. No good ever yet came of arguments or experiments in such a cause; in all such we see the same sort of men upholding—the same kind of men opposing—the same feelings worked upon—the same style of going to work adopted—the same terms and epithets used—the same unsatisfactory termination in every case. The history of one is that of all of them; and instead of any hospital-surgeon entering on such an inquiry as that proposed by Mr. Chatto, I would rather recommend our psychologists and asylum-physicians to embrace

* See Fox's Book of Martyrs, Hecker's Epilemics, McKay's Popular Delusions; also Dupotet and Deleuze.

the present opportunity, among the many afforded by this and every age, to advance our knowledge of mental operations and their action on the body.—“But to do good!” exclaim mental mesmerists, “to alleviate mental sufferings!” Take it, sir, even on this benevolent ground; and it may be a question whether the act is not one of pseudo-philanthropy, one of disguised and unintentional cruelty, just as, under the semblance of an undisputed homage paid to the evidence of their senses, men may grossly insult the same, and prove, by their very display of subserviency, that their adhesion and good faith are never to be relied on. As medical men, know we not of a thermometer bulb placed beneath the tongue, and of bread-pills, &c., having wrought good cures? Would Mr. Chatto for a moment consider the claims “of *mica panis* or a thermometer bulb?” Would he, now, really vote for “a searching investigation into the whole subject by a body of scientific and unprejudiced men?” Surely not; it is of course to be understood that Mr. Chatto, knowing the properties (or rather the inertness) of such means, and that they are the apparent agents only, in a *boué fide* cure, and with his acquaintance of the human machine, its nervous system, its subjection to the mind and imagination, &c. would, like myself, pass from the outward signs to the circumstances under which they were used—the state of mind of the patient on whom, as Mr. Chatto knows, neither the glass bulb nor the bread pills, nor, allow me slyly to add, “the passes,” would act after once their nature was understood; a remarkable difference between animal magnetism and galvanism, bread pills and ipecacuan; and throwing, in my opinion, some light on the curative action of the once much used *brassica oleracea*, of new or costly, or highly puffed, or gravely prescribed remedies—to wit on curative action being of a twofold character or corporeal, and indirectly on the body through the mind and imagination. In therapeutic investigations the former or direct action is generally but too exclusively attended to—the latter neglected, although known and admitted; yet the distinction is an important one, and would save much needless or misdirected labour to many of our brethren—under the heads of mesmerism, diamond-powder, quack-nostrums, hydro-pathy, homœopathy, and newly introduced drugs. These two modes of action may, and should be, separately studied for scientific purposes; their confusion precludes the possibility of our ascertaining precisely the action of a drug, or even whether it have any action at all. The indirect operation of an agent on the body through the mind, so far as the present state of our knowledge enables us to judge, seems to be such as to render it matter of little or no moment

what agent we employ. Although we possess abundance of materials, yet the subject has never been treated apart, or even had a reasonable amount of attention; in my humble opinion this is the most promising chance we have of clearing away many uncertainties of action and discrepancies of writers. However, such a *modus operandi* there undoubtedly is more or less perhaps in every instance of medical treatment; and the question is, how often and how far are we warranted in availing ourselves of it? Opinion varies on the point of course, and as usual we have a stern and uncompromising man at one extreme, a man of great worth and straightforwardness, and opposed to him an amiable and agreeable man; these parties naturally differ; the former speaks of “imposition,” and disdains “such quackery,” while the latter “would never hesitate,” nay “be only too anxious to relieve a patient by any means whatever.” A third, and intermediate section, would discard every approach to deception in the case of the intelligent, but would, to avoid useless argument, or an appeal to harsh means, in the case of an unruly child or an obstinate dotard, have recourse at once to some degree or modification of deception; but of all things, Mr. Editor, whichever course we may pursue, let us never deceive ourselves. To my amiable friends, then, who would say

“And therefore as a stranger give it welcome,
There are more things in heaven and earth,
Horatio,

Than are dreamt of in your philosophy:”

I would respectfully suggest that strangers’ claims be not allowed to shut out those of old and well tried friends—strangers so received and made way for will but feel themselves “tenants at will,” under a capricious landlord.

In conclusion, sir, allow me to insist on the expediency of—First, distinguishing (among “things not dreamt of in our philosophy”) between such alleged facts as are at variance with truths ascertained, as far as facts can be, by reason and our senses, from those which, how novel soever they may be, are consistent with, or at least not contradictory of, our past experience of natural laws and phenomena; secondly, distinguishing such agencies as operate, at all events, directly on the body, as galvanism and ipecacuan, from those that only act indirectly on the body through the mind or imagination, as bread pills, mesmeric ceremonies, and the like; and lastly, of not wincing under harsh epithets applied to us by our over zealous, but doubtless, well-meaning opponents, nor of returning them a Roland for an Oliver.

Apologising for the unusual length of my epistle,

Believe me, sir, respectfully yours,

MEDICUS.

Jan. 1845.

ST. MARYLEBONE INFIRMARY.

To the Editor of the Medical Gazette.

SIR,

I HEARTILY agree with the remarks of your correspondent in the current number of the MEDICAL GAZETTE, on the very considerate and just conduct of the guardians of the poor of St. Marylebone, in having shown a determination to discontinue gratuitous medical services.

But while this independent and enlightened Board has adopted this principle from the fact that paid officers can best be made responsible for the due performance of their duties, I must beg of you to allow me to ask two or three questions as to the conduct of the members of our profession in these affairs.

When the parish guardians want the services of the Law or of the Clergy, do the members of those professions insist on obtruding the offer of their gratuitous services? No. It is unnecessary to multiply the numberless parallel instances.

Then why do the members of our despised and oppressed profession so obstinately persist on the impertinent offer of their gratuitous services? Perhaps you will say, because the hospital surgeons do so. But permit me to add, that this case is utterly distinct from the other. Independently of the pupils' fees to the medical officers of hospitals, these institutions are voluntary charities; while the workhouses are established by law, in which the sick paupers are entitled by the same law to good and sufficient medical attendance, which their guardians are compelled to provide.

Our profession has had to complain of the bitter insult of being put up to Dutch auction. But what better can be expected, when that profession is still more cruel to itself? Does any one imagine the possibility of putting up military, naval, legal, or clerical situations to Dutch auction? Oh no: simply because those professions never have, and never will sanction or allow any thing of the kind.

If a clergyman of our church were to rush to offer his gratuitous services in competition with the respectable paid chaplains of our prisons or workhouses, his insolence would be forthwith put down, after a proper representation, by the bishop.

I beg you, sir, to reflect a moment on what would be the consequence, if inexperienced young lawyers were allowed by the offer of gratuitous or cheap services to usurp the justice seat. No doubt, like young aspirants for doctoring paupers, they might get very pretty practice. But would such a state of things be just to the prisoners, to the public, or to the law profession?

I should like to know whether our pro-

fession can for ever sustain the shocks of such competition. Is it not enough, that it has been assailed from without, but that we must be adding to the misery by a sharp competition to do the business of the rich for nothing, when there is so much real merit struggling for the means of mere existence among the members of our medical colleges?

Your obedient servant,

PHILIATRUS.

THE LONDON MEDICAL GAZETTE,

BEING A
WEEKLY JOURNAL

OF
Medicine and the Collateral Sciences.

FRIDAY, JANUARY 24, 1845.

REPORTS OF CASES TREATED IN UNIVERSITY COLLEGE HOSPITAL.

By H. FEARNSIDE, M.B.

Gradual failure of the health for a considerable period, and existence of various symptoms indicating derangement of the cerebral circulation; sudden loss of consciousness, without paralysis, continuing in a greater or less degree for sixty hours; cessation of this state, and development of a neuralgic affection of the loins and lower extremities. Rapid and successful treatment by counter-irritation, iodide of potassium, and generous diet.

JOHN LOVEGROVE, æt. 43, admitted into University College Hospital under Dr. Taylor, May 5, 1843. A tall, and very spare man, of dark complexion; he considers himself tolerably strong, and has generally enjoyed good health; his habits of life are regular; his occupation is that of a tailor, and for the last eight or nine years he has been in the habit of working very hard, not unfrequently from early in the morning until near midnight. For some time past he has found much difficulty in maintaining himself and his family in any degree of comfort; he has consequently been obliged to undergo various privations, and not rarely he has been unable to obtain a sufficiency of wholesome food. He has been a resident in London since the age of 14 years: his father died of dropsy, his mother of old age; neither of them was subject to rheumatism; his brothers and sisters all died when young. He has hitherto suffered but little from any severe illness; an attack of scarlatina, and an injury to his leg having been the sole causes of his being confined to his bed, during the whole period to which his recollection extends; he has, however, had several severe catarrhs, especially during the last two years, and has

on several occasions observed that his expectoration was tinged with blood. For several months past his sight and strength have been failing; about four months ago he had what he calls a "liver attack," suffering much from pain in the lower part of the right side, but he was not jaundiced; about two months ago he caught a very severe cold, from being obliged to part with some of his clothing; he has of late suffered much from mental anxiety, his appetite and spirits have failed, he has frequently had headache, his temper became irritable, and loud noises, or a bright light, were unpleasant.

After the continuance of the above-mentioned symptoms for about three weeks, during which he had undergone much physical exertion, as well as suffered much mental disquietude, he had an attack, of which the following account is furnished conjointly by himself and his wife. On the night of April 23d, shortly after getting into bed, he experienced severe pain in the fore part of the head; the greater part of the surface of the body became hot, but his feet were cold; soon afterwards a profuse general perspiration broke out upon him; he then became sick and vomited; this was succeeded by severe rigors, his whole body being in a state of tremor for some time. Of his state, and of the events which transpired during the ensuing sixty hours, he has no recollection, but his wife informs us that he laid almost motionless in bed, without any stertor or oppression of breathing, and apparently asleep; on being roused, he replied rationally to any questions which might be proposed to him, but very soon relapsed into his previous condition, and in the course of an hour or two he would have completely forgotten the circumstance; he had sufficient consciousness to be sensible to the calls of nature, but refused to take any nourishment. This state appears to have suddenly ceased on the ensuing Wednesday morning, and the first sensation he experienced was one of intense hunger; he afterwards felt exceedingly lan-

gaid, and much disposed to sleep; the senses of sight and hearing were peculiarly sensitive to impressions; he had pain in the head, was thirsty, and there was considerable heat of the body generally, and of the head in particular. On the following day, the pain in the head abated, but he was seized with a violent lancinating pain in the loins, shooting thence to the hips, and down the thighs, the inner parts of which felt benumbed. This pain has continued, and has been so severe as to confine him to bed, but in other respects he has improved, and the febrile symptoms have ceased. When the lumbar pain first sprung up, he suffered from a frequent desire to void the contents of his bladder, and a smarting, scalding sensation in micturition; he had also some pain in defecation; both of these symptoms, however, have since become less annoying. The medical treatment which he has undergone has consisted principally in the administration of purgatives, and the application of cold lotions to the head, and a blister to the nape of the neck.

State upon admission.—The surface of the body is warm; he complains much of languor and debility, and has some suspicion that the right side of the body is weaker than the opposite one, but the difference is by no means obvious. There is considerable tenderness upon pressure on each side of the sacrum, especially near its upper part, and the pain extends from this situation down the posterior (and slightly inner) surface of each leg to the ankle. Pressure upon the sacrum occasions a sudden darting pain in the legs, which also occurs at intervals spontaneously.

He has some headache, and complains of a sense of weight over the eyebrows; he occasionally has the sensation of flashes of light passing before his eyes, and tinnitus aurium; he sleeps well, but feels giddy on first rising; his memory is somewhat impaired; his spirits have been better since than previously to the attack, but his sight has failed considerably.

The chest is of a peculiar elongated form, as if it had been subjected to lateral compression. The ribs are very obliquely placed, with a direction from behind downwards and forwards, and they meet the costal cartilages by an obtuse and prominent angle; the sternum being sunk in a depression. The cartilages of the false ribs of the two sides are approximated so as almost to meet, and there is about a hand's breadth only between the lower border of the tenth rib and the umbilicus. One of the patient's children has a similarly shaped thorax.

He has no cough, dyspnoea, or pain about the chest; the right side appears to move less than the left one in breathing; number of respirations, 18 per minute.

Percussion upon the clavicle elicits a clear sound upon both sides of the chest, but more so upon the right than the left; under the right clavicle the sound is duller and the vocal fremitus stronger than beneath the left one. The *respiration* is bronchial below the right clavicle, and the inspiratory murmur loud and rough below the left one. The sound on percussion is dull over both supra-scapular regions, the dullness extending lower upon the right than upon the left side; the breath sound is somewhat bronchial in the same situations, especially upon the right side, and during expiration. There is nothing abnormal about the sounds or impulse of the heart; pulse 80, soft, and compressible.

The tongue is moist and rather furred in the centre; he has some thirst, no nausea or sickness; appetite good; bowels open; urine pale, sp. gr. 1009, slightly acid, unaffected by heat or nitric acid. There is no enlargement of the liver or spleen.

Treatment and subsequent progress of the case.—The patient was directed to take four grains of Iodide of Potassium three times daily, and was placed upon full diet. For some days he continued to complain of heaviness of the head, especially in the occipital region, indistinct and perverted vision, as well as of the pain in the lower extremities, which he compared to that which would be occasioned by the passage of an electric shock through the parts, occurring in paroxysms which often succeeded each other with great frequency for ten or fifteen minutes, and then subsiding would leave him at rest for an hour or more. This pain was especially induced by motion; its removal appeared to be promoted by the use of a strong ammoniacal liniment, with which friction was made over its seat; and this, with the gradual increase in the dose of the Iodide of Potassium to eight grains, constituted the whole remedial treatment; under the employment of which the patient progressively improved, so that he was able to leave the hospital in a little more than a fortnight after his admission. The Iodide of Potassium appeared to produce no obvious effects on the system, unless a copious night perspiration which the patient experienced during his stay in the hospital was connected with it. The appetite continued exceedingly good, the bowels acted regularly, and the sp. gr. of the urine rose from 1010 to 1015, but on several occasions it appeared to contain an excess of the salts of phosphoric acid.

Although at the period of his discharge, the more prominent symptoms were either removed, or greatly mitigated, those referable to the organs of special sense persisted; vision remained less distinct, and hearing less acute, than they had been previously to the attack.

Remarks.—The *diagnosis* in this case was rendered less precise than it would have been, from the fact that a considerable interval had elapsed between the date of the patient's attack, and that of his admission into the hospital. It appears from the history that for some months his health had been failing; he had been subjected to privation and much mental anxiety, had lived poorly and worked hard, his employment being sedentary, and necessitating a stooping position of the body. It was not, however, until the evening of April 23d that these causes issued in the production of any marked result. The affection, an account of which is detailed above, was clearly one of the nervous system, and appears to have had its origin in cerebral congestion. It bears a close analogy to the group of symptoms described by M. Andral* as characterising what he describes as the second form of this pathological state, viz. sudden loss of consciousness, with or without preceding giddiness, but without any distinct paralysis. This may continue from some minutes, up to thirty hours, and is succeeded by rapid recovery without any lesion of sensation or motion, although there may be, for a few days, a little difficulty in the performance of the functions of relative life.

This view is confirmed by the nature of many of the symptoms of which the patient complained when he first came under our observation. The headache, somnolence, slight impairment of the intellectual faculties, and hebetude of some of the senses, are what might be expected after prolonged disorder of the cerebral circulation. To these may be added another symptom to which the patient made reference more than once, a sense of weight and oppression in the back of the head; a situation corresponding to the great confluence of venous blood in the torcular Herophili.

The tenderness on pressure over the sacrum, and the pains in the legs, appear to have been a neuralgic affection. It was not articular; the patient had no predisposition to rheumatism, and had not been exposed to the usual causes of that disease. On the other hand, the suddenness with which it sprung up, its severe paroxysmal character, its following the course of the nerves, and the fact that pressure upon the sacrum occasioned lancinating pain in the legs, strongly support the former supposition. Again, before and at the period of the patient's admission, several of the symptoms of what has been designated "irritation" of the lower part of the spinal cord were present, such as frequent and painful micturition and defecation.* Moreover the previous habits and mode of life of the patient were

well calculated for the development of undue nervous sensibility.

The signs obtained by a physical examination of the patient's chest, the diminished motion of the right side, the dulness on percussion over the right infra-clavian space, and both supra-spinous fossæ, the increased vocal fremitus under the right clavicle, and the bronchial respiration heard over the same part, pointed unequivocally to the existence of some condensation in the upper parts of the lungs, and of the right one in particular. From the fact that the patient had been failing in health for some time, that he had on different occasions expectorated blood, and from other circumstances connected with the history of the case, there appeared equally little reason to doubt that this was owing to the deposition of tuberculous matter in the situations just indicated. It is worthy of remark that during the time that the patient was under observation, there was an entire absence of any general symptoms leading to the inference that the lungs were diseased.

The *prognosis* in this case cannot be considered as very favourable; under a continuance of the same causes which led to the first attack, a second and aggravated one may be anticipated; or if placed in more favourable circumstances, and should the tendency to cerebral disease be kept in obedience, there remains the pulmonary affection, which it is but too probable will continue to advance.

But little need be said relative to the *treatment* of this case, as the history furnishes the best comment upon it. Under a liberal allowance of food, counter-irritation upon the spine and legs, and the internal administration of Iodide of Potassium, the patient rapidly improved, and was sufficiently well to leave the hospital in seventeen days after his admission.

ON THE PRESENT STATE OF THERAPEUTICAL INQUIRY.

BY JAMES ARNOTT, M.D.

Physician to the Brighton Dispensary.

[Continued from page 481.]

AFTER the illustrations which have been given of the principal sources of therapeutical knowledge, it remains to inquire what influence theory has had as respects our knowledge of remedies. If the explanation of the morbid condition rest solely on mechanical or chemical principles, the appropriate

* The urine also had the characters usually seen in nervous affections; it was pale, watery, of low specific gravity, and often contained an excess of the phosphates.

remedy may, as has been admitted, originate from such explanation; but what is called the theory of medicine, or pathology, and which consists principally in an explanation of the elementary forms of disease, such as irritation, congestion, inflammation, tubercle, spasm, &c. usually implies, a consideration of the laws of vitality, and the functions of the nervous system. In this sense it would be an easier task to shew the mischief theory has occasioned than to collect the instances of its direct advantage. Nor can the important disclosures of morbid anatomy, with regard to the existence and analogy of diseases, be regarded as more than part of the foundation on which theory of this description has been built*.

Theory has had a higher character than it deserves in this respect, from improvements having been attributed to it which really proceeded from other sources. We have an instance of this in a remedy which has been already adverted to. The opinion is still commonly entertained that the discovery of artificial respiration as a means of recovery, or even resuscitation, from the effect of narcotic poisons, originated from theory. It is true that a plausible theory may have drawn public attention to the subject (and this is one of the advantages of theory), but the discovery proceeded from no such source.

* As the removal of the continued operation of the cause of a disease is frequently a very important part of the treatment, the great progress that has been made in our knowledge of etiology must be considered a direct improvement of therapeutics, arising from the correct induction of facts, and the advance of physical sciences. This knowledge is about to be turned to practical account as respects drainage and ventilation; and other benefits of a similar description might be obtained by the interposition of government. The spreading of contagion, for instance, could often be prevented by a little more care on the part of the medical attendant. The plan of the self-supporting dispensary, properly carried out, would, by making it the interest of the medical man to prevent disease, be well calculated to effect this. For criminal negligence, gross ignorance, or intentional concealment, as respects contagious disease, there ought to be an adequate penalty.

The great advance that has been made in our knowledge of the means of warding off the causes of disease is alone sufficient to confer dignity on medical science. But in apportioning honour for discoveries in prophylactics, the claims of several persons, unconnected with the profession of medicine, must not be forgotten. We are indebted to Captain Cook for showing how the health of seamen may be preserved; and a similar obligation will, I have no doubt, be hereafter acknowledged to Mr. Chadwick for his valuable researches relating to the health of the poorer classes in towns.

It was probably the analogy between the state produced by narcotic poisons and the state of suspended animation from drowning, which led Mr. Whately to the employment of artificial respiration in the remarkable case communicated by Dr. William Hunter to the Medical Society of London, and recorded in the sixth volume of their "Medical Observations and Enquiries." But because Mr. Whately was not an "authority," as has been remarked in the first paragraph of this paper, as he had no connexion with any celebrated school, and because, perhaps, his important facts were not supported by plausible theory, the practice of which he had thus most clearly shown the efficacy, was not adopted, and, it may be, his statement was not generally believed. Twenty years afterwards, and when the splendid discoveries of Bichat on the relations between the functions of the brain and heart had drawn the attention of the profession to the subject, the inquiry was revived by Sir Benjamin Brodie, and his theory of the *modus operandi* of the remedy being more in accordance with modern notions than that advanced by Mr. Whately, the truth became established*.

But theory has other and greater uses than drawing attention to important facts. Until more facts are accumulated, and the legitimate deductions from them are made, it would be a very difficult matter to conduct the treatment of any case of disease without more or less assistance from theory. Those practitioners who value themselves as being purely "practical," and who may think that, as respects themselves, there is no necessity for inculcating a closer

* The history of this invention is a curious illustration of what I have said respecting the discouragements of therapeutical inquiry in the first paragraph of this paper. So little was known of Whately's proceedings in the matter, notwithstanding the celebrity of the person who communicated his facts to the Medical Society, and the reputation of their printed Transactions, that the credit of the discovery was generally given to Sir Benjamin Brodie, who, at that time at least, was only more secure of public attention by the accident of his connection with the school founded by the illustrious man on whose recommendation probably Mr. Whately's paper was communicated to the public; and, in consequence of Sir Benjamin's credit on this account, more weight was attached than might otherwise have been the case to the inferences drawn from his unfortunate experiments regarding animal heat. They were unfortunate, as, by giving a wrong bent to inquiries on the subject, they have deprived this country, where it originated, of the glory of completing the chemical theory of the source of animal heat.

alliance between medicine and the Baconian philosophy, are nevertheless much indebted to theory; not only for maintaining the confidence of their patients by its suggesting plausible explanations, but for enabling themselves consistently to continue the administration of drugs. They may, indeed, regard with contempt the great and fashionable theories of the day, but they seldom employ a medicine without some reference to a theory of either ancient or modern date; for it has ever been held to be essential to the recommendation of a remedy not only to give experimental proof of its value, but to assign a plausible explanation of its action.

Again, the apologists of theory maintain that without its assistance the important facts in therapeutics could not be kept in connection so as to be remembered by the practitioner; it is called the string by which the bundle of facts are kept together. But if some connecting means is essential, it were surely better to impress the important particulars on the memory by collecting them in metrical lines to be got by heart, than by the aid of a false theory. It is, indeed, a wonder that the industrious class of writers who profess to cater for short memories, should not have, long ago, substituted some such plan for their vade-mecums on diagnostics, toxicology, and other departments of medicine abounding in facts which have little natural connexion.

Theory, as springing from so many collateral sciences, has been supposed to confer dignity upon medicine, and to distinguish more certainly the well educated practitioner from the mere empiric, a character which it has owed to the greater study its acquisition implies. But were theory altogether banished from medicine, the difficulty of the student would be increased, instead of being lessened. Extensive observation and induction of facts must then be its substitutes, and far greater powers of mind are required for these than were required for spinning the ingenious theories that were formerly so much in fashion. Physiology is, however, now fortunately so far advanced as to render the construction of plausible hypothesis a more difficult task than it used to be; and it is more likely, on this account, to demolish

ancient speculations of this kind than build up new ones.

What is wanted, then, for the progress of therapeutics is a collection of well authenticated facts relating to the cure of disease. If different practices are in use for the cure of a particular disease, let a sufficient number of instances, where the morbid conditions are nearly similar, be chosen for comparison, and let that be afterwards preferred which is thus proved to be the best. It is possible, however, that two different practices may be equally good, or, at least, that they may appear so to our imperfect perception.

To return to an illustration already given: inflammation of certain parts may be relieved either by removing the pressure made on them by fasciæ or the integuments, in the manner described; or, singular as it may appear, by increasing that pressure. Both practices have been in use for the cure of phlegmonous erysipelas, and other analogous diseases; and were the pressure perfectly equable, such as that which is produced by a fluid, it might be difficult to determine, even in perfectly similar cases, which practice is best. The treatment of gout and rheumatism by pressure would probably have been more successful, had a better mode of producing it been adopted. In applying this remedy to such cases, not only has the pressure been unequal, but the regulation of the temperature of the part has been neglected. Both of these errors were avoided in a case lately under my care. A lady had been affected, for several months, with a diffused pain and tenderness in the forearm, preventing the use of it, and causing sleeplessness at night. The affection had been termed, and probably correctly, a diffused chronic inflammation of the cellular membrane. It had resisted a variety of remedies, amongst which a bandage, applied with the greatest care, had held a prominent place. I wished to have an apparatus of Macintosh cloth prepared, for applying equal pressure; but as the greatest anxiety was expressed that something should be done without delay, I substituted the following expedient:—Two tin collars, or bracelets, were procured, just large enough to slip over the arm; and a circular piece being cut out of both ends of two large ox-

bladders, they were firmly tied upon these collars, one over the other. Two small pieces of brass tube were tied into the outer bladder, for the purpose of conveying liquid to and from the space between them; and in order that this space should not be wider than was requisite, as well as for the purpose of giving strength, the bladders were covered with a piece of cloth, in the form of a sleeve, which was likewise tied at both ends to the collars. The temperature of the water which passed in a slow current through the space between the bladders was at first that of the body, but was gradually reduced to as low a degree as the patient could bear with comfort. The degree of pressure was regulated by the same criterion; it was generally that produced by keeping the end of the waste pipe about a foot above the arm. In less than two days so much relief was experienced as to render the continued application of the apparatus unnecessary. There was, towards the end, an oozing of water from the bladders, which made it necessary to rest the arm in a sort of trough; but this inconvenience would not be experienced in the use of a more lasting material*.

If, in inflammation, the capillaries are in a dilated and weakened state, as pathology teaches, it would necessarily follow, that were a degree of pressure sufficient to prevent this dilatation applied to the foot in gout as soon as the premonitory symptoms made their appearance, its inflammation would be prevented, and experience of the curative agency of equal pressure would corroborate this opinion. Such a practice would, indeed, be forbidden by a fashionable theory of this disease; but may not those who require so very high a degree of action in the extremities, as the means adopted by the *vis medicatrix* for eliminating the poison, find elsewhere, and by artificial means, an adequate substitute for it? Besides, does not the administration of colchicum, the favourite remedy for gout, oppose the same theoretical views? Let us select hernia for another exam-

ple, as the principle of surgical therapeutics is more intelligible than the *modus operandi* of medicines. What confusion still exists in the preliminary treatment of strangulated hernia! A dozen different plans present themselves to the practitioner's attention, and he is puzzled which to prefer, how to combine them, how long to persist in the use of each, or to what extent, or to fulfil what indication, he is to carry it. As respects the last question, is he, for instance, by the use of the enema, to endeavour only to evacuate the lower bowel; or, by distending that part of the intestine which is immediately under the strangulating ring, in the manner I have lately suggested, and as has been practised in supposed intussusception, is he to endeavour to withdraw the strangulated portion?

Where every practice hitherto adopted in particular diseases has proved unavailing, recourse must be had to the great sources of discovery which we have noticed. These will, at this advanced stage of the art, generally supersede the necessity of the strictly empirical use of remedies. Yet while the conscientious practitioner is thus restrained from empiricism, he need not shut his eyes upon the experiments which are daily being made upon their dupes by rash and unprincipled men. If the persons who, from credulity or despair, are willing to become the subjects of such experiment, fail in obtaining advantage for themselves, an accurate observation of the effects of such practices may, by promoting medical science, be of the greatest importance to their fellow men. Had homœopathy been in fashion fifty years ago, and its effects been closely watched by competent observers, there can be no doubt that the destructive use of mercury in syphilis would much sooner have been abandoned. Charlatans had, indeed, long advertised their skill in curing this disease without mercury; and there can be now no doubt of the correctness of their assertion; but, unhappily, the regular practitioner would not stoop to examine the results of their practice.

Homœopathy, hydropathy, and mesmerism, or the means of strongly influencing the imagination and bringing the hysteric diathesis into play, are all great systems of experiment;

* Some observations on the construction of an apparatus for the external application of fluid pressure may be found in the appendix to the writer's "Treatise on Strictures of the Urethra," p. 217.

but as those who practise them are men in whose assertions the profession do not confide, they are nearly useless as respects any scientific purpose*. These practices are condemned by the profession; but do the indiscriminate courses of mercury, iodine, colchicum, or of purgatives, either artificial or as they exist in mineral waters, prescribed by regular or at least licensed medical practitioners, deserve a much higher character? They are equally systems of experiment, and the only advantage they have over the others is, that the experiments have occasionally been made by men of some education, and who may be able not only to profit by them themselves, but to place the results before the profession in a credible form.

For the observation of therapeutical facts arising in the ordinary practice of medicine, our larger hospitals are the best field. That more advantage has not been obtained from the opportunities which these establishments afford, arises, I conceive, from two causes. The first is, that the persons connected with them, and who may be fully competent for the task, being otherwise much occupied, have not had the leisure to furnish sufficiently comprehensive reports of the progress of diseases under the effects of remedies; the second, that the reporters being usually either the persons themselves who prescribe the treatment, or persons under the influence of the prescribers, as their teachers or patrons, their reports have not that stamp of truth which is essential for their utility. The practitioner who conducts the treatment is too apt to be himself deceived; he only looks for, or duly observes, what is consonant to his own opinions; and his reports, from omitting other circumstances, and attaching undue importance to these, deceive others. How otherwise, than by such

self-deception, can we account for the fact of the extreme rarity with which particular remedies or lines of practice commended by authors of unimpeachable veracity, the commendation being supported by the details of numerous cases, have been found to answer the expectations of others who have on such testimony tried them? To suppose that these authors suppressed the cases unfavourable to their views would be to accuse them of dishonesty, quite as much as to suppose that they had knowingly distorted or omitted important circumstances in the cases which they have related. Reporters should not only, by their acquirements and leisure, be able to afford complete and accurate descriptions, but, by their being unprejudiced and disinterested, assurance must be given that the facts related are not distorted. Were methodical reports of every important case falling under their observation, to be furnished by a body of well-educated men and philosophical observers attached to the public hospitals, but who had no connection either as pupils, assistants, or dependents, with the medical officers of the hospitals, how valuable would such information be for instituting comparisons between different modes of practice! Were the reports of men of this character, in whom the profession would have full confidence, drawn up on a uniform plan, so as to admit of easy comparison, and either published or sent to some central institution, where they could be consulted at leisure by writers of monographs, or persons investigating particular diseases, how rapidly would useful medical knowledge advance! Every student would then, it may be said, have the door of every hospital thrown open to him; for excepting the expression of the countenances of the patients (and ere long the daguerreotype will perhaps transfer this to the case-book), every circumstance of importance, and some which he himself might omit to notice, would be vividly brought before him by the graphic report.

* If Sir James Graham persist in granting impunity to quacks, it is to be hoped that he will at least insist on their congregating their patients in hospitals under proper inspection, where, for the benefit of science, their experiments may be witnessed. And it is to be hoped that he will, at the same time, devise some better plan for distinguishing the licensed from the unlicensed practitioners than registration; seeing that, in consequence of the extraordinary proceedings of the Council of the College of which the greater part of the former are members, in relation to their newly-granted charter, not a tithe of these will be willing, by the act of registration, to acknowledge their connection with it.

The boards or councils of medical colleges or corporations, did they consist of men respected and confided in by the profession at large, might dictate a certain form of report, and even usefully appropriate part of their funds to defray the expenses incurred by the institution of comparisons between

the several practices, or the drawing up of results in a tabular form*. It is unnecessary, however, to enter upon the subject of the best mode of drawing up medical reports. Of late years this has been well considered, and correct conclusions respecting it have probably been arrived at; but it may not be so needless to intimate, that in all that respects the effects of remedies which require some skill, or attention at least, in their application, notice should be taken whether due skill or attention has been exhibited. For example, in the application of ointments or lotions to diseased canals, it is of much importance as respects the remedial effect that every part of the diseased surface should be subjected to the remedy; but this is rarely done, and then only by accident. Solid substances may often be applied either in the form of, or as a coating to, a bongie, of a size suited to the diameter of the canal; liquids by being made to distend a permeable tube of the same shape. I have succeeded, by attention to this, in speedily curing disease that had long resisted a variety of applications made in the usual imperfect manner.

The different results following a difference in the mode of bleeding, which have already been adverted to, is another illustration of this point. Nor are these confined to general bleeding; even the temporary abstraction of blood from the circulation which is effected by dry cupping requires that the mode in which it has been accomplished, or the extent to which it has been carried, should be minutely mentioned. Dry cupping may, from the number of cups applied, be either the mere placebo generally applied, or form an efficient means of revulsion of great value where (as in many cases of apoplexy and congestion of the brain) it is important to remove a certain quan-

tity of blood temporarily from the circulation, and yet not reduce the powers of nature beyond that degree which may be necessary for her curative agency. By the adoption of an expedient which I have recommended, of sticking a bit of lint or other bibulous substance to the bottom of a common beer glass by sealing-wax, and afterwards dropping a little strong spirit upon it, for the rarefaction of the air by combustion, an opportunity is afforded to the most inexpert operator, and in almost any situation of emergency, of covering the body with cupping-glasses, and without the usual pernicious delay. Such a plan would, in some respects, be preferable to using the large cupping vessels for enclosing the limbs, lately introduced into practice under the auspices of the French Academy of Sciences; and it might be assisted by another old expedient, lately revived, of detaining the blood in the limbs by encircling them with bandages*.

While the editors of medical journals would find reports, such as have been described, very acceptable to their readers, there would be no want of applicants for the office of hospital reporter or recorder. The opportunity for gaining knowledge, if not zeal for science, would be a sufficient inducement; and any temptation which the indolent and unqualified might have to hold the office, on account merely of its being a means of promoting their interests by the reputation it might confer, would be restrained by the obligation they would be under of furnishing complete and methodical reports for public inspection. The patients in the hospitals would find a

* A board so constituted might, with great advantage to medical science, adopt the practice of the French Academy of sciences, of furnishing the profession, from time to time, with reports upon new proposals in therapeutics, or alleged discoveries in science, submitted to their judgment. But for the encouragement of the French Academy, the general substitution in certain cases of a safer operation for lithotomy—a substitution which, though it originated, was neglected in this country—would probably not even as yet have taken place. The French appropriation of this improvement, however it may affect private interests, is of no importance as respects the great interests of humanity.

* Until very lately, the same effect was produced by the tourniquet in amputation; and even now, when an improved mode of compressing the artery is in use, there is often loss of blood from this operation sufficient to turn the scale against the patient's recovery. It may have been mainly to this cause, that the recent and lamented death after amputation of a highly promising surgeon of Brighton is to be attributed. There had been profuse hæmorrhage previously to the operation, rendering it of the greatest importance to prevent any further efflux of blood. Were the blood squeezed out of a limb by pressure methodically applied for this purpose, previously to amputation, so disastrous a result might be prevented; and there would then often be, proportionably, more blood in circulation after the operation than before it. Might not such a compression of the extremities and of the abdomen, so as to determine the blood to the upper cavities of the body, be of service in that class of cases for which the transfusion of blood has been recommended?

direct and immediate advantage in the attention of their attendants being often drawn by such reports to circumstances which they might otherwise overlook; and the medical officers, while they likewise would have an advantage from this, would not fear any criticism of the reporters, or any consequent loss of reputation, as adequate means would be resorted to, before their entering upon the office, to prevent any such dishonourable interference. With this precaution there might be great utility, from the recorder's expressing, in a separate form, his own opinion of the nature and suitable treatment of the diseases of which he reports the cases; an opinion which the medical officer who regulates the treatment might either coincide with or reject, according to his judgment.

Such a plan might perhaps, in many instances, and with some modifications, be advantageously substituted in private practice, for the present system of medical consultation. No practitioner will refuse assent to the proposition that another opinion, even in the commencement of any important case, would be highly satisfactory to him, whether it be confirmatory or emendatory of his own opinion, for every one must experience some anxiety under these circumstances; and as regards the patient, it may be of the greatest consequence—in the one case producing perhaps a greater decision in the line of treatment adopted, on which the patient's speedy recovery may depend; in the other, causing an alteration of treatment which may be absolutely requisite for the cure. Yet how rarely can such consultations be held! Their rarity, and the notorious fact that they are seldom had recourse to, unless great danger, either immediate or remote, be apprehended, often prevent the medical attendant proposing such a course, lest alarm should be created. Why medical consultations, as they are at present conducted, are not sought for in the earlier stages of disease, and why, when desired by the patient or his relations, they are sometimes resisted, it is needless to inquire; but were the person consulted to be restrained from all improper interference in the manner proposed as respects hospitals, and were he restricted to a mere verbal or written opinion expressed to the medical attendant, the

usual objections would not hold. There would, besides, be this advantage, that the medical men in consultation would have no inducement to make any pernicious compromise of opinions; the attendant on the case feeling himself perfectly at liberty, either entirely to adopt, or entirely to reject, the second opinion.

Besides the advantage to the profession generally, arising from their access to these complete and faithful reports of disease, it would follow, by the measure of increasing the number of offices at our hospitals, that a greater number of members of the profession would have the opportunity of benefitting by the direct observation of disease. It is a general fault in the present management of these institutions to appoint too small a number of medical officers—too small even for the duties required of them; those who obtain the appointments have their interests of course promoted by this arrangement, but those who are excluded, and who are often men of more merit and modesty than their successful competitors, are treated with injustice. The appointment of a body of reporters to each hospital would tend to rectify another and a very glaring defect in the present system. A fair opportunity of distinction would be afforded to the younger men in the profession, and their reports would furnish the best test which an impartial and competent committee of the governors (to whom the election of medical officers ought to be confided) could desire, to guide their choice on vacancies occurring amongst the prescribing medical officers. How desirable is it for the interests of the poor, and the character of the profession, that some such test should be adopted! For the interests of the poor; because able men would then be their medical advisers, instead of those incompetent persons whom mere good fortune and family connection so often thrust into such places; for the character of the profession, because an end would be put to the practice of distributing testimonials of character and scientific acquirement amongst a whole host of governors; testimonials in which, by the publication of their titles, &c. the interests of those who eulogize are frequently as much consulted as the interests of those on whom the eulogies are conferred; for (as we

have remarked on another occasion) the praises of pupils in testimonials, and the newspaper puffs of plasters, too often in this respect belong to the same category*.

One immense advantage of thus recording medical facts by impartial and talented observers, would be the cessation that would thence ensue of the pernicious influence of authority, than which nothing has more retarded the progress of medical science. It would become imperative on every practitioner to make himself acquainted with facts, and to draw his own conclusions from them. It could no longer happen that men, who from a variety of accidents may have acquired an authority with the profession, to which neither their talents nor their acquirements entitle them, would be permitted either to dictate objectionable practices of their own, or successfully to oppose the introduction of the better practices of others.

In the above remarks on the present state of therapeutical inquiry, I am well aware that the practical suggestions which I have introduced in connection with several of the illustrations, must have interrupted and perhaps enfeebled my argument; but I was unwilling to omit what may ultimately, when matured by my own observation, and the experience perhaps of others, prove of some avail. These suggestions are, besides, not only of what I deem the legitimate class, as being founded on analogy instead of hypothesis, and in so much may be reckoned as good illustrations of the several points, as the established practices from which they spring; but they all admit, with one or two exceptions, of

explanation upon intelligible physical principles. I trust, however, notwithstanding these digressions, that the main purpose of this essay, though a mere sketch, has been accomplished; namely, to shew, first, that therapeutics, the most important branch of the science of medicine, still continues, in spite of the great progress made in physiology and the other auxiliary sciences, in a deplorably low state; secondly, that as it is not so likely to be speedily removed from this state by the further cultivation of these, and the theories built upon them, as by observation of the effects of remedies, &c. on disease, and the discovery of analogies existing both amongst diseases and remedies, the investigations of zealous inquirers should not be so much confined to the auxiliary sciences, as at present; and lastly, that as the reports of medical observations have hitherto been of little avail, from the situation of the reporters, or certain influences affecting them, some alteration in this respect is necessary in order to insure the reports possessing that degree of impartiality and correctness which is essential to their utility.

INFLAMMATION OF THE LIVER.

To the Editor of the Medical Gazette.

SIR,

SHOULD the following case of inflammation of the convex surface of the liver, attended by a distinct physical sign, be deemed worthy a place in your valuable journal, its insertion would greatly oblige,

Your obedient servant,
JOHN L. PATERSON, M.D.

Paraibo, S.A., Aug. 1, 1844.

In the month of May, a free black, residing on a sugar plantation a couple of leagues out of town, came to consult me for various dyspeptic affections, from which his health had been suffering more or less during the antecedent six months. He was diagnosed to have granular disease of the liver, and was treated in accordance with such opinion; and during the next three weeks he said he felt his health rapidly improving. At the end of this time, however, he was obliged to make a journey inland of some 200 miles; and in the course of it was much ex-

* Fortunately for those whose motive in seeking such offices is to possess an extended opportunity of observation, the appointments to dispensaries, from the circumstance of their not possessing so much éclat with the public as hospitals, are more easily obtained, and often without the necessity of stooping so low as may be requisite for the acquisition of the appointments in hospitals. Yet, as sources of information to the physician, dispensaries have much the advantage over hospitals, not only as regards the number of cases seen, but in all that regards acute disease. Dr. Alison, who has had much experience as a physician, both to a dispensary and an hospital, states that "it has often happened to him to meet with more opportunities of observing and pointing out to pupils the power of blood-letting over inflammatory disease in a single forenoon of visitation of dispensary patients, than in a three months' course of clinical instruction in an hospital." (*Library of Medicine*, Vol. i. p. 100.)

posed to the conjoined influences of sun and rain. He felt immediately a renewal of his old complaints, and on his return home, felt himself worse than at any former period. Three days after his return, the following symptom, and for which alone the case is remarkable, made its appearance, and so much alarmed him, that he immediately came to town again to consult me. On placing the hand over the epigastric and the anterior part of the right hypochondriac regions, there was communicated to it a rubbing sensation, similar to that felt over the heart in certain cases of pericarditis, but in the present case much rougher and more distinct. On applying the stethoscope over the same parts, that same creaking-of-new-leather sound was heard as in pericarditis, but much more prolonged, louder, and coarser. Any opinion that might on the instant have suggested itself of the dependence of these symptoms on disease of the heart or the arterial system, a moment's examination was sufficient to dispel, showing them utterly unconnected with these, and dependent on, and synchronous with, the act of respiration; for on the patient's holding his breath they immediately disappeared.

The diagnosis made was, that there existed inflammation of the convex surface of the liver and its peritoneal investment, accompanied by an exudation of soft coagulable lymph, and that the symptoms above referred to arose from the motion of the diaphragm over such surface. This opinion seemed borne out by the following considerations:—1st. As already mentioned, on the patient's holding his breath, the symptoms were no longer discoverable. 2dly. They were much more distinct in the erect or sitting posture than in the recumbent; in which last, from the weight of the liver causing it to be more closely applied to the surface of the diaphragm, the motion and play of this muscle over it would be much diminished. And 3dly, the character of the sounds themselves; on inspiration we had a succession of smaller creaking sounds, from the gradual and continuous motion of the diaphragm over the surface of the liver; whereas, on expiration, we had one, or at most two, loud irregular tearing sounds, as if from the sudden lifting of any body out of a viscid gluey substance.

The left lobe of the liver was enlarged and irregular. In ten days the patient again returned, when the rubbing sensation and the sounds were alike almost imperceptible; but the irregularities on the enlarged left lobe existed the same.

I have thought it unnecessary to burden the case with a detail of the other symptoms, or the treatment.

Practising, as I do, in a district in which inflammation of the liver is an occurrence of more than ordinary frequency, I have had an opportunity, since making the above details, of observing the same symptoms, though in a much less marked degree, in another patient affected with acute hepatitis; and I can yet remember of having, in former stethoscopic examinations, been struck with various anomalous sounds in the lower part of the chest, for which I was at the time unable to account, but which I have since thought may be referred to the same cause.

DESCRIPTION OF A MODIFICATION OF THE SPHERICAL-HEADED CUTTER, FOR THE EXCISION OF CARIES.

By SAMUEL MACLEAN, Esq. M.R.C.S.L.

THE spherical-headed cutter, for the removal of caries from cavities in the teeth, which cannot be reached by other means, is now very generally used. Although, however, its utility is greatly increased, by the addition of a guide, which enables the operator to steady the pressure and regulate the direction, it is still very far from being a perfect instrument, as caries frequently occurs in situations which it either cannot reach at all, or where it cannot be effectively applied. We have, accordingly, much pleasure in laying before our readers the following description of a most ingenious and elegant modification of this instrument, by Mr. Maclean, which removes all the difficulties attending its use in its present form:—

The accompanying plate, which represents the instrument in its full size, gives a very clear idea of its construction. It consists of a guide formed of a piece of steel, fitted at one end into an ivory handle, and at the other hav-

ing a truly turned collar, in which the mandril (C D) moves freely in a circular direction, being prevented from falling out by a groove in its circumference (F, fig. 2), which engages with a steady-ing pin (at A, fig. 1). This mandril is

represented out of the collar, in fig. 2. The cutters (E) are put in at one end of the mandril, and secured as drills are secured in a drill-stock; and to the other end (D) of the mandril, is attached the driving-handle (G H), by

means of a very simple form of Hook's universal joint, which enables motion to be given to the mandril and contained cutter, when the directions of the cutter and driving-handle form a very acute angle. The driving-handle, in Mr. Maclean's instrument, consists of two parts (α η and κ η in figs. 1 and 2), is of steel, and hollow from ι to η , for the purpose of combining lightness and strength, and also to serve as a convenient case for cutters. At the end it contains a small cylinder, represented detached in fig. 4, the bottom of which serves as a bearing for the axis of the swivel-head (η), which terminates the handle. It is obvious that the part κ η may be used as a handle for the ordinary straight cutter.

It is unnecessary to point out to the professional reader the advantages resulting from this construction. The superior steadiness given by the rotation of cutter and mandril in the collar, and the power of communicating a rotatory movement to the cutter, when the driving-handle is almost parallel to the guide, render the instrument perfect in a mechanical point of view*.

THE FAT OF ANIMALS NOT AN ELEMENT OF RESPIRATION.

By GEO. KEMP, M.D. Cantab.

Fellow of the Cambridge Philosophical Society.

(For the Medical Gazette.)

In a paper "On the Theory of Respiration," which was published in a recent number of this journal, I made no allusion to an ingenious theory of Professor Liebig, that whilst certain parts of the nourishment of animals are capable of being converted into blood, other parts are conveyed to the lungs, for the purpose of being converted into carbonic acid, and thus materially assist the production of animal heat: the former he has denominated plastic elements; the latter, elements of respiration†.

As this view was supported by some most remarkable analogies (which more recent researches, however, prove to be mere accidental coincidences), it speedily gained ground, was adopted

by the highest authorities in France*, and is now taught in many† of our schools as an established truth. Under such circumstances, I was unwilling to enter upon the subject at the conclusion of a lengthy paper, wishing to submit a succinct and decisive proof, but, at the same time, one independent of any peculiar views which I may have adopted, that the doctrine is untenable, and contrary to facts which are universally allowed to be amongst the most incontrovertible in physiology.

The most important bodies arranged by Professor Liebig as elements of respiration, are fat, starch, gum, cane, grape, and milk sugar. With reference to the latter of these, starch, gum, &c. the formula of the chyle, which I have deduced from the analyses of Marcet and Macaire, distinctly proves, that no bodies expressed by formulæ lying between the limits $C_{12} H_8 O_8$ and $C_{12} H_{14} O_{14}$, enter the system at all as such, or before undergoing certain changes in their composition, which, in the present state of our knowledge, we can only refer to the agency of the bile‡. It will also be seen that the fat, $C_{12} H_{16} O$, does not, without assimilation, enter the thoracic duct; but I would not by any means rest upon such a proof, when we possess one of a far more satisfactory nature.

The universal result of inquiries into the amount of oxygen consumed in respiration is§, that "the air once respired is diminished in volume;" and although the amount has been differently stated, as varying from 1-122d to 1-10th of the whole, it has never been observed to exceed 1-10th; the mean of all observations being only 1-24th. My deductions, in the paper on respiration, give 1-13th; but it is evident, from the very nature of the case, it must constantly vary. Now by the term "element of respiration," as applied to fat, can only be understood, that the carbon and hydrogen of the fat are converted into carbonic acid and water by the agency of the oxygen

* "The object of my observations was to leave no doubt of the physiological importance of the fat of animal bodies, as regards the process of respiration. In this view M. Dumas and Bous-singault agree with me."—*Ibid.* p. 310.

† Graham's Elements of Chemistry, p. 1017.

‡ This remark applies, of course, to the normal healthy performance of the digestive and assimilative process.

§ Müller's Physiology, p. 378.

* Dublin Journal of Medical Science, Jan. 1845.

† Liebig's Animal Chemistry, page 96.

contained in the atmospheric air inspired. The point, then, to be determined is, how much oxygen is required for this purpose? And how do the results of the hypothesis agree with the facts of observation? The formula, then, $C_{12}H_{10}O$, evidently requires an addition of 33 equivalents of oxygen, to obtain 12 equivalents of carbonic acid and 10 equivalents of water; but, so far as the oxygen is concerned, only that portion re-appears, as appreciable in volume, which has combined with the carbon; the portion which has combined with the hydrogen is practically lost. What relation, then, does this last portion bear to the whole amount inspired? Of the 33 equivalents consumed, 24 only, as seen above, combine with the carbon, leaving a loss of 9 equivalents of oxygen, which is nearly *three times the maximum* ever observed. The fat, therefore, cannot be considered as taking any important share in respiration.

In a former paper I have shewn, in a different manner, that the bile of animals is unsuitable for the purpose alluded to; but the subject is capable of numerical proof. Thus $C_{48}H_{42}NO_{13}$, in its ultimate disintegration, would first lose 3 equivalents of hydrogen, and all its nitrogen, to form ammonia; and then require $(48 \times 2 + 39)$, or 135 equivalents of oxygen, to oxidize its carbon and hydrogen; but 13 equivalents of oxygen are contained in the substance itself, which reduces the extraneous oxygen to 122 equivalents, of which only 96 combine with the carbon, and consequently 26 disappear as water; but 26 : 122 as 1 : 4.69; and thus the quantity of oxygen disappearing is more than *twice the maximum* loss ever observed.

It is not necessary to take up room with shewing, that even a small portion of either fat or the bile would involve conclusions more or less opposed to accurate observations; for the case put by Professor Liebig, and constantly repeated, is, that these bodies take a very *appreciable* share in respiration, or, as he expresses himself on the bile, are "the most important substances employed in the respiration." (Animal Chemistry, p. 158.)

In considering the respiratory function as consisting essentially in the act of eliminating effete matters, I thought

to have satisfactorily established the mutual compensative actions of the lungs and kidneys. It also appeared to be fairly proved, that the loss of oxygen inspired is referable to the quantity of hydrogen oxidized; but I was not at that time aware of the remarkable confirmation afforded to those views by the agricultural researches of Boussingault.

This kind of evidence will readily be admitted as extremely valuable, those researches having been undertaken with a totally different object. I must, however, reserve the subject for another occasion, as its importance requires more than the brief sketch to which I should necessarily confine myself in this paper.

A superficial view of the foregoing paper would lead to the opinion, that the point is only proved in one particular case, as omnivorous animals alone have been alluded to. With reference to carnivorous animals, the point is at once decided, as, under normal circumstances, they produce little or no fat; and the very large quantity of urea which they secrete amply accounts for the excess of oxygen inspired over that which re-appears in the form of carbonic acid. As it regards graminivorous animals, the researches of Boussingault, which are alluded to above, prove that the loss of oxygen in the horse amounts only to 1-31st part of the whole inspired: in the stall-fed milch cow, to 1-34th; but, as seen above, on the hypothesis that the fat is an element of respiration, the loss of oxygen should amount to one-third, or about ten times the maximum observed; and these cases of graminivorous animals are the ones specially adduced by Professor Liebig as proofs of his theory. The intimate connection of the amount of oxygen lost, and the form in which the azotised portion of effete matters is eliminated by the kidneys, is also very evident. The carnivorous animal, secreting a large amount of urea, sustains a loss of oxygen in respiration of at least one-fifth of the volume inspired: an omnivorous animal, secreting urea and uric acid (the urea being ten times less than in carnivorous animals), a loss of one-tenth; the horse, secreting benzoic acid and ammonia, 1-31th; and the cow, secret-

ing a body allied to hippuric acid, with excess of oxygen, only 1-34th. There is hardly a point in physiology, depending on this kind of evidence, that admits of such an accumulation of proof.

Douglas, Jan. 11, 1845.

NAPHTHA IN PHTHISIS.

To the Editor of the Medical Gazette.

SIR,

I HAVE watched with much interest the treatment of many persons labouring under phthisis pulmonalis by means of naphtha, but lament to state, that they have all gone "to that undiscovered country from whose bourn no traveller returns." Now I am induced to think that the above fact may be rationally accounted for, inasmuch as Dr. Hocken makes the following statement in the last number of your excellent journal:—"Till recently I feel convinced that scarcely any one has tried the *genuine medicinal naphtha*." The doctor has pointed out a place where the real article can be procured, and by so doing has conferred an inestimable boon on suffering humanity, provided it shall prove as efficacious in other hands as in his. He mentions in the same paper, that the plan of evacuating the contents of the chest, as a cure for consumption, was first recommended by Dr. Barry, of Dublin. I imagine that Dr. Last, about the year 1769, must have caught his ideas respecting a somewhat analogous treatment of dropsy from the same quarter. He observes, "I have been at a great deal of pains and trouble, and made many experiments, in order to find a radical cure for this disease, that should be at once safe, cheap, and easy. My first invention was a pump; by means of which, fixed in the belly of the patient, I meant to pump out the dropsical humour as you would water out of the hold of a ship. Threescore and eleven people died under the operation." He eventually abandoned this as impracticable, and his next experiment "was called the soaking operation, which was contrived thus: I made the patient swallow a piece of sponge fastened to a string, which, going down his throat into his stomach, I let lie there till I had absorbed or soaked up the watery humours, and then drew it up again, with all its contents; repeat-

ing the operation till I had left the body as dry as an empty decanter." This plan, though not so unsuccessful as the other, was after some trials relinquished.—I remain, sir,

AN OLD PRACTITIONER.

Paddington, Jan. 12, 1845.

THE RELATIONS OF THE PHYSICIAN.

(FROM THE GERMAN OF PROFESSOR HUFELAND.)

To the Editor of the Medical Gazette.

SIR,

IN a late number of your journal is a very sensible letter from your correspondent L., accompanied with a specimen of "*German Ideal Physiology*," from a work by Carus. I fully agree with your correspondent as to the additional interest which is imparted to your journal by the occasional insertion of extracts from the works of Foreign authors, and it will be your duty to select with judgment from the extracts supplied by your contributors, such papers as will tend to the honour and improvement of the profession.

I feel persuaded that the "*Specimen*," (also from the German,) I here enclose, will meet with the universal approbation of all your readers.

It is indeed a specimen of German literature, containing sentiments so sound, and so practical, as to find an echo in every well-constituted mind. It is from the pen of the venerable Hufeland, who, having devoted his energies to the improvement of the Practice and Literature of Medicine, for upwards of half a century, bequeathed to posterity his "*Enchiridion Medicum*," a depositary into which he casts the final results of his long experience.

I am sir, &c.

H*.

To live for others is the Physician's vocation. He must be ever ready to sacrifice his repose, advantages, and comforts; yea, even higher considera-

[* Our correspondent ought to have informed us that what follows is transcribed, with a few verbal alterations and omissions, from the edition in English of Hufeland's *Enchiridion*, published at New York, by C. Bruchhausen and Dr. Alison, a work which we had the pleasure of noticing some short time ago. The matter is good, however; and in consideration of Hufeland's *Enchiridion* not being generally accessible, we present it to our readers.]—ED. GAZ.]

tions, to the end of saving the life and health of his fellow-men. The healing art is therefore something sublime, and really divine; for its duties coincide with the first and most sacred laws of religion and philanthropy; and require resignation, and an elevation of mind, far above worldly desires. To improve his mind, to sacrifice his person for the public good, and to disseminate good around him, as much as lies in his power, is what he aims at. His professional duties, therefore, will always beautifully harmonize with his conviction and principles, and, so to say, flow from them. What he ought to do, he does with pleasure; and the consequence will be, the highest happiness of man, a consonance of external and internal life. Woe to the physician, who makes honour with men, or money, the end of his efforts! He will be a continual contradiction to himself and his duties; he will curse a vocation which does not reward, because he knows not true reward. This simple view embodies the whole *moral*, or *policy*, so called, of the physician. Policy!—an improper word; for nowhere more than in the medical profession do we see it exemplified, that the best and only policy is that which emanates from an honest and sensitive man. The fundamental rule for all the relations of a physician is:

“Regulate all your actions in a manner that the highest end of your vocation, which is saving life, restoring health, and relieving the sufferings of humanity, be attained as far as possible.”

This rule must ever be present in our mind; it will always direct us to the right point, and guide us safely in the most complicated cases.

From this point let us now consider and regulate the duties of a Physician. They are threefold; towards the sick, towards the public, and towards his colleagues.

A. Relation to the Sick.

The Physician, in exercise of his art, must regard only man, and make no difference between rich and poor, high or low.

He who suffers most, or is in the greatest danger, has a privilege above all others, whatever be their station or condition in society. I pity the Physician who appreciates his patients according to rank or fortune; he knows

not the finest reward of a Physician. What is a handful of gold, compared with the tears of gratitude shed by the poor? The rich man, by his compensation, frequently thinks himself entitled to be ungrateful, and to undervalue the services rendered; but how often is the Physician the sole friend left to the poor in distress! Like an angel of consolation, he appears to him, and raises the vanishing hopes by the interest he takes, and by his art he pours new life into his veins.

In medical treatment, the Physician must exercise his *greatest attention*, *accuracy*, and *conscientiousness*. He must not proceed superficially, but with research and knowledge. He must not consider the patient as a means, but always as an end. Seldom, it is true, can the faults of the Physician be brought before, and punished by a tribunal, but the most certain and the most formidable tribunal is waiting for him—Conscience—where no subterfuge, no palliation, can guard him; where nothing will absolve him but a pure and guiltless mind, and the conviction of having done all within his power and knowledge towards saving his patient. Though he may have learned through improved knowledge, subsequently acquired, that he might have done more and better, he may regret his former deficiency, but not feel remorse; for, at that time, he did all he was capable of performing. He must, however, remember that neither levity, his own ease, or any personal consideration, must lead him to neglect his duties, for then the internal Judge will not remain silent. Such cases will, sooner or later, meet with adequate punishment from tormenting reproaches.

But skill and art alone are not sufficient; he must be particularly mindful of his conduct. It is this which recommends him to the public, and creates confidence and admittance; for the generality of people are incompetent of pronouncing on his science; it is, then, natural for them to take their measure of his ability from the measure of his conduct. By force of conduct alone, a Physician of very modest talents can become the favourite of the public; and, without it, the most skilful medical man remains unnoticed and unappreciated. Of his external appearance, also, he must not be regardless; it should comport with the

dignity of his station, and the importance of his duties. The main feature of his conduct should be aptitude to create confidence; friendly, with dignity; decent, without affectation; gay, but not ludicrous; serious, when he ought to give importance to his subject; and his words complaisant and indulgent in all insignificant matters, but firm while executing important measures, and sustaining the pronounced sentence; sympathizing and cordial, and a sound regard for religion, and its consolation; neither taciturn nor loquacious; much less a messenger of news; but, devoting his whole attention to the sick, noticing every circumstance, careful in the examination of the patient; observing even those around him; neither eccentric or vulgar; neither coxcomb, nor pedant; but holding in the middle, even in all things; especially not passionate and angry, but calm and circumspect; for a quiet and sober sense creates confidence. It is a great fault, common to young practitioners, that they strive to create a sensation, whether it be by the newest fashion of dress, or science, or by paradoxes and singularities, or even by charlatanism. A most important point for attaining the public confidence, but rather too much neglected by our young practitioners, is keeping a journal of cases. When the noise of the day has terminated, and the silence of evening invites to reflection, then the Physician may devote a few hours of calm contemplation to his patients; write down the most important points in the history of a malady, the alterations which have occurred, his remarks and ideas on the origin and treatment of the disease, the remedies prescribed, and reconsider the whole maturely. No evening must pass without paying this last duty to his patients, and thereby adding the keystone to his work. Here, in the silence of night, many a thing will appear to him in quite a different light, than during the day; revelations and inspirations will come over him, such as cannot find birth in the distractions of busy day. Only in this period, when internal life awakens, also can this subject enter into internal life; and only now will it receive true interest and reflection. For that alone which affects and fills our mind, which accompanies us always, even unconsciously, is ours; and solely penetrated

by such an object, we may hope to become perfect in it, and to arrive at new discoveries. The great Newton once was asked, how he had come to his extraordinary discoveries: "I always thought of them," was his reply, "simple but certainly, all embracing." The same is true in regard to visiting the sick. When shall we cease to place confidence in the mere presence of the Physician, and to esteem his care by the number of his visits? Alas! the head cannot keep pace with the feet, as Zimmermann has well remarked. Such mere corporeal presence, and looking on, however often repeated, will not promote a cure; and, properly speaking, amounts to nothing more than rendering honours, paying one's respects to the disease, according to its rank. A visit must be made with deliberation, a collected mind, and be of sufficient duration. The Physician must not be present in body only, but in mind; and must direct his whole attention to his patient, and study him. It is only such visits that will answer the purpose sought. They will result in a double advantage to the Physician; firstly, in convincing the patient of the interest which he takes in him, and thereby gaining his confidence; secondly, in creating that reciprocity of feeling, and familiarity, which permits of a deep insight into the nature of the case; in short, to use an expression of the magnetizers, "place the sick person *en rapport* with the Physician," certainly quite in a particular state of mind; one which admits of particularisation, and a deep insight into the "inward man," teaches us to form more correct feelings and ideas, regarding the sufferings of nature, and her wants, from art, and gives thoughts which strike us the more forcibly since they arise directly from the patient. One such visit is worth more than many made in haste. Too many visits in chronic cases, since they render the patient too common to our senses, may blunt the keenness of our perception, and obstruct our vision; as the saying is, "we cannot see the forest for the trees." I have experienced in such cases, that an interruption of the usual visits, for several days, will enable us to gain a new view of the subject, and to bring phenomena to light, which, heretofore, have escaped our observation. It must, however, be

remarked here, on account of young Physicians, who, through delicacy, confine their visits to too small a number, that in general frequent visits are more requisite, since they enable one to arrive at a more perfect knowledge of the disease, and also preserve the confidence of the patient. Too frequent and unnecessary visits have to be avoided, for they give useless anxiety to the patient, and expose the Physician to be suspected of interested motives. The office of the Physician is not confined to curing diseases; it behoves him, as a duty, to prolong life, and relieve suffering, as maladies pronounced incurable. How much, then, at fault are they who grow disgusted, or lazy, and neglect or forsake a patient when there is no prospect of cure? The interest of the artist, it is true, may be annihilated; but humanity must persist and increase. Verily, the unfortunate who labours under torturing pain, distress, and despair, is still more entitled to our commiseration, than he to whom the prospect of recovery lessens all suffering. It is an act of pity, natural to every generous heart, in such cases, to make life tolerable, to raise dying hope, and to bring consolation at least, where there is no salvation. Moreover, we are too short-sighted, to be capable of always deciding, with certainty, that help is not possible. In the course of a disease, favourable internal revolutions may take place, an external influence may operate, and give a new turn, or give to art opportunity for successful interference. Yea, I consider it as one of the most important rules of practice, never to give up hope. Hope generates ideas, elevates the mind to new views and new endeavours, and can render impossibility possible. He who has given up hope has given up reflection, upon which apathy and paralysis of the mind follow; and the sick must invariably die, because he who has been called to his assistance is already dead. Even in the stage of dying, the Physician ought not to forsake the sick; even then he may become a benefactor, and, if he cannot save, may at least relieve departing life.

The *art of writing prescriptions* is very important, and worthy of more attention than is generally bestowed upon it. *It is the last result of the*

whole examination of the Physician, and the only perpetual document of his genius, and which has even legal authority bearing for or against him.

How readily a little fault committed in a prescription, an error in writing, may decide the fate of the patient, and the Physician's reputation! therefore, it should always be done with a mind most concentrated; and it ought to be an invariable rule with every Physician to peruse every prescription after it is written. Whenever it is possible, without detriment to the main end, the practitioner must always prefer the cheaper to the more expensive remedies. It is indeed cruel to neglect this consideration, in the case of indigent persons, and to take away the means of living, in saving their lives. In this respect he can become a real benefactor to his patients, if he regards their financial circumstances not only with benevolence but with delicacy. I will only refer to one means, by which the expenses of cure may be exceedingly diminished without the *appearance of gratuitous* medication; it is, to make an agreement with an apothecary of charitable mind, to this effect, that he will not charge profit on receipts marked with a concerted sign, by which expedient, those who are really poor, but do not wish to seem so—the bashful poor, may be saved considerable expense. In this way we may succour the indigent, without offending the feelings: to do this, is really to benefit.

Dangerous remedies ought never to pass into the hands of the patient; at least, not in such quantities as to endanger life. It is a horrible sight to see phials of an ounce, or half an ounce of opium, in the sick room. If an accident happens in such a case, the fault always lies with the Physician. No honest practitioner will sell, nor even allow to patients nostrums; for how can he judge of things which he does not know himself?

B. *Relation to the Public.*

To no one is *public opinion* so important as to the Physician. He is the man of the people, in the true sense; the voice of the people decides what shall be his true station. He must, therefore, be most anxious to win reputation, and not unmindful of the means proper for that purpose. It is in vain

to boast of being above public opinion, and not to care for it. The pride of a wise man is, to accomplish his end in the most correct manner. The principal end of a Physician is curing; the more opportunity he can find for practising it, the more completely will he attain that end, and become a benefactor to mankind. Now that depends mainly on the good opinion of the community, and consequently it devolves upon the Physician, as a duty, to make efforts for acquiring and establishing himself in it.

Extraordinary talents, and striking success, it is true, can, so to say, force public opinion, and raise a Physician, even in spite of general dislike. But these are rare exceptions. The common course is this—the young practitioner has gradually to raise a public sentiment in his favour, by which the public may be encouraged to commit to him the highest earthly good—life and health.

The principal means for attaining that end are (besides careful and conscientious attendance on his patient), unshaken probity, regularity of habits, temperance, prudent conduct, modesty, discretion in all his utterances and judgments, precaution in the selection of his company, attention not alone to essentials, but also to appearances. The Physician must never forget he is more observed than other men. He belongs to the community, and every one arrogates to himself the right to judge him. He is of no party; he belongs to all. *Popularity* is his element, and freedom of mind, and of all political relations, his noblest prerogative. He must therefore carefully avoid joining a party. On the contrary, he may congratulate himself that his vocation permits, even obliges him, to take no notice of parties, and be only mere man.

Wit, and a satirical disposition, are dangerous gifts to a practitioner. In no man are they so prejudicial and incompatible with the nature of his vocation, as in the person to whom one has to expose himself in all his nakedness, and has to disclose infirmities and secrets which no body else is destined to learn.

How many have contracted irreconcilable enemies by a single pun! a real injury is more readily pardoned

than mockery. Secresy is one of the first and indispensable qualities of a Physician; for, by his vocation, he learns the most important secrets, and takes the place of a confessor; the happiness not only of single men, but of whole families, lies at his discretion; and it would be an act of baseness to betray confidence, or abuse it intentionally. He is to avoid being, or even appearing, indiscreet; therefore he must speak as little as possible of other patients; answer laconically, and indefinitely, questions asked about others; and, least of all, go into particulars and narratives of domestic life: above all, a practitioner should not be reputed a gamester, a tippler, or a libertine, for these habits are in direct contradiction with his profession, and infallibly will take from him the confidence of the public. He must not appear too desirous of gain; it debases the Physician and his art, deters the poor from applying to him, and takes away that which is worth more than all riches—good repute.

ANALYSES AND NOTICES OF BOOKS.

“L'auteur se tue à allonger ce que le lecteur se tue à abrégér.”—D'ALEMBERT.

Outlines of Military Surgery. By Sir GEORGE BALLINGALL, M.D. F.R.S.E. Regius Professor of Military Surgery in the University of Edinburgh, &c. &c.

INDEPENDENTLY of the national importance of this branch of the profession, the position the author holds in the University of Edinburgh, and the circumstance of a third edition being called for, entitle these *Outlines* to due consideration.

Military surgery includes much more than the mere treatment of surgical diseases, which, indeed, forms but a small part of the duty of an army medical officer. It comprises every thing relating to the prevention as well as the cure of disease—in a word, the extensive subject of Military Hygiène. The topics to be discussed under this head are, “Recruiting, bounty, pay, pensions, and rewards; barracks, transports, clothing, personal cleanliness; duties and exercise of soldiers;

schools and regimental libraries; military discipline and punishments; habits of soldiers, comprehending virtues and vices; the constitution of the medical department, and the duties of the medical staff, both general and regimental; military hospitals; moral treatment of the sick; the compilation of numerical returns of the sick, and the plan of drawing up reports both special and general; proceedings of boards, sick certificates, &c., together with the general principles of military statistics and medical topography; and lastly, instructions to young medical officers respecting their general conduct, especially in regard to their superiors, their equals, inferiors, and patients*." Taking this as a tolerably correct enumeration of the subjects which should be discussed in a work on Military Surgery, we must come to the conclusion that our author has fallen short of the object at which he aimed. Many of the preceding topics are not mentioned at all, and others so casually, as to convey no practical information to students ignorant of all that relates to a military life. Such a work should contain a body of instructions, addressed to young men studying for the department and to junior officers, relative to their duties in the army, and should "embrace, in a general way, all that body of information which every medical officer who has been long in the service acquires in a greater or less degree, but frequently not until he has committed blunders that might have been obviated had he been earlier or better instructed."

The surgical part of the work under review is in general good; but the portion which treats of these military and hygienic topics, we regret to say, is very defective; less than one-fifth of the volume is devoted to them, which is certainly too little, considering their extent and importance. At page 60 of the Outlines it is stated, on the authority of Sir D. Stewart, "that the 92d regiment lost more officers and men in four months from the *climate* of Jamaica, than by the hand of the enemy in an active war of twenty-two years, in the progress of which it was twenty-six times in battle."

The professor seems to have met with similar objections from other

quarters, for he says, "an opinion has been expressed that more of the work should be occupied with the medical, and less with the surgical department of the course." With the first part of this opinion we do not quite coincide, but we would wish to see much more devoted to the topics mentioned above. The diseases of tropical climates form part of every course of practice of medicine in the present day, and the treatment of gun-shot wounds, &c. is discussed by every lecturer on surgery, while the numerous works on practical surgery, of acknowledged merit, at moderate prices, and of bulk adapted for a military man's library, render this portion of the Outlines much less necessary than when the first edition was brought out. But as a reason for this preference shewn to surgery, he says, "I find that this is the department of the course which proves most interesting to that important part of my audience, consisting of gentlemen returning from foreign service, to refresh their memories, or to renovate their knowledge at the schools of medicine." Now we are far from underrating the importance of officers thus brushing off the rust from their memories, or making themselves acquainted with the improvements that have taken place during their absence; but we would suggest that they might do so quite as well in the lecture-rooms of the professors of practice of medicine and surgery; while it is only from the professor of military surgery that the student can expect to acquire information on the subject of his *special* duties as an army medical officer. We are sure none can look back to the commencement of their career in the army without feeling how much a knowledge of these would have contributed to their comfort and usefulness. While we give Sir George Ballingall every credit for the kindly feeling towards old officers by which he is actuated, in thus devoting so much of his time to them, we cannot but think he would effect a greater and more permanent good by confining his attention more to the rearing of efficient recruits for the department.

While we thus dissent from our author's plan of treating his subject, we do not undervalue the surgical portion of the work. Great pains seem to have been taken to bring up the information on the various subjects to the latest date.

* Edin. Med. and Surg. Journal, vol. xliv.

In reviewing a third edition, we cannot of course be expected to go much into detail; but we would notice an article on the "proportion of sick in armies," which is, we believe, a new feature in the work. This is a point of great importance to be able to estimate, that a General may know, out of a given number, how many are likely to take the field, and that he may be provided with an adequate medical staff; and it is essential, to enable medical officers to make the necessary hospital arrangements, and lay in a sufficient supply of medicines and stores. Our author has quoted the opinions of several distinguished writers on this subject, and has given the numbers admitted into hospital, and who died, as stated by Sir John Pringle to have occurred in Germany, in Flanders, and in this country, and by Sir James McGrigor in the peninsular army; but as the strength of the different armies is not given, these figures are of comparatively little value. Although it is of consequence to be able to estimate the number likely to be admitted into hospital under given circumstances, it is much more so to know the proportion constantly non-effective from sickness; and on this point we think our author might have advantageously bestowed a little more space and labour. Vaidy, in his *Hygiène Militaire*, estimates the probable proportion in a healthy garrison at 5 per cent., or in a campaign at not less than 10 per cent., independent of any rencontre with the enemy; but it is not stated on what data this calculation is founded. Sir J. Pringle states, that at the end of the campaign in Germany, the sick in hospital were to the men in health as 3 to 13, or 23 per cent. It is remarkable that this is, to a fraction, the same as the proportion ascertained by Mr. Edmonds to have been constantly sick in the peninsular army, averaging 64,227 strong, between Dec. 1810 and May 1813. This is all the precise information contained in the *Outlines* on this point. The following (which for the sake of space we have arranged in a tabular form), though a mere contribution to the statistics of this important subject, will serve to show that our author might have rendered the article in question more complete. (See p. 550.)

We think Sir George might have

greatly improved his *Outlines*, and particularly the section on the diseases of troops on foreign stations, by drawing more liberally from the valuable statistical reports of the navy and army*, care being taken to condense the information as much as possible. The value of a numerical over a loose or vague statement is indeed very great, and it has the advantage of occupying little space (especially when given in a tabular form), and bringing the principal facts before the eye at once.

Having recently inserted in this journal two articles on the physical and moral effects of military punishments, we looked to our author's remarks on that subject with some curiosity, to see whether he had endeavoured to supply to the young medical officer the want of specific official instructions on this responsible duty. We regret to say that he has not; the only advice given is to abstain from "any idle or pertinacious display of his own consequence in a case where he may fancy his authority paramount to that of the commanding officer." Nothing is said of the necessity for a careful examination of the prisoner prior to signing the certificate of his fitness to undergo punishment, which is laid before the court; nor of the propriety of a re-examination before the flogging, lest disease should in the meantime have been lighted up. We find no mention of those symptoms which would lead us to place the man under observation for a few days before sanctioning the infliction, such as quick pulse, furred tongue, burning skin, &c.; nor of the schemes adopted by some men to get "taken down," and the means of detecting and frustrating such attempts. The last, it should be remembered, must be the work of a few seconds; if the man is really unable to take any more of his punishment, every minute he is kept tied up may be productive of serious injury, while, if taken down without sufficient cause,

* By the way, our author talks of the *Military Statistical Reports* as the joint labour of Colonel Tulloch and Deputy Inspector-General Marshall. By the Queen's Regulations for the Army, Deputy Inspectors and Lieutenant-Colonels rank with each other according to the date of their respective commissions. On what principle, then, does he give to a Lieutenant-Colonel of 31st May, 1844 (we love to be precise), precedence of a Deputy Inspector of 22d July, 1830? thus reversing her Majesty's orders.

discipline suffers, and the surgeon is looked on by the men themselves as a soft fellow, under whom they may with impunity try any tricks of malingering they think fit. We must again express our regret that the junior medical officers are still left without a sufficient guide in regard to their duty on a punishment parade.

In conclusion, we must repeat our conviction, that while these Outlines are no doubt useful to the older officers, as a book of reference on points of surgery, they are not calculated to instruct students and junior officers, as yet unacquainted with the habits and condition of the men over whom they are expected to exercise a vigilant superintendence, in the important duties which devolve upon them. We would strongly advise our author to bring out

a work on Military Hygiene, for the use of such; and when another edition of his Outlines is required, he can adapt them more exclusively for the seniors, to whom at present they seem chiefly useful. We are aware that to do this will involve a large amount of time and labour; but we have no doubt that, if Sir George undertakes it, he will execute his task in such a manner as to reflect credit on himself and the University of Edinburgh.

Statistics of Recruiting in the Districts of Great Britain and Ireland, during the Year ending 31st March, 1844.
Compiled from the Annual Returns, by order of the Director-General.
Lithographed.

THE name of the compiler of this brochure is not given; but we presume the materials have been arranged under the superintendence of Dr. Gordon, professional secretary to the Director-

* Considerably understated—vide Report.

† This low ratio is chiefly attributable to a large portion of the Malta fencibles being married men.

‡ See Report on Troops in the United Kingdom.

\$ Strength not stated exclusive of *frontiers*.

General. It is much to be regretted that the compiler was not instructed to include the statistics of recruiting for a period of twenty or twenty-five years, instead of limiting his labours to one year. Besides, by confining his observations to the recruits inspected at the head-quarters of districts, and thereby excluding those who enlist at the head-quarters of regiments and depôts, no general deductions can be drawn in regard to the absolute number raised during a specific period of time, or in each of the several divisions of the United Kingdom. In the reports which may in future emanate from the medical department, we hope to see these omissions supplied, there being, it is presumed, no want of elementary materials.

The number of recruits medically inspected during the year ending 21st March, 1844, was 17,540, and the number rejected 6,026, or 34·6 per cent. An error appears to have crept into Table 3d, "shewing the native countries of recruits inspected," which table comprehends only 17,073 recruits, instead of 17,540. We regret the occurrence of this mistake the more, as we intended to make a few observations upon the relative disposition of the inhabitants of different divisions of the kingdom to enlist; but we are precluded from touching upon that subject at present. With reference, however, to this topic, we may simply state, that it appears by a Parliamentary return, that on the 1st January, 1840, there were the following number of English, Scotch, and Irish non-commissioned officers and privates in the British army:—

English, 47,394, or 34 per 10,000 of the population, according to the census of 1831.

Scotch, 13,388, or 51 per ditto.

Irish . 39,193, or 51 per ditto.

The relative proportion of recruits raised, &c. in the different districts, is appended to this notice.

Thus it appears that the range of the ratio of rejections in the above ten depôts or districts, is from 17·9 in the Cork district, to 48 per cent. in Edinburgh. The compiler states, that in the Leeds district the ratio of rejections is the highest; but this is a mistake, the Edinburgh district being 4·4 per cent. higher than Leeds. We have

remodelled this table of the relative proportions of recruits inspected, &c., as the form in which it has been drawn up is not well adapted for comparing the results of one district with another.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

RUMOURED CHANGES RELATIVE TO THE COLLEGE OF SURGEONS.

RUMOUR states that material changes are about to be introduced by the majority of the Council of the College of Surgeons, and that these changes are to be sanctioned by a supplementary charter. It is said to be in contemplation that all members now and for the future of ten or fifteen years' standing shall be created fellows; that gentlemen practising midwifery will be eligible to the Council; that the Court of Examiners will be partially composed of surgeon-aecoucheurs, and examinations in midwifery will form, for the future, an integral part of the surgical candidate's examination; that the fellows will take seniority in the order of their standing as members of the College, and be allowed to propose,

without reference to any list of precedence, any fit member as a candidate to fill up whatsoever vacancies occur*. We cannot tell upon what authority the above statement is based, or whence it originated. We would not for a moment suppose that any member of Council could have been wilfully guilty of a breach of confidence, or even permitted the slightest whisper to transpire of the private proceedings of the Board.

We need scarcely say we should hail with unfeigned satisfaction any proposed extension of the franchise, as being one of the most healing measures that could be adopted for allaying the discontent and heart-burnings now uttered in every quarter of the land. There can be no doubt that the Charter lately granted has been held to be a means of inflicting great injustice upon the members of that College; and this they feel in the most poignant manner. We have, therefore, no hesitation in affirming that, if the Council come generously forward and invite to the bond of *fellowship* every respectable member of a certain standing, irrespective of all other considerations, it will quench all prevailing animosities; it will tend to elevate the character of the profession, and effectually further the cause of reform. We have all along regarded the division or separation into two grades or classes as a very doubtful step. There can be only one degree in surgery, as in medicine. The endeavour to create two denominations of surgeons, although originating in most praiseworthy motives, appears like an anomaly in the annals of science.

In the event of such changes taking place as those above alluded to, we would submit to the Council the propriety of amplifying the course of examination. We are of opinion that

medicine, chemistry, *materia medica*, as well as midwifery, as suggested in the *Times* of Tuesday last, might be most judiciously appended. We should recommend farther, that the examination, so far as anatomy and chemistry are concerned, be made rigorously demonstrative, on the sound principle now introduced with respect to the examination for the fellowship. Let the candidate dissect, in the presence of the Court of Examiners, some region of the body; let him point out the relations and uses of the several parts the scalpel brings to light; let him apply the processes of chemical research to testing an animal fluid, or to the detection of poison. Thus the positive knowledge of the candidate will be accurately determined—thus an end will be put to the disgraceful system of *grinding*, which now prevails to such an unprecedented degree. The idle and dissolute will no longer be permitted to sully the ranks of an honourable profession; for none other than individuals fully qualified will be permitted to assume the title of surgeon. As a matter of course, the Society of Apothecaries would cease to exist; their occupation would be done. The novel project of incorporation of general practitioners would likewise speedily fall to the ground, and be forgotten. England would recognize as practitioners such, and such alone, as were members of a College of Physicians, or of a College of Surgeons.

The subject of midwifery has been heretofore a great stumbling-block to the corporate bodies of this metropolis. The practice of it is substantially in the hands of the members of the College of Surgeons; and, although there was a bye-law in the late Charter requiring a certificate of attendance on lectures in midwifery, no examinations were ever instituted touching the student's

* *Medical Times*, Jan. 18, 1845.

obstetrical knowledge; a department preposterously termed "ancillary to nature," by way of invidious distinction—as if medicine taken as a whole were ought else than ancillary to nature. It was the opinion of counsel that the apothecaries have no power by the Act of Parliament to examine in the art of midwifery, which is no respect comprised within the Act. We, therefore, cannot imagine that it would be in any wise derogatory for the Court of Examiners to bring this neglected subject within their pale, and submit to the candidate a question or two upon the functions of the uterus, just as they would upon the functions of the bladder. The two viscera are generally in juxtaposition. Assuredly, the management of the function of the uterus is as fairly a part of surgery as the management of the functions of the bladder, or of any other organ in the body. The great obstacle hitherto has been in viewing midwifery as a branch apart. It is no branch apart; it implies nothing more than the superintendence of a function of the human frame. You might as well, as Sir Charles M. Clark told the Committee of the Commons, "have a separate branch for lithotomy, which is the removal of a dead stone from the living body."

MOVEMENT IN THE PROFESSION.

THE Faculty of Physicians and Surgeons of Glasgow, a chartered body, that has exercised the privilege of examining and licensing general practitioners in medicine and surgery for upwards of two hundred years, held a *pro re nata* meeting within their hall, on the 9th ult. They cordially approve of the Bill as far as it provides a uniform standard of medical education and qualification. They agree to surrender all peculiar rights and privileges at present possessed by them, which may anywise interfere with the general interests of the profession, but claim the

same privileges proposed to be conferred upon other Royal Colleges. In giving their approbation to the formation of a Council of Health, they demand to have a representative from their body in the said Council. They acknowledge the favourable position they occupy in the Bill under the title of the Royal College of Physicians and Surgeons of Glasgow; but complain of the proposal to exclude them from the right and privilege of examining and granting licenses, as an act of injustice, not only to their Faculty, but to the Medical School of Glasgow, and to the City of Glasgow itself. They further recommend that a clause be introduced imposing a penalty upon any person, not merely for falsely pretending "that he is registered," but for falsely assuming any name or title implying that he is qualified to practise any branch of the healing art. The proposed fees for registration they deem too high. This Faculty are of opinion that proof of previous study ought to be required from the candidate for registration as a licentiate in medicine and surgery, as well as from the physician or surgeon; and that the age ought to bear reference to the period at which the candidate is entitled to be examined for his license.

A meeting of the medical profession of Ulverston and Lonsdale, North of the Sands, was convened on the 15th inst., W. F. D. Dickinson, Esq. in the chair. The circumstance of the legislature taking into consideration the state of the profession, and of the introduction of a bill into Parliament by Sir J. Graham for Medical Reform, was hailed with great satisfaction; but it was contended that great injury would accrue from a repeal of the Apothecaries' Act, unless some penal check and more ample security from empiricism were substituted. It was deemed desirable that a Council of Health be established, provided the interests of the general practitioner are duly represented therein; that annual registration be rendered compulsory; and that chemists and druggists be obliged to undergo an examination before a competent board, as to their proficiency in the knowledge of chemistry and pharmacy.

A petition has been forwarded by the

medical practitioners residing in the county of Hertford, praying for—uniformity of qualification and of fees required by the various examining Colleges throughout the kingdom; annual registration; equal right to practise; exclusion of unregistered persons from all public medical appointments, disqualification of such to give medical evidence, or grant certificates, and prevention, under a penalty for misdemeanour, from using or assuming any name or title implying that the party is a medical or surgical practitioner; protection to general practitioners against the practice of unregistered persons, equivalent to that afforded by the Act of 1815; a superintending Council, in which all classes shall be adequately represented. Lastly, all members of the College of Surgeons, at the time of granting the late charter, to be placed on a like footing, and to enjoy equal rights, titles, and privileges.

The following protest, we are informed, is now circulating in East Kent, and has already been numerously signed:—

“We, the undersigned members of the Royal College of Surgeons in London, residing in the Eastern Division of the County of Kent, desire to record our protest against the proceedings of the Council of the College, in relation to the new charter.

“We protest earnestly against being deprived of that equality of rank to which an equality of examination had entitled us; and we consider the offer of admission to the Fellowship upon examination and payment of fees, when it has been arbitrarily granted to others without either, to be adding insult to injustice.”

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Tuesday, January 14th, 1845.

MR. STANLEY, President, in the Chair.

Case of Aneurism of the Popliteal Artery, cured by Compression of the Femoral Artery. By EDWARD GREATREX, Esq. Surgeon, and W. T. C. ROBINSON, Esq. Assistant-Surgeon of the Coldstream Guards. (Communicated by the President.)

The patient, a private of the Coldstream Guards, 27 years of age, and previously

healthy, on the 2d of May, 1844, complained of pain and swelling behind the right knee. On examination, a large, irregularly-shaped aneurism was found filling up the popliteal space, strongly pulsating, and admitting of being partially emptied by pressure. A delay took place in proceeding to apply compression till the 18th of June, owing to the patient having been seized with acute laryngitis. An Italian tourniquet, with modifications in its construction, was then employed; but a relaxation in the treatment was soon required, from the patient being attacked with modified small-pox. On the 8th of July, the tumor having increased in size, the plan was adopted of screwing the pad down firmly upon the femoral artery, and leaving the patient the key, so that when the pain became intolerable he might relax the pressure by the instrument, and compress the artery higher up by his fingers. On the following day this method was found to have been successful, for the tumor was perfectly solid, and no pulsation or bellows sound was afterwards perceived. The compression was continued for nine days longer. When the instrument was removed, the femoral artery was distinctly felt to pulsate down to its entrance into the tendinous canal, and two arteries, about as large as crow quills, could be traced over the surface of the now hard and solid tumor. From this date the swelling gradually diminished; the patient began to walk about on the 9th of August, and he was dismissed from the hospital, to undertake light duty, on the 14th of November. He returned to full duty on the 12th December, which he has efficiently discharged to the present time.

Mr. B. Cooper inquired of the author of the paper whether he considered that his patient was safe.

Mr. Greatrex was of that opinion: the man had been on regular duty during the last six months.

Mr. Cooper had tried pressure in two cases of popliteal aneurism, but without the instrument and precautions adopted in the case before the Society. In the first of these cases, the patient, a laborious orange porter, was three years since admitted into Guy's Hospital for aneurism of the right popliteal artery, for which the femoral was tied with success. He suffered also from a small aneurismal tumor in the left popliteal space; and for the cure of this pressure was applied to the femoral artery by means of a compress and bandage, the compression being so regulated as to prevent the circulation through the vessel. The popliteal tumor became smaller, hard, and without pulsation; but in consequence of the healing process of the leg being protracted from

the formation of abscesses, the man was detained for a long period in the hospital, and when discharged was supposed to be entirely well. He returned, however, at the end of fourteen months, with the left popliteal tumor enlarged and pulsating; and it was thought advisable to secure the femoral vessel on that side. Whether the return of the aneurism was owing to absorption of the coagulum, or from the influence of an anastomosing vessel, he could not say, but such was the effect. In another case, in which he had operated on the opposite side a short time before, a man presented himself with aneurism of the popliteal artery; and for this pressure was applied for the space of six months, with the effect of producing an apparently perfect cure. Four months afterwards, however, the disease returned, and the artery on that side was ligatured, and a cure effected. In these two cases there was one point in which they resembled Mr. Greatrex's case, and that was the patency of the artery in communication with the swelling. Looking at this circumstance, so different to what occurred after securing the vessel above, and the return of the disease in his own cases, he viewed the result of Mr. Greatrex's case with some apprehension as to a perfect cure.

Mr. Greatrex said that compression was commenced in his case on the 18th of June, and by the 9th of July no pulsation could be felt in the tumor; the man was as strong on this leg as on the other.

Mr. Stanley had seen Mr. Greatrex's case; the disease certainly appeared to be cured. Points of importance, however, had been raised by Mr. Cooper. The operations by Mr. Liston, Mr. Cusack, and Mr. Houston, although at present successful, did not warrant us in concluding that we might trust to pressure alone in cases of this description. In answer to a question, Mr. Stanley replied that the circulation in the artery, in the case before the Society, was free, as it was also in two or three other cases that he had read.

Mr. Greatrex observed, that the mere freedom of circulation through the artery did not militate against the success of the mode he had employed, inasmuch as blood would in some cases flow to the aneurism even after ligature of the femoral.

Mr. Cooper thought that it would require twelve months from the operation to determine whether a cure was effected in cases treated by pressure.

Mr. Curling said that the mode of applying pressure pursued by Mr. Cooper was very different from that which was employed in the case under discussion. In one case the collateral circulation was unaffected; in the other it was interfered with. It was reasonable to expect a better result from the

one mode than from the other. In the treatment of popliteal aneurism by pressure, it was not necessary to completely obstruct the circulation through the femoral artery, as a mere retardation in the flow of blood would effect the formation of a coagulum in the tumor. We had no evidence at present of the condition of the artery after cure by pressure, but he expected that we should discover a firm coagulum in the sac, and a patent state of the vessel above.

Mr. Greatrex said, that the only peculiarity in the circulation in his case was, that on the affected side it was somewhat weaker than on the other.

Mr. Cooper knew that his mode of applying pressure was inferior to that pursued in the case before the Society. He considered it by no means proved that, in these cases, the mode of cure was different from that which obtained when the vessel was ligatured. The advocates of treatment by pressure considered it would do away with the necessity of all other operations.

Mr. Shaw recollected the case of a man in whom Sir C. Bell tied the femoral artery some years since, for popliteal aneurism. The pulsation of the tumor ceased for a short space of time, on the application of the ligature; but almost immediately returned, and continued for three days. It then ceased completely. Erysipelas attacked the limb, and six days after the operation the man died. An unusual distribution of the artery was found, for immediately below the giving off of the profunda the artery divided into two large branches, which again united into a common vessel immediately below the tendon of the triceps. Notwithstanding only one of these branches had been secured by the ligature, the blood in the tumor had coagulated and become firm, as the preparation of the case still shewed. This case illustrated the possibility of a coagulum being found in the sac of the aneurism, even though the channel of the blood was not completely interfered with.

Mr. Charles Hawkins detailed the case of a man who, some time since, was admitted into St. George's Hospital with a large aneurism at the upper part of the thigh. He would not consent to an operation; and as the tumor kept increasing in size, he eventually took to his bed, and there laid for the space of nine months, at the end of which time the tumor was very much diminished, and had since entirely disappeared. Sir B. Brodie had four or five years ago tied the external iliac, for aneurism in the thigh. The patient remained well for two years, when he again returned, with the tumor larger than ever. He shortly after died of disease of the lung; and it was then found that an unusually distributed

vessel communicated with the tumor, and reproduced the disease.

Mr. B. Cooper mentioned a case of popliteal aneurism, respecting which he had been consulted some years ago. The patient had six months previously been operated on by Mr. Wilson, of Manchester, an able and experienced surgeon. The cicatrix of the incision was still visible. The tumor had returned a few months after the operation. Mr. Cooper, with some difficulty, now tied the artery lower down. The pulsation in the tumor was instantly arrested, but returned in the space of ten minutes as forcibly as ever. As it was evident nothing further could be done by operation, the patient was placed in bed, blood taken from the arm, tartar emetic administered, and cold applied to the limb. On the fourth day pulsation had entirely ceased, and the patient continued well until his death, a short time since, at Milan, at which place he died of aneurism of the heart. In this case, no doubt, some anomalous distribution existed.

Mr. Stanley inquired what was the condition of the artery between the point of ligature and the aneurism, in the cases which Mr. Cooper had examined.

Mr. Cooper replied, that in four cases which he had seen, the vessel was a mere impervious cord.

Mr. Stanley had dissected two cases, one in which he had operated six years previously, the other had been operated on by Mr. Lawrence twelve months before death. In the first case, the femoral artery was found quite free from just below the ligature to the aneurism; and in the second case, it was free from the ligature to the middle of the ham. This, he believed, was generally the condition of the vessel, and was owing to the influence of the collateral circulation. In Mr. Lawrence's case the tumor was found to contain successive layers of solid fibrine.

Mr. Cæsar Hawkins thought as the tumor in Mr. Greatrex's case had decreased in size, and there had been no pulsation in it for a long period, that that gentleman was justified in considering it cured, except inasmuch as aneurism might return after any kind of operation. It was known to surgeons that aneurism did return at a very late period after operations for its cure. He had seen it return after seven years; and Sir A. Cooper related a case in which it was fifteen years before it re-appeared. In his, Mr. Hawkins', case, the man came back with a large popliteal aneurism, the result, doubtless, of some anastomosing vessel. Amputation was resorted to, but the man died a few hours after, and it was found that two large vessels came off from the ligatured vessel, one just below the tendon of the

triceps, the other communicated with the aneurism. Notwithstanding these anomalies, it was seven years before the sac of the aneurism refilled. If aneurism returned after cure by pressure, that means might again be resorted to. It was not necessary, as had been formerly supposed, to employ extreme pressure in these cases. It was now well known that moderate pressure, so as to retard, and not completely arrest, the circulation, was sufficient to produce a coagulum, and effect a cure. A case was at present under treatment by pressure in St. George's Hospital. In Mr. Weiss's instrument, the pad on the side towards the tumor was too flat; it would be more manageable if it were somewhat concave.

Dr. McDonnell had examined a case of aneurism in which Sir C. Bell had operated twenty years before. The artery above was obliterated.

Mr. Shaw recollected examining a case in which a man had died suddenly of aneurism of the heart, shortly after the femoral artery had been tied by Mr. Arnott for popliteal aneurism. A coagulum had formed in the tumor. The artery was pervious from an inch below the ligature to the aneurism.

A Visitor remarked, that the circumstance of death occurring from aneurism in some other part of the body after operation for this disease, seemed to indicate that there was something peculiar in the general arterial system in these cases.

The President said that in one of his cases death was the result of old age, in the other of aneurism of the heart.

On the Periodicity of Neuroses. By ISAAC PIDDUCK, M.D.

The case, related as a singular instance of neuralgic periodicity, was that of a girl, aged 14, in whom the catamenia had not appeared. Six years ago she was thrown out of a swing, and struck her head against a brick: pain in the forehead ensued, which lasted about a fortnight. The right hand then became clenched, and the headache ceased. The hand continued immoveably closed for three weeks, when it opened of its own accord, and the headache returned. The hand remained open, and she had the free use of it for three weeks, during which time she suffered from headache; it then closed, with the same relief as before.

From the time of the accident to August last, a period of six years, these alternations of closing and of opening of the hand, and of headache, have followed each other with perfect regularity.

When the author first saw the patient, the hand was closed, and a forcible attempt to open it gave her great pain in the head. She complained of tenderness along the cervical

vertebræ. One-fifteenth of a grain of strychnia was given three times a day, and mustard poultices to the spine; and, as the perspiration smelt very sour, an antacid diet was directed. Under this plan her health improved, and when the hand opened at the end of the last three weeks of its closure, she ceased to complain of the head. After this there was no return of closure of the hand, nor of headache, and she has continued perfectly well up to this time.

Sir G. Lefevre made some remarks with the view of showing that various affections frequently assumed the periodic character. He related the case of a young man in whom palpitation of the heart recurred every twenty-eight days. Nervous headache was frequently more severe in the morning, going altogether in the evening. It was necessary to attend to the condition of the mind in cases of nervous affections.

ON THE APPLICATION OF MESMERISM. TO SURGICAL OPERATIONS.

To the Editor of the Medical Gazette.

SIR,

In your number of Dec. 27th, you published a letter from a "Hospital-Surgeon," suggesting an experimental trial of the effects of mesmerism in deadening the sense of pain. Allow me to express my most cordial acquiescence in such a plan, and at the same time to suggest a further extension of this dispassionate inquiry into the merits of the case.

As mesmerists are fond of publishing an account of their wonderful sensations, we have by this time a tolerably large collection of *facts* scattered up and down in the newspapers, gazettes, &c. Let some one (excuse me, Mr. Editor) analyze these, and republish them in a tabular form: thus we shall learn what proportion of these wonderful people do such and such wonderful things.

As I am a sceptic, perhaps the *facts*, in my hands, would be as stubbornly opposed to display their true bearings, as are the subjects of mesmeric influence to give any manifestations in the presence of a man who does not believe in the truth of their exhibition before he has seen the show. So, praying to be excused for my own part, I will merely point out a few questions, the solution of which are deep in Democritus' well at present.

First, we find that patients in this state can see with their epigastrium. Now, can they see only with their epigastrium when naked, or may it be clothed? This would

be important to know, before introducing mesmerism into fashionable circles. Then, if it may be covered, what covering is the best? does flannel, or linen, or silk, do best? Is there ever a black spot on the object corresponding to a trowser button; or does the busk of the stays prevent perfect epigastric vision? How comes it that they can see, through a brick wall, any object hung up on the other side? Can different patients see different depths into the brick wall?

I shall tire you, Mr. Editor, with asking all these questions; but here am I, with my mouth open, aghast at the wonders around me! Must I believe them? They are all recorded by persons of most undoubted veracity. All, did I say? Let us have a column in these tables, which I want some one to make, stating the authority for each case, and a graduated scale of the veracity of each as settled by common consent. Let Miss Martineau and her little innocent stand at the head—say 100°. If you ask me why, I will tell you: from my own convictions of her honesty; because she would not tell any thing at the "Séance" till she was sure that all the village could bear her out in her statement. Of course she could have told it before, if she had chosen.

Let this case stand at the top of the list, then, in the order that is thought best; let us have Alexis and his brother, the Misses Okey, and all the rest.

This sight through brick walls troubles me, Mr. Editor, more than I can well tell; but I must ask you to set me right on another point. I do not at all understand this knowledge of past events. Alexis quite repudiated the idea of his mind being merely a reflection of that of his bear leader: he knew what had been done, and was doing elsewhere; so did Mr. Costello's case, who, however, did not scruple to avail himself of this reflection.

Pray let us have a column devoted to knowledge of past events, and mention, at the same time, as much as you can, about how much money the gentleman who asks the questions gets from the mesmerizer for so doing.

I should like to know about foresight; and whether, in any case, the bear leader has mesmerized his victim to know whether the speculation would answer; but I have taken up so much room, that I really am ashamed to ask any more of you; so believe me to remain, your

CONSTANT READER.

London, Jan. 14, 1845.

CONVERSAZIONE AT THE COLLEGE OF PHYSICIANS.

To the Editor of the Medical Gazette.

SIR,

SOME years back, when Sir Henry Halford was President, there were frequent Evening Meetings at the College of Physicians. These evenings brought together not only some of the most distinguished characters of the age, but sometimes Royalty, and frequently many of the nobility, and the heads of the Church and the Law. Besides such advantages, they made those not of the profession take an interest in it: they congregated together from the east to the west, and from the north to the south, all respectable grades of the medical profession, and created a most friendly and good feeling amongst them. The College of Physicians was a centre of attraction, and its meetings gave to those who lived at a great distance from one another, and on that account but seldom met, the opportunity of keeping up an old friendship, or interchanging sentiments both general and professional. So delightful were those evenings, that I hope, through the medium of your valuable journal, you will allow me to suggest a repetition of them. They might be of great utility in the present divided state of the profession, and restore that unanimity of good feeling which ought always to exist in so enlightened a body.—I am, sir,

Your obedient servant,

AMICUS.

January, 1845.

ST. MARYLEBONE INFIRMARY.

To the Editor of the Medical Gazette.

SIR,

YOUR correspondent, "Philatrus," in his letter on the St. Marylebone Infirmary, has made some very excellent remarks, in the justice of which I have no doubt but that all your readers will agree, upon the impropriety of medical men offering their services for gratuitous appointments. But, sir, your correspondent has been guilty of a gross act of injustice in endeavouring to lay the blame of this upon "*young aspirants for doctoring paupers*," under which head he would scarcely, I should think, class Drs. Mayo, Clendinning, and Harrison, or Mr. Stafford, the present officers of the Infirmary; or Drs. Marshall Hall, Hope, Sims, A. T. Thomson, Macreight, &c. who have either actually held, or at least competed for, and thus shown their anxiety to hold, gratuitous office at that Institution. Surely, if gentlemen of their age and position will do this, it is very unjust to

saddle the younger members of the profession with the opprobrium for the existing state of things.—I am, sir,

Your constant reader,

PHILOJUSTITIA.

January 18, 1845.

PURPURA HÆMORRHAGICA.

To the Editor of the Medical Gazette.

SIR,

IN perusing the very interesting case of Purpura Hæmorrhagica, related by Mr. Adams, in the Gazette of last week, I could not help thinking that the treatment there pursued was not the one agreeing with the pathology of the disease. On referring to the case, we see that the patient was bled from the arm, and that mercury in large doses was given: great debility and other formidable symptoms ensuing, stimulants were used; notwithstanding, the patient soon sank.

When we come to consider the nature of the symptoms in this well-marked case, we shall see that they denoted (as purpura in general does) a morbid and vitiated state of the blood; the blood, in fact, in this disease, has lost its vital part, if I may so say. Are those remedies, then, which only tend to impoverish the blood, to be used in this formidable state of things? Mr. Adams has told us that the blood was sizy, but its *coagulum loose*. This fact I think strongly contra-indicates the use of blood-letting and mercury, which especially tends to impoverish the blood and alter its constituent elements. *The large ribcices on the neck* shewed the deterioration of the blood and system altogether. The first case of the kind I ever saw was whilst I was in my apprenticeship; the symptoms were similar to the one related, but not quite so formidable—bleeding was here resorted to by the excellent and well-known practitioner I was with, and the patient sank rapidly, and I recollect well the practitioner's regret at the course he pursued. This case gave me a strong abhorrence of blood-letting, so invaluable a remedy in some diseases, and which I am afraid is cried down by some men who wish to change the treatment of medicine altogether. I believe that the treatment in purpura should be directed to the improving the condition of the blood. Therefore I would lay aside blood-letting and mercury (except particular circumstances indicate their use), and would recommend doses of sulphate of quinine, with the mineral acids from the first, with moderate purging.

At the latter stage of the disease, we should allow a liberal diet and the use of port wine.

I recollect well that Mr. Lawrence, who was called in to the case mentioned by me, used these after blood-letting was employed. In conclusion, I would impress the necessity of recollecting, in our treatment of this disease, that it is strictly one of the *blood*.

I am, sir,

Your obedient servant,

HENRY SMITH.

62, Great Russell Street,
Bloomsbury.

SOCIETY AND THE DOCTORS.

A SURGEON is sent for to attend a sick person—we now simply state a case occurring only the other day: in the discharge of his professional duties he is ready to go,—in the discharge of his duty to himself and family, he inquires who is to pay him; the reply to this reasonable, and, in a man who gets his livelihood by an arduous profession, natural inquiry, is, imprecations and abusive language; the surgeon declines to attend the patient, and the patient unfortunately dies, Society taking no more trouble than to order a coroner's inquest. The inquest is held; the surgeon states the facts above stated; he states, moreover, that he frequently was knocked up to attend paupers—the children of Society; to exercise his humanity, skill, and attention upon them, without getting a farthing; that he has himself knocked up the butcher, to get materials for making beef-tea for the patient, and was refused with butcherlike expressions; that he lived by his profession; that his time was his means of life; that, in this particular case, he was preparing to attend the patient, when he was revolted by the abuse of those who solicited his aid.

Society, represented by the coroner, or his deputy, we forget which, waxed exceedingly indignant. The poor practitioner was informed, with ludicrous gravity, "That if he got no money, he should have found sufficient recompense in the esteem of his fellow-men;" that he should be ready, at all hours of the day and night, to do Society's business, in the way of his profession, for nothing. "Humanity," said the coroner, "is a great thing." The jury, among whom might or might not have been the butcher who refused materials for beef-tea, became humane and benevolent, as it cost them nothing, and "fully concurred in the observations of the coroner."

Now, let us see whether in his conduct towards this poor medical man Society did not on this occasion exhibit himself a most unfeeling, as well as an impudent fellow.

A man determines to invest his time and money in obtaining the diploma of the College of Surgeons. Very well. Does

Society educate him for nothing? Does Society feed, clothe, and lodge him while walking the hospitals, attending lectures, or undergoing the disgusting details of the dissecting-room, for nothing? On the contrary, Society takes a thousand Protean shapes to extract money from the pockets of this very man, whom it victimizes afterwards for not running like a lamp-lighter to do its business gratis.

In the shape of a Professor, Society dives into the pockets of the student for fees for lectures, demonstrations, and hospital attendance; in the shape of a landlady and tradespeople it makes him pay through the nose for every thing he has, and, sometimes, for things he has not had; in the shape of a college it makes him pay for his diploma, before it admits him to examination.

Nor has Society done with him then.

When he sets up an establishment, Society expects that he will maintain the station of a gentleman; that he will pay his tailor, his butcher, his shoemaker, his baker, his druggist; that he will conduct himself in an honest, straightforward manner, paying everybody his due; and having laid down this law for him, Society, when through its parsimony, inhumanity, or neglect, an outcast perishes in its streets, empannels a coroner's jury of this very tailor, butcher, shoemaker, baker, to victimize this doctor, who is so inhuman as to inquire who is to pay him; this hard-hearted practitioner who, expecting to pay, has the audacity to expect to be paid!

But we are told by the coroner, who by the way was paid for *his* services, that humanity is a great thing—a sacred duty—paramount to considerations of profit and loss. Very good—very fine. But let us extend this principle. Are coroners, judges, lawyers, and coroners' juries, to have the benefit of it?

Humanity, we presume, is not limited to physicing paupers for nothing; humanity is not a merely medical virtue, though Society seems to think so.

The prompt administration of justice is humanity, yet what judge on the bench administers justice for nothing? It is humanity to investigate the causes of sudden or suspicious deaths, yet did any man ever hear of any coroner who sat upon any jury since the time of Alfred, without being paid his fees and his mileage? To feed the hungry, to clothe the naked, to visit widows and orphans in their afflictions, is humanity, yet we hear of no tailor, butcher, baker, who refuses to give bread, beef, and clothes for nothing, being told by coroners' juries that "if he gets no money, he gains the esteem of his fellow work-men."

Will the esteem of his fellow work-men feed the poor doctor, or clothe his wife and

children, or pay house-rent, or taxes, or appear on his frugal board in the shape of a leg of mutton and trimmings? Will the esteem of his fellow work-men preserve him from rusty clothes or an empty stomach, from a distress for rent, or from the Insolvent Court?

Let him go to the workhouse with the esteem of his fellow work-men in his pocket, and he will be set to break stones, or pick oakum, just the same as if his fellow work-men did not esteem him in the least; and when he dies, after a life spent in gaining the esteem of his fellow work-men, by running after sick paupers for nothing, let his widow go before a police magistrate for relief, and she will be lucky, indeed, if the esteem of her late husband's fellow-men enables her to take change out of a sovereign.

Medical men are fair game—their profession is a noble, humane, and liberal profession; therefore, be sure, they are expected to be noble, humane, and liberal enough never to expect payment; they are advertised for in the same way as tallow-candles and scrags of mutton, and for the same use—the use of the parish poor; therefore, be sure, they must be gentlemen, disdaining payment!

They have been, and still are, a profession foolishly charitable, and criminally benevolent, to the injury of themselves, their families, and their fellows; therefore, Society takes them at their word; if they work for nothing, they get no thanks, and if they don't work for nothing, they are rebuked by juries of butchers, bakers, and tailors, who glory in the chance of sitting, once in their lives, in judgment upon a gentleman.—*Young England.*

LECTURES
ON THE
NATURE AND TREATMENT OF
DEFORMITIES,

*Delivered at the Bloomsbury Square
Institution.*

BY R. W. TAMPLIN, F.R.C.S.E.
Surgeon to the Institution.

Treatment of contraction of the knee-joint in the flexed position—mechanical and surgical. Means of forming a diagnosis. Case of contraction from inflammation successfully treated mechanically. Signs which may be considered favourable; signs which are unfavourable. Section of semi-membranosus, semi-tendinosus, and biceps; mode of performing the operation. Contraction of gastrocnemius as a consequence; contraction of the flexors and adductors of the hip as a consequence—treatment of. Dislocation backwards of the tibia on the femur—treatment of.

WE now proceed to the treatment of contraction of the knee-joint; it consists of mechanical, or mechanical and surgical combined. It is of the greatest possible importance that you should satisfy yourselves, as far as the case admits of, of the actual condition of the joint, which you will be enabled to do by a reference to the original cause, the duration of the deformity, and the amount of motion, if any, in the articulation. Now the first thing to be ascertained is, whether the disease in the joint has subsided, supposing the contraction to have arisen from that cause, as I need not tell you, that if disease should still be present, it would be imprudent to adopt any active measures to remove the contraction. This you will easily discover by examination of the joint, and by the feelings of the patient. We have at this moment a female about 16

years of age in the Charity, who was sent up a distance of 80 miles from the country; and, upon examination, I found an increased quantity of synovia in the joint, indicated by the prominence on each side of the ligamentum patellæ, as well as by the sense of fluctuation evident on pressure being made. Pain from motion of a shooting character, especially when subjected to a sudden jar; pain also at night, increased, in all probability, by the movements taking place during sleep. The knee contracted to a right angle, and rigidly so; and any attempt to extend the leg increased the rigidity of the flexors, and also gave pain in the knee itself. This affection was occasioned by simple inflammation of the joint eighteen months previous to her admission, but which had subsided, at least the active symptoms, twelve months since. I did not think it advisable, under the circumstances, to have recourse to the operation, but recommended she should be sent to a general hospital until the disease was entirely gone. The Committee interested themselves, but without success, the girl being refused admission on the ground that rest alone was necessary. As, therefore, there was only one alternative, that of sending her back into the country, I thought it would be advisable to endeavour, by careful extension, to straighten the limb by mechanical means alone, so that, in the event of a recurrence of the inflammation, she would at all events be in no worse condition than she then was, whereas, if I succeeded, it would be of immense advantage to the patient. I therefore applied the iron splint, with the male and female screw attached, and to my surprise, the leg has been restored to its straight position; so that here is an instance, proving to you the possibility of drawing out the contracted muscles, and thus overcoming their tendency to contract, without the operation, provided the contraction has not existed sufficiently long for it to

become permanent, and before the disease has actually subsided.

After, then, you have satisfied yourselves of the cause, you will proceed to ascertain, 1st, if there is motion; 2dly, what is the amount of motion; 3dly, what is the *nature* of the motion, and the cause of resistance,—whether that resistance is owing to the muscles alone, or to the muscles and joint itself combined; also, what voluntary power, if any, the patient possesses at the time present. After these preliminary inquiries, let an assistant hold the thigh firmly, whilst you attempt to extend the leg forcibly. If you are able to extend it in the slightest degree, if the patient complains of pain on the anterior surface of the joint, however slight the motion obtained in this way may be, your prognosis will be favourable; and even in those cases where there is no perceptible motion, as in the cases I have described to you of injuries to the joint, in my last lecture, if the patient complains of pain in the situation mentioned, you may anticipate the possibility of removing the contraction. It is also as well to examine the patella, and to ascertain whether it admits of motion in a lateral direction, which you can do in the following manner. Place the thumb or finger of the left hand on the edge of the patella, and with the thumb of the right hand forcibly press on the other side. If there is motion, you will of course feel the edge which is pressed upon depressed, and the opposite edge raised. This is very easily accomplished in some cases, but in others the patella will appear immovable, and require the greatest caution and care before you can be satisfied whether motion exists, as the sensation conveyed by the skin alone, in moving when pressed upon, is likely to deceive you. Here also you will be guided in these difficult cases by the circumstance of the patient complaining of pain, not on the points pressed upon, but beneath the patella, in the joint. Should they do so, you may rely upon it that the patella is not ankylosed either to the femur or the tibia. The patella, in severe cases of contraction, becomes lodged between the condyles, and is firmly held by the rectus above and the ligament below, so that it is often not an easy matter to find or to satisfy yourselves of its position, much less to determine its immovability. I have myself repeatedly been compelled to examine with the greatest care before I could discover it at all. Having satisfied yourselves there is motion, you will then look to its character. If it is a steady motion, and upon an increase of extension the flexor tendons are rendered more tense, you will regard the resistance as confined to the muscles principally; if, on the other

hand, you find upon keeping up the extension for some seconds, that the joint returns to its contracted position with an elastic impulse, you may anticipate resistance, arising from adhesions in the joint itself, and of course you will be more guarded in your prognosis. If you find free motion beyond the contracted or flexed position, that is, if you are enabled to increase the amount of flexion without difficulty, with as much ease as can be done ordinarily, this will be a favourable circumstance. And of course you will, in forming an opinion, look at these indications collectively, having a due regard to the original cause.

If, on the contrary, the joint is immovable, and occasions no pain upon examination; if, in continuing your extension, the muscles relax themselves, and there is no motion or pain, you will regard these as unfavourable indications, and it is hopeless to attempt restoration by the ordinary methods. If you have free motion to a certain point, and the motion becomes suddenly checked, as if by a solid substance, giving you the sensation of its being stopped by a spicula of bone, this also must be regarded as unfavourable. I have seen three cases of this kind, where I believe the patella had become ankylosed to the femur, and from the tibia being drawn backwards somewhat behind the condyles of the femur, the moment the leg was extended to a certain point, it received a dead check stop, evidently caused by the patella being firmly fixed, and pressing on the anterior surface of the head of the tibia, whenever the latter was brought to the point at which the patella was immovable; the joint being freely moveable up to that point in each case.

These are, then, the principal indications for or against the ordinary treatment being followed; I say ordinary, for you must be aware of the femur having been sawn through in cases of complete ankylosis, and immediately afterwards the leg being placed in the most favourable position, so that the bone should become united in the position adopted. This experiment is said to have been successful; but it is quite another affair, and a mode of practice I have not thought it advisable to follow.

Having, then, satisfied yourselves of the probability of being enabled to remove the deformity, you will decide as to the means to be adopted, whether mechanical alone, or surgical and mechanical combined. In all cases where the deformity has been of short duration, and where there is tolerably free motion, I would advise your selecting the mechanical alone, whether the contraction is to a greater or less extent. Bandaging the leg carefully, from the foot above the knee, and adjusting the leg in the position in which it is, in the ordinary knee-splint, with

the male and female screw beneath the joint, and to which I have added a metal plate, to hold the thigh firmly in position, taking care that there is no undue pressure, by straightening the splint more rapidly than the leg can follow, and thus inducing pressure on points, these points being generally just above the heel posteriorly, and the anterior surface of the thigh, just above the condyles, as well as at the extremity of the splint behind the thigh. If, however, the deformity has existed for any length of time, whether it is severe or not, I would advise section of the tendons of the contracted muscles, as well as any dense bands of fascia you may meet with; for in old cases the fascia becomes contracted, and at a greater distance from the popliteal space; and oftentimes you will find, upon examination, the region of the popliteal space filled with one dense mass of contracted fascia, and what I imagine to be thickened and condensed cellular tissue: when it presents this appearance, I need not tell you it would be dangerous to divide the fascia beyond the superficial bands. The patient, then, will be laid horizontally on his face, and an assistant will grasp and extend the leg; you then feel for the tendons, and, as a rule, the biceps flexor femoris will be found more tense than the semi-membranosus and tendinosus. There are, however, exceptions to this rule. Should this be so, you will pass a small sharp-pointed knife on the inner side of the tendon, and beneath it horizontally, or as nearly so as you can, and as soon as it extends to the breadth of the tendon, turn the sharp edge of the knife towards it, and divide it from within outwards (that is, from the popliteal space). After having divided the biceps, you will proceed to feel for the tendons of the semi-membranosus and tendinosus, and should they be prominent, pass the knife, on the inner side of the tendons, beneath them; depress the handle, and divide them from within outwards, as in the other instance. You will then examine carefully for any additional source of contraction, as the bands of fascia mentioned; and if you find them tense, and you can get at them with ease, divide them, but run no risk; for you must recollect that there is the vein, nerve, and artery, and the possibility of an irregular distribution, and the possibility also of a change in the relative position of the vessels, or of their being included in this mass I speak of; and although very frequently you will find it an easy matter to divide the tendons of the contracted muscles, and one or more of the clearly-defined bands of fascia, yet in some cases you will experience the greatest difficulty (strange as it may appear) in satisfying yourself that you have even divided the tendons, however clearly defined

they may have been, and however positive you may feel that you have passed the knife beneath them. This arises from the contraction of tissue which will be felt remaining, and in the position of the tendons; and you may insert your knife again and again, and still feel the chord or chords left, giving you the sensation that the tendon, or a portion of it, still remains. The same remarks apply to the fascia. I would advise you, therefore, to be cautious, and in such cases to rest satisfied with the division of the principal portions, for if you have succeeded in dividing the tendons, you will generally be enabled to bring the leg straight. This applies to simple contraction, without any alteration in the relative position of the bones. If you have also the inward inclination I have spoken of, which can be told by the prominence of the internal condyle of the femur; and if the tibia is rotated slightly on the femur, which I also mentioned to you, you will generally find it necessary to divide the vastus externus and fascia lata, in the manner described in a former lecture. After having completed the operation, pledgets of lint should be placed over the parts of puncture, sufficiently large to prevent any venous bleeding; for you will recollect that the popliteal space is filled with loose cellular tissue, and easily admits of effusion of blood (provided a moderate degree of pressure is not carefully maintained). Retain the lint with long strips of adhesive plaster and bandage, and support the leg with a tin splint, bent at the angle at which the leg is contracted. Allow the lint to remain for a week, provided there is no pain, at the end of which time you will find the punctures healed, and all risk of their reopening effectually prevented. By too early extension, remember, you may irritate the parts of puncture, and be delayed in treatment. We have had one or two cases where a little venous hæmorrhage took place internally; and from proceeding too soon with the extension, inflammation set up around the points of puncture, and the clot, although small, ulcerated out, occupying about six weeks in healing, during which time nothing could be done; and a patient is now upstairs in whom I divided the biceps flexor femoris and vastus externus, for knock-knee, which some of you witnessed, where also this occurrence followed, although in a less degree, but occasioned, in like manner, from too early extension; therefore nothing is to be gained by commencing extension too quickly. I think, however, a week sufficient. In my own practice I always wait that time, and do not consider it prudent to commence sooner, from the quantity of loose cellular tissue occupying the popliteal space. You then apply the means of extension; and in a simple contraction, the ordi-

nary splint, with the plate mentioned to hold the thigh down, you will find the most easy method, both for the patient and yourselves, taking care not to proceed more rapidly with the extension of the splint than of the knee, and being guided in your progress by the feelings of the patient. The extension of any joint that has been long in one position is always attended with pain; and in the knee they will invariably point to the anterior surface of the joint; so that you must proceed according to the feelings of the patient and the resistance met with, which will of course depend on the original cause of the deformity, and the consequent condition of the joint.

In paralytic and congenital cases.—In cases arising from injury to the spinal chord and column, you will not, as a rule, find

much impediment in the joint itself. In cases arising from injuries to the joint, in rheumatic contractions, and in some cases where there has been inflammation of a long and continued character, you will find a greater or less resistance in the joint itself, and of course a more slow and tedious process of extension, and greater care will be requisite throughout the entire treatment. If, then, you have, in addition to the contraction, a lateral displacement, you will find this splint which I had made, and which I have used with great advantage, the best and most simple means to adopt (vide Fig. 1); it has a double action with the male and female screw behind, as in the former instance, and also at the side, so that at the same time that you are extending the leg, you are removing the lateral displacement.

FIG. 1.

The above diagram represents the splint alluded to, which, by its possessing a double action, admits of being applied to any amount of contraction combined with outward inclination of the joint.

In either case you proceed gradually and with care, until the leg is brought into a perfectly straight position, for if you do not, or cannot accomplish this, rely upon it a relapse will follow from slight neglect. After the leg is brought into the straight position, you will do well to keep it so for some time, until all tendency to relapse is overcome, *i. e.* until you find it remain in that position when out of the instrument. You then order an upright support, from the hip downwards, which will hold the knee straight and enable the patient to take exercise, and direct him to exercise the motions of the joint as much as possible, so that the cure may be rendered perfect. The best means of restoring the motion of the joint, is by placing the leg in the instrument, and to flex and extend it by means of the screw; it is a more steady and certain proceeding, and one which is by far the least painful to the patient.

In these confirmed cases of contraction at right angle, or beyond it, the gastrocnemius, from its long flexed position, does not possess the power or means of being properly extended, certainly not with exercise. It therefore will be found to have contracted up to the point at which it has ceased to be elongated, but this will not attract your attention, nor have you the means of ascertaining whether it be so, until you have made considerable progress with the extension of the knee, when the heel will be found contracted at or beyond a right angle; the patient possessing all the voluntary power, but being unable from the contraction to flex the foot beyond a right angle, or even to that point. Several cases of this kind have occurred at this Charity. I have been compelled after the knee has been straightened to divide the tendo-achilles, and in this way the cure became perfected. It is a simple affair, inasmuch as there is no resistance in the joint, nor any great amount of shortening or contraction, and as soon as the tendon is divided, with ordinary care you may flex the foot to its full extent in fourteen or twenty-one days, when the patient possesses the free use of the ankle-joint. Occasionally you will have also contraction of the flexors of the hip-joint, especially if the thigh has been constantly held by the patient flexed upon the pelvis. This is a much more serious and difficult complication, for after you have straightened the knee the patient does not possess the power of standing erect; because if the back is straight and in the perpendicular position, the thigh being flexed more or less acutely, the leg is thrown forwards, and if the leg is in the perpendicular position, the pelvis is thrown backwards; this proceeds from the yielding of the lumbar vertebrae; they being drawn by the psoæ muscles, so that great difficulty and

inconvenience is experienced when the patient attempts to walk, together with great lameness, giving the appearance of a person afflicted with disease of the hip-joint. In this instance, the principal muscles contracted are the psoæ, and it is a difficult and dangerous proceeding to divide them, although I believe it has been done by Stromeyer. I would advise the following proceeding:—let the patient lie flat on his back, with his legs off the edge of the bed; a pillow being placed beneath the lower part of the back, so as to raise the pelvis above the level of the rest of the body, of course as the thigh is contracted, the leg will be considerably above the level of the body; then attach a weight with a band just above the ankle joint, and direct this to be done as long as the feeling of the patient will admit, two or three times daily, increasing the weight by slow degrees; in this way a stretching is kept up in the psoæ muscles, which will by perseverance relieve, although it will not remove the contraction, and enable the patient to get about much better than he could otherwise have done.

Forcefully extending the thigh several times a day with the hand is also beneficial, by getting an assistant or domestic to hold the pelvis as firmly as possible, whilst another with considerable force presses the leg downwards; should you find the rectus, sartorius, tensor vaginæ femoris contracted as well as the psoæ, divide as many of them as can be done with safety. The method of doing which I shall point to you when I come to speak of contraction of the hip-joint. Occasionally, also, you will find the thigh not only flexed but adducted, so that when the leg is brought into the straight position, it is thrown over its fellow. One case is now in the wards, where this condition exists in both thighs, both knees being contracted, with the general spasmodic condition of all the voluntary muscles. If it exists in both limbs, you must as soon as the knees are restored to their straight position commence extension, either with or without section of a portion of the adductors. This may be done in two ways, either by fastening a bandage at the side of the bed, and passing it round the thigh on each side, or else by means of this instrument, (vide Fig. 2), which I have had made for the express purpose. The first method is the most simple and efficient; though only one thigh should be affected, you must still fasten a bandage round each of them, to enable you to act on that which is contracted. In this way you will be enabled to remove the contraction sufficiently to enable the patient to use the limb with comparative freedom; you must, however, keep up this extension night and day, as in other instances, and when the thighs are sufficiently apart to enable the

FIG. 2.

The splint represented in the above diagram consists of two horizontal portions, having in the centre of each a moveable pad, made concave internally, to correspond with the convexity of the inner side of the knee-joint. These pads are united by means of a male and female screw, which allows of their being brought closely together. Straps are attached to encircle the knee, so that it may be fixed in the position desired. By gradually elongating the screw, the legs are insensibly separated to any extent.

patient to sit astride in a chair, let them adopt this method several times a day, sitting with their faces to the back of the chair, upon which they can rest their arms. I must not forget to call your attention to another complication occasionally met with, and which I partially alluded to, namely, displacement of the tibia backwards, (vide Figs. 2 and 4 of last lecture); this sometimes takes place to a great extent, and you have no means that I am acquainted with of remedying it during the time you are extending the leg; you may perhaps do so in part, but not altogether. When this deformity exists after you have straightened the limb, you will find the condyles of the femur projecting to such an extent, as to press almost entirely on the anterior edge of the articular surface of the tibia; in fact, it looks just as you may imagine a dislocation of the tibia backwards would look. And in one case, of which this is the cast, a girl of 19 years of age, (vide Fig. 2 of last lecture), who was an in-patient of the Charity, when the leg was straightened this was the actual condition, and as far as I could discover, the articular surfaces did not touch at all, the head of the tibia appearing to have receded behind the condyles of the femur into the popliteal space; the condyles themselves projecting abruptly, and giving the knee a most curious and unnatural appearance, and rendering it per-

fectedly impossible for the girl to have borne the weight of the body on the leg without forcing the tibia still higher up. It was, in fact, a complete dislocation of the tibia backwards. There must have been an immense elongation of the crucial ligaments, similar to that represented in the diagram (Fig. 4) of last lecture; and were it not for the successful termination of the case, I should have thought they had been completely obliterated. It is the only case I have witnessed to such an extent, although it is by no means uncommon to find this disarrangement partially existing; in whatever degree it must be remedied, as the exercise of the limb in this position must, mechanically, increase the deformity and occasion a return to the malposition, independently of the perfect impossibility of the natural motions of the joint being restored. The means I have adopted, and which perfectly succeeded in the severe case alluded to, and with comparative ease to the patient, consisted of a bandage passed beneath the pelvis on the inner side of the thigh of the contracted leg, well padded and fastened to the head of the bed, the patient lying in the horizontal position on her back. The foot and leg were then carefully bandaged, and the instep padded. A strap was then passed in the figure of 8 form, from above the ankle and over the instep, which strap was attached to a bandage fastened at the

bottom of the bed, a board being fixed there perpendicularly, so that the leg might be slightly raised above the level of the bed. By these means extension was gradually kept up, and as soon as I imagined the head of the tibia was brought down parallel with the extremity of the condyle of the femur, I applied a straight splint behind the leg, extending some distance above and below the knee, padded at each extremity, and fixed by means of straps. A broad webbing strap was then applied just above the condyles, passing round the splint, and was gradually tightened; which, by its action, tended to draw the condyles of the femur backwards, whilst the counter-pressure of the pad and splint below the knee, behind the upper portion of the tibia, had a direct effect to force the tibia forwards. This it effectually did, and without putting the patient to any amount of pain. This, therefore, is the plan I adopt, and which I should advise being followed in all cases of this description. It possesses one great advantage, simplicity in its application, certainly in its result, and it does not unnecessarily confine the patient, or occasion any undue pressure, with ordinary care. If they move out of the straight line, so much the better, as it increases the amount of extension, and assists the cure. We have had, in one case of a female who possessed that unhealthy, fat, flabby condition occasionally met with, phlegmonous erysipelas set up, resulting in sloughing of the cellular tissue at the back of the thigh. The patient had complained of little pain; but on one occasion when I visited her, I found the pad damp behind the knee, when, removing the instrument and bandage, the skin presented that reddish-brown indurated appearance which is so characteristic of this disease, together with bullæ here and there disseminated. I immediately made a large opening at the back of the leg, and let out a large quantity of sanious matter and sloughed cellular tissue. Poulitices were applied, and the limb supported throughout, together with the administration of opium, stimulants, and nourishment of every kind; and the girl perfectly recovered from the effects. The leg was afterwards straightened, and she left the Charity with a useful limb.

I have thought it necessary to go thus into detail, as I know of no cases of contraction that are likely to give you more trouble, or occasion more anxiety, as you will scarcely ever meet with two alike; and without the greatest care all your efforts will be frustrated. The causes vary so much, not only *per se*, but in their effects, that in proportion to the change that has taken place in the joint itself, or in the synovial membrane covering it, will be the difficulty attending the treatment. These changes,

unfortunately, cannot be accurately ascertained. You may, with the directions I have given you, form an opinion; but this, as in every disease met with, must occasionally be erroneous; for occasionally we cannot foretell what, or if any, adhesion exist in some cases; neither can you tell the precise condition of the synovial membrane and ligaments. In fact, there are no cases in the range of deformity so difficult, tedious, and embarrassing as these.

It is a curious circumstance, and one that I am unable to explain, that the pain these patients complain of is always on the point of the knee, in one spot, and not diffused over or through the whole joint, as we should *a priori* have anticipated, whether the knee is contracted in the straight or flexed position. The time occupied in treating these deformities will vary, according to the age of the patient, the cause producing it, and the length of time the affection has existed. In cases arising from punctured wounds, I have succeeded, contrary to what I should have anticipated, in restoring the position in six or eight weeks. In cases arising from scrofulous disease about the joint, in three or four months (I am speaking of adult cases). In younger subjects, after the operation, it can be done in six or eight weeks. In cases occurring from rheumatism, from three to six months or nine, as this of all the causes appears to destroy the integrity of the joint the most rapidly, and to become irremediable in a comparatively short time; so that no delay should take place in the treatment, provided treatment is decided upon. In these, as in all deformities, never omit artificial support, until the balance of power is restored between the flexors and extensors, as, if you do, whichever may preponderate in power will, from my experience, certainly become contracted, and occasion a permanent condition of one of the motions of the joint.

OBSERVATIONS

ON THE

NATURE AND TREATMENT OF THE MORE IMPORTANT DISEASES OF THE NERVOUS SYSTEM :

With Illustrative Cases.

By EDWARD BLACKMORE, M.D. Edinb.

Member Extraordinary of the Royal Medical Society of Edinburgh, and Physician to the Bath Penitentiary.

Medico minimum est de Arte loqui :—
Multo maximum est ex Arte facere.

(For the London Medical Gazette.)

THE cases in the present essay are selected with a view to illustrate the

pathology and treatment of apoplexy, palsy, water in the head, epilepsy, tetanus, chorea, convulsion, hysteria, and insanity.

The observations are founded on a collation of cases which have come under the notice of the writer, and the majority of which have occurred in his own practice in the course of the last twenty-five years. The deductions are concise, and meant simply to direct attention to the narratives of the cases, from which it is believed that the student of his profession may best derive for himself the more useful suggestions. They who are engaged in the bustle of practice will excuse the interrupted and aphoristic form of the observations, and will regard them as mere hints for reflection. The young practitioner may, it is hoped, find in them some aids to relieve him from the embarrassment of the sick-room; and the more experienced may be reminded by those narratives of many interesting incidents in his own experience, although he may not learn from them any novel facts.

CLASS I. THE COMATOSE AFFECTIONS.

Section I. On Apoplexy.

A most important and interesting feature of apoplexy—whether idiopathic or secondary, of the simple form or attended with convulsions or palsy—is, that its invasion is seldom absolutely sudden and without premonitory signs—signs sufficient to rouse the attention of the patient, or of a vigilant observer, and to lead to precautions by which, in many cases, the complete attack, or its fatal consequences, might be prevented.

These premonitory symptoms are, indeed, very diversified: sometimes they are long antecedent to the fit; sometimes pre-existing only for a few days or hours; sometimes they are continued, more often remittent.

They may be viewed as referring principally either to the functions of the brain, or to those of the digestive organs.

1. The symptoms chiefly referrible to the nervous and sanguiferous systems present themselves under two forms:—

a. That marked by plethora in the system, or by increased vascular action about the head—the common form of sanguineous apoplexy. The particular

symptoms are shivering; headache, dull and oppressive, or acute, constant or remittent, in some cases singularly subsiding shortly before the apoplectic invasion; delirium; slight convulsion; feelings of heat and turgescence in the head; a throbbing at the temples; swelling of the face, which is pallid and cold, or flushed and heated; vertigo in the common form of seeing objects in motion, or the more alarming kind, feeling himself in motion; momentary loss of vision; sleeping, or lethargy not amounting to stupor, attended with a sense of lassitude, apparently from debility, but which is really from incipient pressure on the brain; while the pulse is becoming full, firm, and slower than ordinary.

b. The second form is a state remarkably different from the former, characterized by a leuco-phlegmatic habit; pallidness and coldness of the face; lowness of spirits, sometimes amounting to mental despondency; nervous irritability; and, in some cases, deceptive hysterical symptoms; slight transient paralytic feelings; giddiness; intolerance of strong liquors; a weak irregular pulse; transitory sickness and faintness. In some cases, in exhausted constitutions, an increase of debility shortly before the apoplectic attack; in others a wonderful transition from a state of great and protracted weakness to one of vehement action of the whole vascular system, and particularly of the arteries about the head, which has required the loss of thirty ounces of blood from the temporal arteries before it could be controlled.

2. Another class of symptoms refers to the state of the stomach and bowels. In some cases they are those of a long and habitual dyspeptic affection, without head symptoms adequate to excite a suspicion of the serious disease which is forming in the brain. Dyspeptic symptoms during pregnancy, and appearing to proceed from uterogestation, are sometimes occasioned by latent disease in the head, which is to end in apoplexy. Sudden vomiting is, in some instances, the earliest symptom premonitory of the most dangerous form of apoplexy: in one case there was vomiting of all the ingesta for six weeks before the fatal coma! Costiveness is a frequent precursor of sanguineous apoplexy; and the interruption of the action of the intestines for a

single day has had an injurious effect on the brain.

The phenomena of the fit are as diversified as those of the antecedent state, *e. g.*—

a. Sudden profound coma, with depression of the vital powers, or syncope, rapidly fatal, without re-action.

b. Coma, more gradual, attended with a momentary depression of the vital powers, to be followed by strong reaction or inflammatory symptoms.

c. Coma, with a full, swollen, heated state of the head, and throbbing of the temporal arteries; and

d. Coma, with a tumid, pallid, cold face, and cold extremities, but with a distinct pulse—a state which might easily be mistaken for one of collapse of the vital powers from a sedative influence, and in which an error in diagnosis would lead to serious consequences. A most impressive example of this variety occurred to me in a robust child, three years of age, who was one morning suddenly affected with extreme languor, paleness, coldness, and loss of sense—a state exhibiting a combination of lethargy and syncope: it was the third attack of a similar nature in six months. There was evidence of a torpid liver shortly before the attack, which fortunately suggested the appropriate treatment.

Apoplexy is frequently a secondary affection, supervening on various diseases, particularly

On gout, and that with fewer premonitory symptoms than usual;

On inflammation in the lungs, of which Case I. is an example;

On diseases of the heart and aorta, which is often unsuspected;

On disorder in the liver, particularly when attended with icterus, or with ascites;

On chronic dropsical affections, in which the febrile excitement has seemed to have conduced to the cerebral congestion;

On protracted inflammation in the stomach or intestines, in a scrofulous constitution;

On disease in the kidneys, especially when attended either with albuminous urine, or with a suppression of urine;

On disease in the spinal cord, whether acute or chronic, of which Case VIII. is an interesting example;

On chronic epilepsy, as in Case IX.;

On a very deceptive remittent and

protracted form of inflammation in the brain, of which Cases I. IV. VII. are examples;

On organic disease in the encephalon, as in Case X., the symptoms of which—prolonged vomiting and costiveness—indicated rather a disease in the intestines of the nature of ileus.

The slightest symptoms of disorder in the head supervening on other diseases, particularly in a cachectic constitution, require the most vigilant attention, for it unfortunately often happens that their importance is not always duly estimated. The symptoms of the primary disease sometimes remit or disappear, while the morbid irritability and plethoric or inflammatory diathesis of the constitution remains, to become a prolific source of no distant danger. In some cases every other symptom of this antecedent morbid state disappears, but the pulse continues high and firm, and full of warning to the practitioner. Sometimes, however, even the pulse is deceptive, and falsely betokens convalescence.

It is true, indeed, that a slow full pulse, after the cure of an inflammatory disease, may be a sign merely of the exhausted excitability of the vascular system. I have known it, in such a condition, fall from 80 to 40, and excite great alarm, yet by a judicious cordial treatment it has become natural, and been followed by perfect recovery; more generally, however, a slow pulse, after an inflammatory or congestive disorder, should be viewed as a sign of danger threatening the brain.

If a severe disease in the thoracic or abdominal viscera, or a disease from a powerful exciting cause, as severe exposure to cold, or too high living, has not been treated by adequate remedies, a serious secondary brain affection may often be expected; and this particularly, if the tongue remains white and loaded, although the other symptoms may have improved. The slightest headache is in this state important: if it is neglected, one premonitory symptom will succeed to another; fulness of the face, noises in the ears, vomiting, and a slow unequal pulse, until shortly the paroxysm sets in in its full force.

It cannot be too strongly impressed on the mind of the practitioner, that the premonitory symptoms of both primary and secondary apoplexy are often in-

adequate signs of the severe attack that is forming itself. In order to estimate aright their real import, the character of the constitution should be well considered, and not merely their actual violence. In irritable, scrofulous, gouty, or cachectic constitutions, symptoms apparently insignificant turn out to be highly important. I have seen in a patient with a constitution broken by syphilis and mercury, a slight headache, attended with giddiness and a slow pulse, unexpectedly terminate in fatal coma. Death has also occurred, in such a subject, unexpectedly, without coma, when the symptoms appeared to be merely a threatening of an apoplectic attack, the only alarming symptom being the pulse falling to 46!

In strumous subjects, also, where merely slight symptoms of encephalic disorder—as headache, vertigo, confusion of thought, and debility of mind—have existed for some time, with impaired power of voluntary motion of any part, apoplexy is liable to be induced on the slightest occasion. The vascular system in such subjects is so irritable or so weak, that when the vessels of the brain are distended and dilated by a load of blood, their contractile power is destroyed, and, in consequence, a congestion, at first slight, increases progressively, until the apoplectic condition is fully formed. In such subjects, also, a previous softening of the brain favours a diffused effusion of blood that is inevitably fatal.

It is consolatory, however, to know, that, in many cases, severe symptoms have passed harmlessly away on a recourse to remedies, or even without medicine, by the action of the healing powers of the constitution, manifested particularly in an eruption of boils, or of erysipelas, or gout.

The *prognosis* is bad when apoplexy is the sequel of severe antecedent disease. Tonic spasm, involuntary stools and urine, a renewal of convulsions, dilated pupils after a contracted state of them, a different state of the two pupils, as one being fixed and dilated while the other is contracted, a quick irregular pulsation or slow pulse, mucous rattles in the throat, and a failure of animal heat, are fatal symptoms. In some cases a *deceptive amendment* is seen just before the fatal termination! Black blood seen in bleeding, particu-

larly from the temporal artery, is a bad sign. Reaction following a depression of the vital functions is not of itself a ground of hope. Coma of twelve hours duration may end in recovery; its importance is to be judged of more from the state of the vital functions and of those of the spinal cord, than from its mere continuance: and even exhaustion of those functions is not always hopeless, if it arise from incidental circumstances rather than from pressure on the medulla oblongata; the recognition of the former cause is founded on the regularity of the pulse and of the breathing, and on the coma being less profound. Coma succeeded by a phrenitic state is hopeless; and also when following bronchitis: in some cases, however, profound apoplexy, when it has been preceded by decisive symptoms of chronic inflammation in the brain, is not fatal, as seen in Case XIV.; but there is great danger of its recurrence, at an uncertain interval. Apoplexy succeeding to icterus, and to suppression of urine, and to the retrocession of gout or of erysipelas, is generally fatal. Coma after concussion of the brain, even of many days continuance, but not profound, is not hopeless. See Case XVI.

The most common morbid appearances in apoplexy are excessive enlargement and sanguineous engorgement of the blood-vessels in the brain. This state is seen to exist, either by itself, or in complication with other morbid conditions: *e. g.* (a) effusion of serum; (b) effusion of blood, circumscribed or diffused, co-existing with simple dilatation of the vessels, or with disease of their coats; (c) extensive softening or ulceration of the medullary substance (Cases II. III.); (d) encysted suppuration (Case IV.); (e) tubercular disease (Case X.).

In cases where no morbid appearances are found, which were formerly styled nervous apoplexy, and more lately simple apoplexy,—it is not to be inferred that this is a true type of the vascular condition of the brain at the time of the invasion of the fit. In the first case hereafter narrated, it is obvious that the active treatment shortly before death must have tended to efface the natural characters of the disease during life: and death itself so much favours the contraction of the previously dis-

tended vessels, and even the absorption of effused serum, as to produce the deceptive negation of the usual anatomical characters.

As to the pathology of the disease, it is evident, from the symptoms and the morbid appearances, that the immediate cause, in a large majority of the cases, is a rush of blood to the brain, occasioned by the vehement action of its arteries; and it is probable that this spasmodic action of the vessels continues until, from the failure of the respiratory function, black blood is circulating in the head. And indeed, even this condition of venous blood being in the arteries of the brain, does not instantly put a stop to the excessive vascular action; for while the temporal arteries have been violently throbbing, the blood drawn from them has been seen to be black.

It is no disproof of this view of the proximate cause of the fit, that sometimes, from the moment of its invasion, the pulsation at the temples is low and the face cold; for the capillary branches of the internal carotids are unquestionably sometimes in high action when the branches of the external carotids are in an opposite condition. This view is easily understood from hydraulic principles, and is confirmed by the fact, that on lessening the determination of blood to the brain, the circulation in the exterior of the head is seen, in these cases, to become excited.

It is not manifest that venous congestion is ever the immediate cause of the apoplectic state. Even in the case that most favours this supposition,—in apoplexy connected with disease of the thoracic aorta or of the heart, the accumulated blood in the veins appears to act as an irritant to the capillaries of the brain, which are thus excited to spasmodic action; or the apoplectic congestion may be explained on the supposition, that in the irritable state of the vascular and nervous systems, so often attendant on disease of the heart and arteries, the ordinary mental and physical agents become sources of irritation to the cerebral vessels, which then pump up an inordinate quantity of blood into the brain. This reasoning may also be applied to an apoplectic state supervening on the whooping cough.

The suspension of the functions of

the brain appears to be referrible to the pressure of the accumulated blood; and partly also, to the influence of undecarbonised blood on the medullary substance,—as appears from the fact that the coma does not always go off as soon as the pressure must have been relieved by the depletory remedies.

The phenomena have been referred by some pathologists to interruption of the circulation rather than to the influence of pressure; on the assumption that the quantity of blood in the whole encephalon is invariable, and that from the structure of the skull an accumulation of blood can only take place in one order of the cerebral vessels, the other orders being then in a state of comparative bloodlessness. It is, indeed, demonstrable that the capillaries and the large vessels of the head are not always in correlative states of plethora; and it is equally certain that the brain does suffer in its function from a load of blood in it. I have seen a case of hydrocephalus, in which the coma was relieved on the sutures giving way, and widely separating; a proof that the brain had been suffering from compression.

This view of the pathology of the disease refers to the cases that more commonly come under medical observation. There is also a class of facts that renders it probable that the apoplectic engorgement of the brain is not invariably attended with high action of its vessels; *e. g.* in apoplexy from a sun-stroke in hot climates, and from lightning; in which cases the vessels are turgid, and extremely relaxed and dilated, as if their contractile power had been rapidly and entirely destroyed by the peculiar influence of the exciting cause. I have seen also this state of the head in a man found on the seashore dead from drunkenness. In the fatal lethargy from intense cold, also, a similar state of atony and fulness of the vessels of the brain seems to be induced: and it is probable that the condition of the brain is similar in the slow invasion of coma from narcotic poisons, particularly hemlock, and from foxglove, and from prussic acid, when the dose was insufficient to kill instantly.

The effusion of serum does not seem to be in any case the cause of the invasion of apoplexy; it certainly serves

to maintain the comatose state, although it probably contributes less to it than the vascular congestion does.

The diffused effusion of blood appears to be more closely related to the attendant softening of the brain than as a mere coincident. Extensive softening seems, in Cases II. III., to have persisted for some time, and to have given a predisposition to the sanguineous effusion on the occurrence of active determination of blood to the head. It is obvious that, in such an antecedent state, a very slight increase in the momentum of the circulation would be likely to terminate in effusion. This softening is not always referrible to inflammation in the brain: it appears sometimes to arise from defective nutrition of the organ, as in Case III., where it was connected with poverty and mental depression.

The apoplectic engorgement connected with previous protracted inflammation in the brain, is well exemplified in Cases I. IV. and VII. This inflammatory state is especially insidious; it is not adequately manifested in the state of the pulse, or in the symptomatic fever; and when its outset has been strongly marked, its remissions are fatally deceptive. In a scrofulous constitution it is sometimes very acute, and rapidly fatal; more generally, however, it is languid and chronic. In other cachectic affections, also, it is, as might be expected, of an asthenic character; in a patient in broken health from visceral disease, in whom severe headache, vertigo, confusion of thought, squinting, convulsion, and coma supervened, the sole anatomical characters were turgid and relaxed vessels, and effusion of serum into the ventricles.

In gouty subjects apoplexy is usually connected with intense vascular excitement in the membranes of the brain; and with effusion of blood in the ventricles, without softening of the medullary substance.

It is unnecessary to remark on the importance of prompt treatment wherever strong premonitory symptoms are instant; it may not, however, be needless to urge attention to the remote causes, as well as to the actual symptoms, as a guide to practice; a strong exciting cause will be followed by a strong disease, although the symptoms do not always manifest its real severity.

The importance of regulating the diet, of promoting the excretions, and of avoiding or removing the ordinary causes of excitement, is well recognised; and in the slighter threatening of the disease it may be sufficient to cut the hair, and to enjoin the use of purgatives and the cold affusion. A close examination of cases, however, will show that oftentimes reliance is placed on these means when the treatment should have been more active. Purgatives and low diet are not always safe substitutes for the abstraction of blood. The first of the cases below described shows that the omission of bleeding in the previous stage may not be repaired by the most vigorous use of later remedies; and, on the other hand, early symptoms that have not yielded to free purging have instantly given way to a single cupping or venesection. General bleeding is preferable in most cases to leeching, and even in weak subjects leeches are inferior to the cupping-glasses. It is necessary, indeed, to remember, that when the brain has long been in a state of congestion, a small bleeding may induce fainting, and in one case it was followed by unexpected death. The operation had therefore better be done in the horizontal posture, and the patient precluded from exertion after it.

Of purgatives, those are preferable which produce watery stools, as elaterium and croton-oil, or jalap and gamboge, with senna and neutral salts. The addition of meadow-saffron vinegar to the black draught adds much to the hydragogue effect, and powerfully relieves the head.

The utility of various means of counter-irritation and revulsion, in averting a threatened attack, is abundantly established; one of the best measures is an issue in the scalp, made by an incision, and stimulated to a free discharge by proper dressings.

The cold affusion, especially the shower-bath, has appeared in high-blooded subjects to excite a dangerous reaction; in some cases cold washing instantly after a sub-tepid lotion has answered better.

When head-symptoms occur in the course of other diseases which persist with the secondary affection, the attention is sometimes fixed on the primary disease, to the neglect of the brain affec-

tion, or a delusive hope is entertained, that the latter, being sympathetic, will subside with the former without any specific treatment.

When the head-disorder has been preceded by pulmonary symptoms, extreme caution is required in the use of narcotics. In such a case, in an adult, I have seen fatal apoplexy after a quarter of a grain of muriate of morphia, given to relieve sleeplessness. In this complication of diseases, also, the inhalation of hot vapour for the bronchial irritation has seemed to favour the comatose attack.

The utmost caution is required, also, in the use of tonics, and of iodine, in strumous subjects, in whom the constitutional debility may seem to be the chief object of practice. In one case of slight but protracted headache and cough, supposed to be connected with weakness, very small doses of the tincture of muriate of iron with laudanum, repeated only for three days, occasioned profound apoplexy. In another case, of disease in the liver, with ascites, head-symptoms, that at first appeared of little moment, passed into a fatal affection—mercury with opium, and wine and porter for the exhaustion consequent on diarrhœa, being persisted in, while the appropriate remedies for the brain-symptoms were postponed. Mischief has also followed an attempt to check a diarrhœa co-existing with headache; in this case opium and digitalis seemed alike injurious; indeed, the latter medicines appear to have been often injurious in head affections—a comatose tendency, which has passed into serous apoplexy, has come on while foxglove was given largely for dropsy: this drug appears to weaken the vessels of the head, so that, on a slight excitement of the circulation, a serious passive congestion is consequent.

Serious consequences have also arisen from regarding head symptoms as merely symptomatic of worms; a view which has obtained a general reception from the fact that alarming nervous symptoms have vanished on using an efficacious *vermifuge*.

Harm has also arisen from trusting to mercury alone, when bleeding and purging should have been premised.

Many experienced practitioners will have seen reason to regret the conse-

quences of being content with merely a mitigation of the premonitory symptoms. It is, indeed, natural to feel unwilling to excite alarm by proposing active measures or disagreeable restriction, when the peremptory necessity for them is not obvious to the patient himself. It will, however, conduce to a more complacent retrospect of one's professional life, to have acted in these brain disorders, at least, on the principle that it is safer to treat slight symptoms by active remedies for a few days, than to allow a serious disease to form itself by an erroneous leniency.

Treatment of Apoplexy in the fit.—It is a most important general principle of the treatment, not to trust to any one remedy, however vigorously employed, but to institute a well-combined system of means. Blood-letting is of course the first remedy: it would often be more efficacious if it were more rapid and extensive. In two of the subsequent cases it was carried to the extent of fifty ounces and upwards, at one time, with the best effect. In one case the veins of both arms were opened together. In another case, when, from severe tonic spasm of the arms, it was impossible to open a vein there, thirty ounces were obtained in a continued stream from the temporal artery. The good effect of free bleeding from extensive incisions in the scalp is to be seen in another of the cases; no leeching could have acted so rapidly and beneficially. To bleed from an artery and vein at the same time, will, in some cases, be good practice; and cupping-glasses on the scalp seem always preferable to leeches.

When a large abstraction of blood has failed to relieve the coma, and when tonic spasms have succeeded, it will be better to abstain from further bleeding in any mode; a second bleeding in such circumstances, even to a small quantity, will sometimes induce convulsions, and bring disgrace on the practitioner; and to bleed at all, after the coma has been followed by involuntary stools and tonic spasms, and a failing pulse, will be fruitless, if not pernicious.

The cold-dash, or a continued stream of cool water on the head, is a most powerful remedy, and is particularly useful in apoplectic puerperal convulsions, and in the convulsions of chil-

dren. When bleeding has failed to carry off the coma, the cold affusion has quickly restored sensation.

A current of cool, or, at least, of fresh air, is nearly of equal importance with the cold affusion.

Purgative clysters should never be omitted; and the decoction of senna with salts is better than turpentine, in the comatose state, while the pulse is high. When the power of swallowing is restored, the croton oil is invaluable; and when merely dropped on the tongue, without being swallowed, it may excite purging. Cooling purgatives should be persisted in as long as the tongue remains white and dry: calomel, with gamboge, and the decoction of senna, with soda and Glauber's salts and tartarized antimony, have been found the best combinations. In some cases, aloe and colocynth have been chiefly trusted to, with an unsatisfactory effect.

Mercury is a most valuable auxiliary to bleeding; it prevents or cures that slow inflammation which is too apt to follow apoplexy. It appears from a careful comparison of cases, that even large bleedings, when mercury has been neglected, have been less successful than less profuse bleeding with mercury. The *bichloride* will often be found more powerful than calomel: it has a stronger and quicker influence on the secretions and excretions, and thus quickly relieves the plethoric state.

Have not Emetics, once a favourite practice, gone too much out of use? It is a common idea that they favour a dangerous congestion of blood in the head: this possible effect has, in my experience, been more than compensated by the consequent depression of vascular action; at least, when the vomiting has ensued from colchicum: and when the immediate exciting cause of the coma is in the stomach, common sense and experience agree in pointing out an emetic. An easy disgorge of the stomach may generally be obtained by a strong infusion of ipecacuanha with soda, which is preferable to giving the powder.

In that somewhat perplexing case, of sudden coma attended with a depression of the vital functions, which might seem to suggest the use of diffusible stimulants, it has been found that cold to the head, and warmth to the feet, is the best cordial; and the

hot bath, so commonly deemed a panacea for the convulsions of children, is not safe in the apoplectic state: a stimulant clyster and a sinapism will be the safest means of promoting reaction.

The continuance of coma after the use of active remedies is naturally a source of anxiety to the attendants; experience shows that the best course in such a case is to drop ether on the head, administer a turpentine or assa-fœtida clyster, to apply stimulant embrocations on the back, and sinapisms on the calves of the legs, and, in the patience of hope, to avoid over-officiousness. In some cases the coma has continued for twelve hours, and then the salutary effects of the remedies have shown themselves.

In apoplexy from narcotic poisons, it is of consequence not to omit remedies for the state of the brain, while one's efforts are directed to evacuate the noxious matter: in poisoning from opium and alcohol, bleeding and the cold stream on the head may be as necessary as the stomach-pump.

[To be continued.]

NOTICE

OF

THE MEDICAL ORGANIZATION, STUDIES, &c. IN ITALY.

By EDWIN LEE, Esq.

(For the *London Medical Gazette*.)

[Continued from p. 443.]

Students—Discipline—Examinations.

THE Archbishop of Seleucia says, in his project of reform, "the celebrated Antonio Canova was indignant at the sight of so great a number of young men brought up to the art of sculpture, saying, that the great number of them obliged to exist upon their own resources could afford no service to the art nor to society. With the same feelings, those persons who have an interest in the prosperity of States, and in the splendour of classical studies, regard the useless multitude which dedicates itself to literary cultivation.

"If it be true that society cannot subsist and develop itself except by favouring literature, it is nevertheless clear that a certain restriction of the number of those who cultivate it ought to be established. Society requires only a given number of philosophers,

physicians, lawyers, &c. because it cannot support all those whom an inconsiderate caprice impels into those different directions. Consequently, individuals on leaving the scientific institutions, (with the exception of a limited number) are exposed to the want of bread; they annoy the governments by repeated solicitation of employment and assistance; but they do so in vain, for it is impossible to meet all the exigencies thus occasioned. In this manner, having from their infancy unadvisedly chosen their profession, they find themselves exposed to pass their days in neglect and misery, dissatisfied with themselves and with others. If to these considerations it be added, that many of them are not adapted to acquire a high reputation, and a position with respect to fortune corresponding to their literary education, it may easily be perceived to what dangers society is continually exposed, and what bad services it may expect from these young men, with scanty knowledge and fortune. Let us hope that when, by means of better regulations, and the progress made in the arts and in industry, the inferior orders will have reason to think themselves happy in their proper position, we shall see arrested the torrent of this mass of writers, who, without vocation, and God knows how, sometimes with negative dispositions, besiege at the present day the portals of the University."

These reflections, made with reference to Italy, will likewise be just when applied to France, inasmuch as that which in Italy is expressed as a means of prevention, is already verified in France by the course of events. The principle of political equality, which is serviceable as a barrier against the pretensions of the old aristocracy, by penetrating into the modes of education, has produced a general change in the classes. With a little Latin and Greek in his head, a little mental activity, with the instances before him of rapid fortunes, the fruits of talent or audacity, each one has thought himself predestined to an exceptional position, and has thrown himself upon the public, seeking everywhere a stepping-stone wherewith to raise himself above the multitude. There is now no restraint as formerly, no direction of the Government since 1830, in conse-

quence of the adoption of the sovereignty of the people as an axiom of public right; no intellectual vocation, because the system of instruction renders every man fit for every thing, and is conducted in such a manner that he is not particularly fitted for anything. There is, then, no reason to be surprised that this overwhelming torrent should break through the defences raised by the authorities, and that it should threaten not only the political constitution, but also the social existence in its more important foundations. It was estimated a few years ago, that of 35,000 pupils in the small seminaries of France, 5000 only were destined for the priesthood. Thus (it was said) there are at least 25,000 individuals (even admitting that many of them were in a certain position with respect to fortune) cast every seven years upon the secular part of society, half-instructed, and ready to encumber the schools of law and medicine, which are their only refuge against starvation, because none of them would return to the plough from whence he was taken.

After these statistical calculations, come epigrams, more or less witty, of lawyers without clients, doctors without patients, masters without scholars; which calculations and epigrams might be translated as follows:—either public instruction is badly distributed, or the students arrive in the faculties with too scanty guarantees for the security of society.

The mode in which all the states of Italy are constituted, with an organization nearly homogeneous, still preserves the difference in the condition of their aristocracy and their agricultural population, which separation is general and well-defined. The middle class, mixed up with the industrial and operative classes, does not present a very marked individuality. The apprehension cannot, therefore, be reasonably entertained of seeing places invaded by those upon whom, in France, power and influence have devolved. Industrial celebrities, artisans raised above their original condition, are rarely met with in Italy. There, liberalism, the faithful expression of moral and rational progress, is concentrated among the lawyers and physicians, but there does not exist below these, as in France, (especially since 1830) a numerous class of eloquent *proletaires*, who have an

interest in exciting revolution; consequently, the admission to the Italian Universities need not be guarded by too many difficulties. With respect to knowledge, the presentation of a diploma of bachelor in philosophy; with respect to morals, a certificate of good conduct from the priest; with respect to means, the deposit of a sum required for five years' study: such are generally the preventive guarantees required from every Italian student.

In some countries, however, more is required. In the Faculties of Piedmont, inquiry is made with respect to the position of the student's family, the means which they possess, and the avocation of the father. The *magistrati della riforma* are likewise enjoined not to admit persons of low extraction, or inferior condition, to the acquisition of academical degrees, unless they have exhibited proof of more than ordinary talent. It may be questioned whether the magistrate has been often obliged to exercise this right of exclusion, because the necessary pecuniary sacrifices required for university studies would mostly suffice to retain in industrial avocations those who might otherwise be tempted to leave them. In order to prove this fact, it will suffice to indicate the number of students in each university, as compared with the population of the different states.

Pavia and Padua, the resorts of students of the Austrian territory, not only as far as the Adriatic, but even to the district to which the influence of Vienna extends, have never exceeded—the former 900, the latter 1800 students; of whom 450 of the one, and 600 of the other, were medical. Besides, there has been a considerable diminution in the number of late years. Padua, especially, has seen the *personel* of its faculty diminish in a most discouraging manner.

The number at Bologna had not exceeded 500 (of whom 150 medical). At Vienna it is restricted to 300 (100 medical and 150 law). Pisa has generally had from 600 to 700 students (about 200 medical). In these two last-named universities the communes of Tuscany maintain 100 students gratuitously.

Students in Italy, once admitted to the University, are free to live in whatever part of the town they please, except at Modena and at Naples. In the former, they all live in an establishment which depends upon the govern-

ment, each paying thirty francs a month for his board and lodging.

At Naples, the government founded, about thirty years ago, a kind of pensionate for 100 students, in order to improve the study of medicine, and at the same time as a means of preserving the youth from the corruptions of the capital. For a moderate annual contribution they receive instruction, board and lodging, are subject to a regular discipline, and are under the direction of the junta of public instruction. Their professors, elected by concours, are regarded as substitutes in the faculty of medicine. They wear an uniform, and are admitted only after an examination in Latin and in literature. Five years are allowed them to take a degree in the medical or surgical profession; at the same time they improve themselves in languages, mathematics, and philosophy.

The administration of this establishment is confided to a special commission, and the instruction to eighteen professors, assisted by six inspectors of the studies. At the expiration of each year the pupils undergo a public examination, under the direction of these latter. Any one may interrogate them, and if they answer successfully they pass to the superior grades, and receive the diploma of the faculty: the most distinguished of them, after five years' study, obtain the *Laureat*, without paying any fees to the University, as a recompense for their conduct. It is, in fact, a kind of polytechnic school of medicine, as a great number of individuals from the Medico-Chirurgical College are destined to supply the public services of the kingdom.

Besides this peculiarity, Naples differs from other cities in Italy and France in the circumstance, that, in addition to the University courses, private instruction has acquired a great development, and the lectures of professors surpass in importance those of the official professors. This liberty of teaching consequently produces a facility in collecting students into particular boarding-houses, which are frequently kept by the professors, or by persons selected or authorised by them. Students are, therefore, not left absolutely to themselves, but they are at liberty to change their master and lodgings whenever they please.

Students in Piedmont provide their

own lodgings, but it must be in a lodging-house approved by their superiors. They are obliged to return home on the approach of night, in order to prevent them from frequently resorting to the theatres, balls, or public amusements. They are likewise prohibited from entering *cafés*, or other places where games of chance are played, under the penalty of losing fifteen or twenty days of their lectures.

The assiduity of attendance is proved by certificates given by the professors every two months; who, moreover, devote one day of the week to directly interrogating them—thus the student cannot escape their vigilance. Every month the student must present a certificate of having confessed himself: this regulation likewise holds good during vacation. He is enjoined to receive the communion at least at Easter, and to attend on Sundays and holidays divine service in the oratory of the University, and in the presence of the professors of each faculty.

Medicine appears to be in a very backward state in the Duchy of Modena, where, according to M. Combes, doctrinal tradition is preserved intact. There, no one is allowed to question the Hippocratical test—a sacred ark which none may touch without sacrilege. The following is an account of a public session, at which M. Combes was present:—

On the 5th of July, 1841, in the capital of this Duchy, which is smaller than many departments of France, the termination of the scholastic year, and the conferring upon ten students the degree of Doctor of Medicine, were celebrated. The meeting was presided over by a priest, who arrived in a carriage, and was received with the greatest distinction, his entrance being announced by noisy music. This was the Grand Chancellor, the head of public instruction. The assembly, though not public, was numerous and solemn; but this scenic demonstration bore a character of gravity and strangeness which, if in France, would require one's ideas to be carried back a hundred years from the present time.

The candidates descended to the gate to receive the Grand Chancellor, clothed in characteristic black robes. When the president had taken his place, the professor who had to deliver the ordinary discourse named the ten candi-

dates, who placed themselves behind him, and facing their judges. The trial of each consisted merely in the oral exposition of a text of Hippocrates; the argumentation was restricted to a question, followed by an answer as short as possible. There was no actual discussion, but in its stead salutations, exaggerated compliments, given and received with an admirable *sang froid*, and which imparted to the ceremony a character of mere external formality. After this trial, if such it can be called, the Chancellor asked the assent of the professors, who gave it unanimously. The law was then read, conferring upon the newly elected the right of practising. The *Promoteur* invested them with the professional insignia, after having made them successively swear, kneeling upon the works of Hippocrates.

Then began the discourse of the before-mentioned orator, who this year was the professor of botany. He spoke in Latin, and at great length; his reasoning seemed to have reference rather to a religious question than to scientific facts. All the eighteenth century and its most illustrious names, Voltaire, Maupertuis, were violently attacked, and accused of materialism, as were likewise the greater part of our modern celebrated men, Geoffroy Saint-Hilaire, Dutrochet, Bory de Saint-Vincent, &c. He fulminated against human pride, the source of that pretension to generalise with which France appeared to be agitated, and he finished with an invocation to the Almighty and Omnipresent God. Except the preamble, it all savoured more of a sermon than a philosophical dissertation, and from the pulpit might have appeared opportune and useful, but on such an occasion as the present it was, at all events, out of season.

The ceremony being concluded, the music again sounded, and the ten new doctors reconducted the Grand Chancellor to his carriage.

How can such a fact ever be reconciled with the events of our epoch? Pure Hippocratism, and a sermon for an academical discourse! how can these strange things take place amidst the medical movement of Europe, even if the science be supposed stationary in some places? Such is the problem which we propose to France, where religion is always supposed to be opposed to science, whose doctrines are

attacked, but whose productions are devoured, even in the little Duchy of Modena.

Homœopathy in Italy.

Homœopathy has long ago been judged in France. Science this time, in accordance with public opinion, has condemned it without appeal. It is dead, absolutely dead, notwithstanding some useless attempts at galvanizing after the blow. Its existence was there most ephemeral; scarcely are any of its proselytes now to be found in Paris, and hardly half a dozen in the provinces.

There are some minds which seem naturally to be seized with a vertigo in the presence of novelty, or of an extraordinary unheard-of fact. Every new thing assumes in their eyes the colour of truth; their good sense succumbs before every thing which is invested with an original character. This disposition depends upon the exaggeration of a legitimate sentiment; for who in the present day is not an advocate for the progress of science; who would dare, for instance, to pretend that medicine has reached its utmost limits? and who would wish to retain it within the bounds of ancient traditions? But wise and prudent men are careful, before entering upon a new path, to watch its direction, and to estimate its solidity. When they give a judgment it is with reserve, and with circumspection. This has appeared to us to be the only rational position to take with respect to homœopathy. After having studied it in its books, its journals; after having assisted at its experimentation at the bed-side of patients, and in hospitals; we concluded by pronouncing that Hahnemann is no more than the missionary of a paradoxical idea, destroyed *à posteriori* by observation, ruined by examination, and of which all the value is reduced to a last blow at the doctrine of Broussais.

Homœopathy made itself a favourable argument in Italy. Of its pretended universal application in France, which was the counterpart of its representations in Paris, where it proclaimed the whole of Italy to be converted to its dogmas; that the sovereigns and populations of the peninsula could not dispense with the help of its new materia medica; and that even teaching was imbued with its principles. In

the presence of such facts, asserted with so much audacity, we deemed it requisite to follow up our former investigations, and to submit the doctrine to a new judgment, inasmuch as we might suppose it to be better appreciated elsewhere than in our own country. But we have had the demonstration of the falsehood of these assertions, which were doubtless unknown to the official propagators of the new German theory.

And, in the first place, what is now to be understood as homœopathy? It is perhaps the sentiment of Hahnemann literally expressed in his writings, free from any amalgamation of the medicine of his opponents, which he so strongly denounces. In fact, in his eyes ancient and modern practitioners represent so many homicides, armed with diplomas sanctioned by the laws, exercising with impunity a fatal profession. Is it that exclusive theory, based upon so minute and difficult a symptomatology, with its infinitesimal and almost impalpable doses, possessing nevertheless a miraculous activity? Or is it this same doctrine modified, more tolerant, less forgetful of the scientific genealogy, of which its adepts remember to have seen formerly some real and efficacious effects; which will neither give up bleeding in apoplexy and in pneumonia, nor sulphate of quinine in large doses in intermittent fevers? The few disciples of Hahnemann in France now adopt these mixed ideas; they believe in this medical *juste-milieu*.

Well, whichever of them be meant, Italy rejects at the same time all these gradations; it neither believes in the genius nor in the wonders of Hahnemann, notwithstanding a natural inclination for all that comes from Germany. At Milan, homœopathy constitutes the practice of two or three Austrian physicians. At Lucca, one of its followers is patronized by the Duke, who, however, likewise keeps near him a very orthodox allopathic physician.

We were for a long time curious to know the opinion of Tommassini, this patriarch of Italian medicine, with regard to homœopathy; and the more especially as they arrive at conclusions diametrically opposed—as far as the poles asunder—the one prescribing infinitesimal doses, and the other enormous quantities of remedial substances,

even in the opinion of French physicians. We therefore took an opportunity of asking the Professor of Parma, what was, in his eyes, the medical value of homœopathy. To this inquiry he first of all stated that the same question had been proposed to him in the same terms, in a meeting of the Royal Academy of Naples, and that he had refused to express his opinion in public, inasmuch as he had made no trials of the doctrine; but that at a later period, after having made it the subject of serious examination, he had frankly expressed himself in a discourse to his pupils, while residing at Bologna.

"I do not conceive," said he, "that a method sometimes innocent, but often dangerous, can be adopted. I can understand that, in chronic diseases, in complaints where the beginning of a new treatment can be postponed to the following spring, in which one amuses the patient instead of subjecting him to a curative method, homœopathy is exempt from serious inconveniences—as, for instance, in asthma and other diseases of the same nature; but it does not do in this manner when acute affections are under consideration—pneumonia, enteritis, or when an organ is threatened with gangrene, in which, from Hippocrates down to the present day, energetic remedies have been with reason recommended—bleeding, leeches, purgatives, &c. I would then mistrust a doctrine which has no regular origin, and refuses all paternity."

If any thing more were required to corroborate so explicit a condemnation, we would add that the Italian youth, so animated, ardent, and eager after fresh knowledge, and withal liberal enough not to receive without examination opinions already formed, to whom both the present and future belong, without being burthened with doctrines and practices more or less ancient, did not receive the doctrine of Hahnemann in a more favourable manner than others. We have seen many students and many young professors, but have not known one who had declared himself his follower.

The population also disdained the numerous benefits which it was pretended they would enjoy, and homœopathy was not in this respect more successful in the peninsula than in France. Its course may be likened to that of the practice which thought to ascertain all

diseases by means of an inspection of the urine—and to that of all universal panaceas which appear, and die upon being subjected to trial, as for instance, the hydro-sudopathy, to which a premature end may be predicted. Nevertheless, it must be confessed, that Hahnemann's theory rests upon a more dogmatical principle, perhaps, because its author lived a long time in Germany, a land so erudite, so abounding in synthetical ideas, and evidently for the reason that it arises from the vitalist theory, which is the daughter of the Stahlian *animism*. On the other hand, we must not forget, that for its part it was fortunate in its criticisms directed against the anatomopathologists, whose material conceptions were concentrated to so circumscribed and exclusive a point of view.

In order to omit nothing that may tend to elevate the progressive element of homœopathy, it must likewise be affirmed that by its means allopathy has been brought again to the study of the moral part of man; which study has been much neglected since the close of the eighteenth century. Nevertheless, the medicine of the mind is no less important than that of the body; or, to express the idea better, science should never separate the one from the other in their reciprocal and harmonical relations.

In conclusion, homœopathy has neither been able to introduce itself in Italy, in instruction, nor among the true public (by which is meant the most numerous class): accident cast it, in the first instance, into the centre of some courts. Some princes have favoured it, from the singularity of its practices; but it is a remarkable circumstance, that in a country where the heads of the society are held in immense estimation, it has scarcely been able to make a single proselyte, and its power of propagation has been extinguished by a universal indifference.

At the present time one must search in the recesses of some salons, in order to meet here and there a disciple of Hahnemann. Most frequently they introduce themselves in the wake of an exceptional and extraordinary cure. For us, who are accustomed to believe in the remedial powers of nature, we will not deny the greater part of the facts thus loudly proclaimed, but we will reserve to ourselves the right of interpreting them to those who have learnt by ob-

servation and study, that which science would lead them to conclude from their investigation. All these men, professors and practitioners, ascribe them to regimen, and the conservative power of the living economy: both of which were perfectly recognized by the ancients, those reasonable and enlightened advocates of the *medicine expectante*.

Conclusion.—Homœopathy still exists in Italy, but it is declining and about to disappear: it has neither professorship nor cliniques. Once the ward of an hospital was confided to it at Naples*, but it lost it for reasons of impotency well and duly verified. Reduced at the present moment to the treatment of some chronic diseases, which do not require active means, its hopes rest entirely upon the prepossessions, the prejudices or the caprices, of persons but little capable of judging it.

THE RELATIONS OF THE PHYSICIAN.

(FROM THE GERMAN OF PROFESSOR
HUFELAND.)

[Concluded from p. 485.]

C. Relation to Colleagues.

THE^r relation is two-fold. The first embraces mutual respect, and where that is not possible, let indulgence at least be the principal law of conduct.

Nothing is more difficult than to judge others, but nowhere is it more so than in the practice of medicine. It is therefore unpardonable in the public; but it is revolting to hear physicians, who know the difficulties of the art, and of forming opinions regarding it, judge their colleagues with severity, harshness, contempt; or disclose their faults, and try to raise themselves by lowering others. Oh, that I were able to impress the minds of my brethren with the truism, as forcibly as I am penetrated by it! He who degrades a colleague, degrades himself and his art. For, in the first place, the more the public becomes acquainted with faults of physicians, the more

will physicians become exposed as contemptible and suspicious, and the more will such exposure impair confidence; and confidence in the whole body being diminished, every single one, and the censurers included, will lose a share of it. The public would be less prone to censure the medical profession, and its faults would not be a favourite topic of conversation, if the members themselves did not broach it, and set the bad example. It shows a short-sighted selfishness, and want of all common spirit, when a physician acts in such a manner, and thereby hopes to raise himself, as he degrades others. Further, such conduct is in opposition to the first principles of morals and religion, which command us not to lay bare the faults of others, but to overlook and excuse them; such a character will be more lowered, in the esteem of sensible men, than he whom he endeavoured to degrade; for the detracted loses only as an artist, while he loses as a man; and a bad action is esteemed worse than a bad medical treatment. Finally, they should reflect, that the same measure they apply to others is applied to themselves. He who treats others in a harsh and haughty manner, may rest assured he will be dealt with in the same manner; which is but justice. Modesty in conduct and judgment behoves every one—most of all, a young physician: it will procure him friends, and opportunities for instruction, and promote his eternal interests, as well as his internal improvement. The medical art is still far from that degree of perfection and certainty which would enable us to pronounce sentence on all methods of curing diseases; we do not yet possess a legitimate universal code; every one is still at liberty to form his own views about the human system, and its treatment, provided they are not against reason and experience. Nobody will deny that cures may be effected in quite different ways, and that the apparent contradictions in treatment may dissolve into unity by the various operations of the organism; organic nature is not confined within such narrow limits as are our systems; if it were so, one after the other would not have had its ascendancy, and been applied with success. After all, our experience, and the results rightly derived therefrom, are the only true and

* The account of the trials in the Parisian and Neapolitan hospitals, as also of those instituted in Russia by order of Government, may be seen in a pamphlet (Homœopathy, with notes illustrative of the Influence of the Mind on the Body, 3d Edition), which was the first notice of the subject published in England, and was originally appended to my "Observations on the Continental Medical Institutions and Practice."

constant rules to be followed in medicine; and the longer, and the more sagaciously, a physician has observed the operation of the living organism against the influence of medicaments, the more he has learnt to appreciate the power of the latter, and to use them with adroitness—the more perfect physician he has become. Let every one, therefore, have his own system, his own view of things; let especially the young practitioner feel happy to possess the newest and most finished theory, and to be able to deduct all according to the rules of the school. But none must believe that he is alone in possession of truth; he must respect the opinion of other physicians, particularly of old ones, matured in experience; and he must often admonish himself that he, who believes himself sage, is only on the threshold of art, and that to doubt, and to search for that which is unknown to us, is the surest sign, and, at the same time, the only means, of proficiency. Moreover, it is an axiom in medicine, that the most trifling circumstance is capable of altering the state of things, and their signification, and it is utterly impossible to judge of the medical treatment of another, unless one has himself been present, and has been informed of all the particulars. It consequently follows, that it is always indicative of a deficiency of mind, or of knowledge, or of malignity and bad conscience, in a physician to speak ill of his colleagues, and it behoves the honest practitioner, when he is asked his opinion, to excuse himself from giving it, by saying, that it is impossible to judge in medicine without a most accurate knowledge of the case; or if this is not practicable, to give explanations favourable to his professional brother, which is not a difficult thing to do: thus he will ever respect himself and his profession. As to the second point, the relation of colleagues to the sick, consultation is first to be discussed. In general, the use of consultations, especially when they are numerous, is very problematical. When opinions are alike, consultation is of no avail; when they are diverse, confusion and disorder in the treatment is likely to ensue. It too easily happens that passions and personal feelings get mixed up in a consultation; and what is still worse, a regard for the sick,

and a desire of cure, are but too readily divided and diminished, even in a well-disposed physician, by the interference of plurality. But there may be cases in which consultations are useful, yea unavoidable; as when a disease is very complicated and obstinate, and the physician grows uncertain in his view and his course; when the patient hesitates, and loses confidence in him; when there is great responsibility attached to the treatment, or there intervenes the feeling of a relative, in which we dare not trust ourselves. However, in order that a consultation may prove really useful, the following conditions must be complied with. The consultations must not be numerous, two at most; three physicians are sufficient, and they must not be decided enemies of each other, obstinate partisans of different sects, but be ripened by mature experience, and have a talent to understand, and to enter into, the ideas of others. Their office is principally to discover the di gnostic causes and character of the disease, and then the mode of cure to be pursued. The execution and guidance of a cure, however, must not devolve on a committee, but only on one, the physician in ordinary. The great principle to be observed by every consulting physician must however always remain thus; namely, to have in view nothing but the welfare of the patient, and to that end he must entirely sacrifice his personal feeling, in order that all his powers may unite for a common purpose. If physicians, in their consultations, would be penetrated by this simple sentiment, there never would be altercations, scandalous scenes, and misunderstandings; and consultations would always prove beneficial to the patient. But, on the contrary, physicians often seem to assemble only to show their reciprocal importance, and to discredit the treatment of the ordinary; and instead of harmonising together, to sustain their individual opinions.

Should one be prepossessed of a favourite idea, or of a favourite remedy, the other ought to yield willingly, if there is nothing injurious to the patient in it; to do so will make it apparent that we are not led by caprice, and the more complaisance may we expect in return in the main matter. But should it happen that the opinions and the

plan of treatment can by no means be agreed on, there is no other expedient left, but an appeal to the decision of the patient. He must declare to whom his confidence leans, and the plan of this one must be prosecuted. Nothing is worse than the habit of some patients to consult clandestinely other physicians, besides the physician in ordinary; and nothing is more reproachable than the habit of some physicians to yield to such demands, even to profit by them, to raise suspicions against the ordinary, and to procure admittance for themselves. No honest professional man can act so base a part; he will rebut such a demand, and insinuate to its authors how indiscreet and impossible it is to judge, and to give advice, without consulting the physician in ordinary, and without knowing the plan of cure which he pursues. No one must think that there is no harm in giving a general opinion on a disease and a cure. Such utterances, made without the least bad intention, tend to raise doubts and suspicions in the mind of the sick, and create difficulties and disagreeable embarrassment for the ordinary physician. But should he be convinced that the sick is falsely treated, salvation of the patient being the supreme end of the healing art, regardless of all political and collegial considerations, it must prevail. This end must be attained, and in cases of urgent danger he must immediately do what conscience and duty advise, without farther reference. No physician of a reasonable mind can find fault with such a proceeding. But, on the contrary, when the case is not urgent, he must either propose a consultation, or if the patient will not agree to this, he must clandestinely suggest to the physician in ordinary what kind of treatment would be better according to his opinion. Thus he can comply simultaneously with the obligations towards the sick as well as his colleague, and relieve the one without injuring the other. But when the sick has entirely lost confidence in his physician, and he is resolved to give himself up to the care of another, the latter dare not and cannot refuse to comply, nor can the other take it ill; for the confidence of a man rests with himself, and it is to be respected. Each one must, however, proceed with that frankness and forbearance which be-

comes well-educated gentlemen. When a sick person passes from one physician to another, it is very common, in order to excuse this step, that he speaks ill of the former physician, right or wrong, and alas! it is the policy of the common practitioners to countenance this conduct, and to find the treatment hitherto used erroneous. But it is not so with the honest professional man. He is aware that such conduct is ungenerous towards his colleague, and cruel towards the patient, who will certainly feel double grief, on becoming convinced, that he has lost, not only time and pain, but that his disease has become perhaps worse, and incurable. I cannot conceive how it is possible for a man of sense and feeling to embitter the last days of a sufferer's life by such declaration. Consequently, the treatment hitherto pursued, is to be approved, if not as a matter of politeness, at least in pity for the patient; the doubts of the patient are to be appeased, and the want of success in the treatment attributed to other causes.

SOME OBSERVATIONS
ON THE
MEDICAL TOPOGRAPHY, CLIMATE,
AND DISEASES, OF THE BIGHTS
OF BENIN AND BIAFRA,
WEST COAST OF AFRICA.

BY W. F. DANIELL,
Member of the Royal College of Surgeons of
England, &c.

[Continued from p. 517.]

CAPE St. Paul's is the western extremity of the Bight of Benin, and the commencement of the Slave Coast. It is situated in $5^{\circ} 45' N.$ Lat., and $1^{\circ} 52' 18'' E.$ Long. With the exception of some insignificant elevations in the neighbourhood of Gugligou, Pulley, Whydah, Porto Novo, and Badagry, the characteristic features of the shores are their excessive lowness. They preserve here the same dull and unvarying outline of one vast alluvial and densely wooded forest, extending over an area of at least one hundred thousand square miles, partially irrigated by the Atlantic tides, and intersected by numerous rivers and creeks, whose muddy banks are unceasingly overflowed. At the distance of several miles from the coast, the peculiar odour arising from swampy

exhalations, and the decomposition of vegetable matter, is very perceptible, and sometimes even offensive. The water also is frequently of a dirty hue, with leaves, branches, and other vegetable debris floating on the surface, brought down from the interior by innumerable narrow channels, that empty their turbid streams into the open ocean. The beautiful and undulating scenery of the Gold Coast may be said to terminate at the Rio Volta, eighteen miles beyond Cape St. Paul's, and is succeeded by the unattractive alteration just noticed. In approaching the land from the westward, the soundings throughout the Bight, which are from four to six miles from the beach, gradually shoal from ten to seven fathoms. In the 18th century the settlements on this coast were deemed of the highest value, and were perhaps founded at an earlier period than most others in West Africa, on account of their eligible position and other convenient facilities for the procurement of slave cargoes. This inhuman traffic still flourishes in many of the ports, although of late it has much decreased, being partly suppressed by the vigilance of our men-of-war.

The first commercial establishment in these regions is the fort of Quitta, formerly belonging to the Danish Government, but now abandoned. It has a commanding appearance, with an exterior of dazzling whiteness, as if recently whitewashed, and is surrounded by a quantity of low brushwood, partly cleared away in front. This fortress is included within the limits of the kingdom of Kerraray, and lies about thirteen miles to the eastward of St. Paul's, being erected on a strip of ground between the sea and a salt lake inland, which communicates with the Cradoo Lake by means of a small river (West Lagos), running parallel with the coast. It is now but seldom frequented, other towns located to leeward possessing superior claims to the attention of the trader, with a more enlarged field for speculation. Acquijah and Paurey are two villages distant nine and sixteen miles to the north-east of this settlement. Forty miles from Quitta is the town of Little Popoe, founded close to the water's edge, and where the Dutch had originally a colony. The landing is very difficult of attainment, especially in the rainy

season, owing to the tremendous surf. From these untoward circumstances its position is necessarily damp and unhealthy. The intervening shore between these places is singularly tame and flat, and presents only a few scattered villages that occasionally peep forth from amid a profusion of sombre foliage. In the vicinity of Gugligou, the last of them, four hills adjoin the strand, and are the only local attractions that enliven the dreary waste of wood and water for a long succession of leagues. Twenty-four miles to the eastward of Little Popoe is Great Popoe, preceded by a very low and marshy country, scarcely above the level of the ocean.

This town a few years since was a great emporium for the sale of slaves, from which some thousands were annually exported, chiefly obtained from Dahomey and the adjacent kingdoms. It is situate near the entrance of a small river, that flows from the lake above mentioned, and is unnavigable by vessels of even a moderate tonnage, in consequence of the accumulation of mud and sand that forms an impassable bar. The Portuguese, English, and Dutch, formerly possessed factories here. The natives are a mild, industrious, and quiet people, mostly engaged in trade and agriculture. These towns are not unfrequently confounded one with the other under the vague term of Popoe. A similar description will apply to the land from this port to Whydah, a space of sixteen miles, a slight elevation a short distance from the latter alone interrupting its regularity.

Griwhe, Grewhe, or Whydah, is in 6° 19' N. Lat., and 2° 5' E. Long., and is at present the principal sea-port town of Dahomey to which European traders resort, being the main outlet to the fertile and productive district of the same name. The appearance of the country in the vicinity of the town resembles the American prairies or savannahs, and like them is low, flat, with occasional knolly elevations. The soil, dark and loamy, is clothed with lank grass and wooded islets, which are well stocked with deer and game. Its climate has been supposed to be more congenial to the constitutions of *unacclimated* than most of the localities in this Bight; but it is, in point of salubrity, incomparably inferior to our

possessions on the Gold Coast. Prior to 1727 it was an independent state, in which year it was invaded and overcome by the warlike sovereign of Dahomey, Guadjá Trudo. Since then it has, in conjunction with Ardrah, become annexed to the extensive provinces of that spacious empire. The succulent and sweet-flavoured tropical fruits may be procured in all these towns in greater or less abundance, but more particularly in their surrounding territories. Pine-apples, oranges, guavas, limes, melons, bananas, &c. grow in wanton exuberance in the environs of Whydah, and would tempt the palate of the most fastidious by their exquisite fragrance. Among the plants indigenous to Whydah may be mentioned the *Saccharum officinale* (sugar cane), *Ocymum basilicum* (common basil), *Amomum Grana Paradisi* (Malagetta pepper), *Parinarium excelsum* (African plum), *Panicum miliaceum* (millet), *Lycopersicum solanum* (love apple), *Indigofera tinctoria* (common indigo),* &c. The soil of the interior is a rich argillaceous clay, of a reddish tint, intermixed with siliceous particles. The West African Company had latterly a fort at this place, but it is now abandoned and in ruins.

Porto Novo, the sea-port of the kingdom of Ardrah, is thirty miles from Whydah. The minor towns Appee and Jackin, the former three or four miles inland, and a solitary hill (Mt. P. Iayer), near the latter, are the only objects worthy of note, the intermediate coast still affording the same monotonous aspect. The capital of this territory is also termed Ardrah, and is built on the banks of a small river, that unites with another running into the Cradoo Lake.

* There are several species of the *Indigofera* employed by the natives, not only for their medicinal properties, but also for the purposes of dyeing. Those commonly administered by the native practitioners for the cure of diseases, are the *I. tinctoria*, *I. birsuta*, and *I. euncaphylla*, &c.; but it is often difficult to determine the correct species from the mutilated specimens that are submitted for examination. The Eboes appear to use the *Indigofera euncaphylla*, abundantly found in the interior, which they term *Né* (probably a corruption of the Arabic word *N. e'*) in enteric affections, and as a vermifuge. According to Forskal, the *I. tinctoria* is much resorted to in Northern Africa for its anthelmintic powers. In his *Flora Egyptiæ Arabica*, he states it to be the *Nile* of the Arabs, and that it is exhibited "*semina cum oleo sesami et sale ammoniac mixta mane assumpta, Tania ex-pellunt. Diæta erit: aqua per triduum abstinere, alium cibum non edere, nisi panem, potus coicæ permittetur.*"—Page 138.

It enjoys a population of above eight thousand, who are a well-formed, active, and enterprising race. I may here remark, that the nomenclature of several towns, not only on this, but also on the Gold Coast, has been evidently derived from an oriental source. Ardrah, with one or two other towns, may be satisfactorily cited as the most obvious examples.

Badagry is a moderate-sized town, with a population of ten thousand. It is situate three miles from the shore, on the western branch of the river Lagos, twelve miles to the eastward of Porto Novo, and is not much resorted to, unless by the Portuguese and French. A second hill (Mt. Badagry) may be observed near it. A sandy strip of land, covered with a thick sward of grass, intervenes between it and the beach; and the suburban buildings are partially concealed by young thickets of evergreen shrubs. A Wesleyan missionary school has been recently established here, for the education and conversion of the natives, under the control of the Rev. T. Freeman, the indefatigable superintendent of the missions at Cape Coast Castle, &c. When the slave trade was at its zenith, the Portuguese erected no less than five factories at this place, and the sale of human beings was carried on to an almost incredible amount. The upper layer of the soil in the circumjacent country has been stated to consist of sand, incorporated more or less with a reddish marl, on which it is usually based.

The unfortunate Capt. Clapperton with Richard Lander, set out for Sakatoo from this town in December 1825, and the brothers Lander followed this track in 1830, in their first expedition into the interior. The sovereign of Badagry professes allegiance to that of Eyeo or Katunga, a metropolitan town lying some distance beyond the eastern range of the Kong mountains. After passing a low thickly wooded shore to the extent of thirty-six miles, studded by a continual succession of picturesque villages, the river and port of Lagos successively engage our attention. The river Lagos, but three quarters of a mile in width, forms the estuary of the Cradoo Lake, and from its shallowness is perfectly inaccessible to craft of any burthen. It is divided into two diverging streams, named

East and West Lagos, the former running parallel with the shore from three to four miles distant, flows into the Rio Formosa; the other merges in a large expanse of water near Whydah. Adjoining its embouchure, situated in 6° 24' N. Lat. and 3° 22' E. Long. is a small island, on the northern extremity of which the town of Lagos is founded. This place enjoys a lucrative commercial intercourse with the circumjacent countries by various creeks, whose tortuous branches meander in every direction, particularly towards Dahomey and Benin, which are from sixty to ninety miles to the eastward of it.

The diseases of the inhabitants of the Slave-coast differ but little from those observed in the numerous rivers of the Bights more to the southward. In the prædial and elevated inland districts they are less prevalent than in the maritime towns and villages, and moreover are not characterized by that asthenic type which accompanies those morbid affections that occur in the latter localities*. In Yaniba, Benin, and a few of the neighbouring kingdoms, circumcision is performed on both male and female very early in infancy. Mr. Dalzell states, that this operation "is universally practised among the Dahomian subjects, but not at such an early age as among the Jews; the time of submitting to the operation being left to the boys themselves." A very curious custom, mentioned by this author, still exists among the younger females: "Prolongatio videlicet artificialis laborum pudendi, mammæ papillæ simillima."†

Cradoo Lake is about fifty miles in length, and from four to seven in breadth. Several tributary streams empty their waters into it, after wandering through a series of fertile districts, and serve as the most easy medium for the conveyance of the native merchandise from one remote market to another. Its banks are covered by numberless flourishing villages, the inhabitants of which are solely devoted to agricultural and mercantile pursuits. Cradoo, the capital of these populous regions, lies in the Jaboo country, thirty six miles from the outlet of the lake. Lake

most trading depôts in this Bight, the human species still remains one of the staple commodities of barter. The soil of the interior is light and sandy, and when denuded of its heavy timber and underwood is richly productive.

Thirty miles to the eastward of Lagos is the petty village of Palma, and twenty-one miles to the eastward of it is the town of Oady or Oddy, beyond which detached clusters of mud habitations are occasionally perceptible, located on the verge of the sandy beach, and mostly concealed by the foliage of the adjacent woods. The general aspect of the coast from this portion to the Rio Formosa, a distance of thirty miles further to leeward, resembles the regions previously described, and is equally insalubrious.

CASE OF MALIGNANT OR HÆMORRHAGIC SMALL-POX.

By JOHN SNOW, M.D. London.

Fellow of the Royal Medical and Chir. Society.

(For the London Medical Gazette.)

THE following case from my note-book, of a form of small-pox which, I believe, is happily now very rare, is, I think, not devoid of interest; and will be still less so, if examined in conjunction with the "Case of Purpura Hæmorrhagica, probably arising from variolous contagion, by N. Adams, Esq." in the last number of the MEDICAL GAZETTE, which occurred in the country nearly at the same time as my case, and which resembles it in several particulars.

I was called at 7 o'clock, on the morning of Saturday the 8th of June last, to a boy named Cannell, living at No. 2, Chapel Place, Crown Street, Soho. He was a fine stout boy, seven years of age, but had been affected with asthma from his birth. His brother, aged 5, was labouring under small-pox in the same room; they were of the distinct kind, and in the maturative stage. Neither of the children had been vaccinated. The subject of this case took ill on the Thursday morning previous to my seeing him, with pain in the back, and fever. On the evening before my visit, an eruption appeared on the skin, and he became delirious; afterwards he had bleeding from the nose. He

* Fetish and other superstitious ceremonies constitute the remedial treatment employed by the native doctors.

† History of Dahomey, 1793. Introduction, page xviii.

was delirious all the night, and was insensible of what was said to him, and vomited a liquid mixed with blood. I found him in a muttering delirium, incapable of being roused, although he resisted any attempt to give him drink. He was vomiting almost constantly small quantities of blood, and of a thinner liquid, apparently serum, tinged with blood. The face and neck were swollen, and of a purple colour—were occupied, in fact, with one large vibex. There were other vibices on the body, and the rest of the trunk and extremities was spotted with numerous petechiæ, many of which had a lightish coloured spot in the centre, and appeared like pimples till they were touched, but there were only a very few on the trunk which could be felt to be a little elevated. The skin was hot, and the pulse frequent, small, and feeble; the tongue was coated with a brown fur, and the rest of the interior of the mouth was of a bluish white colour; he had passed motions in bed; cold applications were directed to the scalp denuded of hair, and sinapisms to the legs.

He was visited again in three hours; the vomiting of blood continued; the breathing was stertorous, and the pulse almost imperceptible. He died in half an hour more.

I made an examination of the body eleven hours after death, with the assistance of my friend Mr. Marshall, of Greek Street. The vibices and petechiæ remained as before; the scalp was very vascular, and blood flowed from it when cut; the veins on the surface of the brain were much distended, and the pia mater dipping in between the convolutions was much engorged, and there were little spots of extravasated blood in this situation. The red dots were found to be rather more numerous and large than natural on slicing the brain; there were one or two drachms of clear serum in each lateral ventricle, a little in each of the other ventricles, and a drachm or two at the base of the brain; the lungs were extensively emphysematous, they did not collapse on the chest being opened, but, on the contrary, rather bulged out, and many of the lobules were paler and more prominent than the rest. This emphysema of the air cells was most extensive at the lower part of the lungs; there were a few

partial adhesions of the pleuræ, and the lungs were engorged with blood, as were the right cavities of the heart, which was healthy. The stomach contained a little bloody liquid, and all over its inner surface were dark purple spots averaging about the size of a pea, and situated about half an inch apart. They proved to be small portions of blood extravasated beneath the mucous membrane; this condition did not extend to the intestines. The fæces in the small intestines were of a very dark colour, most likely from the presence of blood. The bladder was empty, and the viscera not mentioned were in the normal condition.

The row of small dwellings, in one of which this boy lived, are damp and ill ventilated, and all the illness I have seen in them has been more severe and intractable than in the rest of the neighbourhood. I have treated two cases of sporadic cholera there, as bad as any cases of the epidemic disease which I have known to end in recovery; and one case of purpura hæmorrhagica with inflammatory symptoms in a child about five years of age, which I understand did not recover from the illness.

Frith Street, Soho Square,

ANALYSES AND NOTICES OF BOOKS.

“L’auteur se tue à allonger ce que le lecteur se tue à abréger.”—D’ALEMBERT.

The Anatomy of the Arteries of the Human Body, with its applications to Pathology and Operative Surgery, in lithographic drawings; with practical commentaries. By RICHARD QUAIN, F.R.S. Professor of Anatomy in University College, and Surgeon to University College Hospital. The delineations by JOSEPH MACLISE, Esq. Surgeon. Part xvii. London: Taylor and Walton.

WE congratulate Prof. Quain on the completion of this very excellent and beautiful work; a work justly deserving a place in the library of every surgeon conscientiously devoted to the duties of his profession. The delineations are no less distinguished for fidelity of detail than artistic effect. The part before us comprises seven plates; six refer to the arteries of the leg and foot; the remaining plate illustrates the

ordinary disposition of the arteries of the brain and spinal cord, and some peculiarities of the former.

The author, impressed with a belief that the difficulties which have often occurred in the performance of those surgical operations in which the larger arteries are concerned, have arisen in great part from want of sufficient acquaintance with the differences in anatomical disposition to which these vessels are liable, not merely as regards the deviations in the origin of large branches, but other peculiarities affecting the length, position, or direction of the vessels, was led to a minute study of the subject. With this view the bodies which were received during a series of years for the study of anatomy into the School of Medicine in University College, were examined with more or less attention.

"These bodies, to the number of 1040, were, with rare exceptions, so inspected with reference to the subject of my inquiries, that anything very unusual could not escape notice; and, in order to insure accuracy, when other occupations allowed, the arteries were carefully examined and their condition noted at the time,—attention being always particularly directed to those vessels and to the points in their history which seemed to be of importance in the practice of surgery.

"This detailed investigation was continued until the number of cases observed appeared such as would afford grounds for fixing what should be considered the most frequent or standard conformation of the vessels, and for forming at the same time reasonable conclusions both as to the limits of the deviations from that standard and the relative frequency of their occurrence.

"While the observations thus made were written down, drawings were obtained of all the important peculiarities which presented themselves, and when it was practicable the preparations were preserved.

"The varieties in the arrangement of the blood-vessels thus noted grew, as may be supposed, to be very numerous; but instead of difficulties multiplying with the number of observations, it was usually found that as the facts accumulated, the transition

from one state to a very different one ceased to be abrupt or without method, for others from time to time interposed which served to link them together."

These observations the author intended originally for the benefit of his class, but as their number and connexion seemed likely to render them more extensively useful, he very wisely resolved to publish them.

It was found, however, that their utility would be very limited, unless a full history of the arteries, with adequate delineations, were annexed. Accordingly in the present work the arteries are depicted as follows:—

"1st According to their most frequent arrangement, without the accompanying veins. 2ndly. They are shown in connection with the larger veins and the nerves. 3rdly. The deviations from that which has been taken as the standard because the most frequent condition of the arteries, are illustrated in a series of sketches. 4thly. Such peculiarities of the veins, and occasionally of the nerves and muscles, as appeared likely to be of importance in surgical operations, are represented on a reduced scale.

"The letter-press, besides an explanation of the drawings and remarks on them, contains—A Series of Tables, showing, in a considerable number of cases, the condition of the arteries as to some of the points of most importance in their anatomy. A connected view of their anatomical history,—the details being arranged in systematic order. And Practical Commentaries: which consist, for the most part, of inferences from the facts previously set forth, and their application in performing surgical operations."

A Thermometrical Table on the Scales of Fahrenheit, Centigrade, and Réaumur. By ALFRED S. TAYLOR, Lecturer on Chemistry, &c., in Guy's Hospital.

WE think the profession very much indebted to Mr. Taylor for this most useful table. It is designed to obviate the necessity for those perplexing calculations so often rendered necessary by the employment of different methods of graduation in England and on the Continent. It ranges from 13° to 374° Fahrenheit, from -11° to +190° Centigrade, and from -9° to +152° Réaumur; arrange

which comprises all the most remarkable phenomena connected with heat. The facts connected with temperature, placed on the scale, relate to Climatology, Physical Geography, Chemistry, and Physiology. In compiling this table, which has occupied the occasional leisure of four years, Mr. Taylor has invariably acted upon the principle of selecting the best authorities. Many of the facts he was enabled to collect or verify by personal observation, and some of the chemical phenomena have been derived from direct experiment.

The Medical Guide and Almanac for
1845.

THIS comprehends the latest regulations of all the licensing medical corporations, with a list of their officers, the metropolitan and provincial schools and hospitals, and the universities and medical schools of France and Germany. It may be regarded as a very useful book of reference for young men commencing their studies, for those about to enter the public service, or for those who intend to resort to the continent in quest of further knowledge.

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medice tueri; potestas modo veniendi in
publicum sit, dicendi periculum non recuso."

CICERO.

THE REMEDIES PROPOSED.

WHILE all parties seem convinced that it is high time an improved system be adopted for the regulation of the medical profession throughout the United Kingdom, a want of unanimity prevails as to how that may be best accomplished. One party contend for the supremacy of the Royal Colleges, for allowing quackery of all sorts to remain unmolested, and for letting the Bill pass in its present form. Another party object to certain enactments in the Bill, but evince a sense of gratitude

to Sir James Graham for its introduction into Parliament. They approve, for example, under certain modifications, of the proposed Council of Health and Medical Education; of a public annual registration of all qualified members of the profession, provided that be rendered compulsory. They urge, however, the expedience of a summary process of punishment for individuals who shall falsely pretend they are registered, or assume any name or title whatsoever, implying that they are practitioners in medicine or surgery; they might also add obstetrics. A third party, on the other hand, maintain that the Bill is not calculated to benefit either the public or the profession, and demand its total withdrawal. They entertain the opinion, that nothing short of incorporation of their body will be of any avail; and this they regard as constituting the sole and indispensable measure of reform. Establish us by Royal Charter, say the latter—give us an independent College of our own—and we shall be satisfied; not otherwise. Under this new *régime* the existing Colleges of Physicians and Surgeons would, it is supposed, be ere long eclipsed, and swept away as useless incumbrances. How, indeed, could these institutions be expected to survive in the presence of a University embodying nineteenth-twentieths of the medical practitioners of the realm?

We have been led to form the tripartite division above mentioned, from a very attentive perusal of the various documents that have lately appeared. From all we can learn, what might be termed the moderate party, or that classed under the second head, embraces a very considerable proportion of the leading medical men throughout the provinces.

With them we heartily concur as to

the urgent necessity for making the laws more stringent, and more easily available, against all unqualified and uneducated persons practising in any branch of the healing art. Indeed, we formerly expressed an opinion that if the restrictive clause in the draft of the bill now before parliament were somewhat extended and more distinctly defined, the object would be attained.* The pernicious consequences of the no-restriction system are amply demonstrated in the American States of the North. In the city of New York, for instance, where any shoe-black may arrogate the title and functions of a doctor of physic, things have come to such a pass, that scarcely a practitioner of honourable feeling is found willing to enter the lists with the disgraceful competitors he must needs encounter. There, of a truth, the profession is in a most degraded condition. In fact, with the exception of some four or five physicians of established reputation, a great proportion of the practitioners of that populous place are ignorant and boastful pretenders, alike guiltless of education and of principle. We have been informed by an intelligent eyewitness, that the sittings of its Medical Society more resembled a bear-garden than a convention of members of a liberal art. The ordinary qualification to ensure practice among the mass of the community is to establish an apothecary's shop in some frequented street, and then to puff off a nostrum or two. By the help of such appliances impudence and effrontery rarely fail to succeed in gaining the credulity of the public, and ousting the regular practitioner. We are told that an empiric of this stamp realized a larger fortune than ever fell to the lot of any member of the faculty in that city. As a natural result of so debased a state of things, the adultera-

tion of drugs is carried on to an unbounded extent. Every article in the materia medica of any value is notoriously sophisticated.* In the southern states of the union, namely, Carolina, Georgia, and Louisiana, where some collegiate control exists, the profession is, we believe, altogether on a better footing.

Let us now turn from "a republic unequalled in the annals of the world for the freedom of its institutions"† to one where the spirit of liberty is not permitted to soar on such eagle pinions, though situate within the same hemisphere—we allude to Mexico. In its capital, made up of gorgeous palaces, and mud-built hovels, containing a population of 180,000 souls, irregular practice is unknown, and little or no encouragement is given to the sale of quack medicines. No one is allowed to officiate in the treatment of disease who has not previously passed a rigorous examination of four or five days' duration by the professors of the University. A Board of Health, the *Cuerpo de Sanidad*, composed of able men, presided over by a minister of state, forms the head of a medical police for the kingdom. Its duties are clearly defined. It takes care that no individual shall exercise the vocation of a physician, surgeon, or accoucheur who is not duly qualified and *registered*. The chemist (*boticario*), whose duty is confined to the preparing, compounding, and dispensing of physic, is also compelled to undergo an examination before he can obtain the requisite license for carrying on his business; he is at all times amenable, in common with medical men, midwives, and dentists, to the jurisdiction of the above board. In

* Salts of morphia have been met with in commerce, containing ninety-nine and a half in the hundred of foreign matter; nor is it by any means uncommon for a practitioner to vaunt his administering calomel in the dose of a hundred grains and upwards.

† Daniel Webster.

* Medical Gazette, Jan. 10, 1845.

like manner, all questions relating to the public health, to the prevention or treatment of epidemics, to hospitals for the sick and insane, come within its cognizance.

The whole system works exceedingly well. Medical men are held in just estimation, and liberally rewarded for their services.

Nothing, indeed, can exemplify in a stronger light the hazard of removing all restraint than a comparison of the state of the profession in the United States and in Mexico. In the former country it is pauperized and of no repute, in the latter it is honoured and prosperous.

BATHS FOR THE MILLION; BATHS FOR THE INDIVIDUAL.

CLEANLINESS has long been admitted to be next to godliness; and ever since we have seen Lord Malmesbury's Memoirs, just published, we have had greater sympathy with George IV. than we can pretend to have had before. The Princess Caroline, it seems, prided herself upon the rapidity of her toilette; she huddled on her clothes anyhow, and without even the merest sham application of soap and water as a preliminary. The special ambassador had actually to explain to the princess and her woman the propriety of anticipating the dressing by proper ablutions, by a *toilette de propreté*; it was only after this that he succeeded in having the princess presented to him in the morning, '*well washed all over!!!*' We presume there is not a princess in Europe, at the present time, who would require such a lesson as Lord Malmesbury felt it his duty to read to the Princess Caroline of Brunswick, not quite half a century ago. There are many, however, who are neither princesses nor princes, who will not be the worse of a word of admonition on the subject of his *toilette de propreté*—by which is to be understood something more than even the most liberal application of water, whether hot or cold, to the face and hands in the morning. We wot of no greater luxury than a thorough sponging on getting out of bed; next to temperance

in all things, indeed, we look on this, or something akin to it, as the greatest preserver of health; it is almost a substitute for that indulgence in country air and recreation for a certain portion of the year which all who live "in crowded cities pent" so anxiously sigh after, but which the great majority of the community, and we of the medical profession especially, sigh after in vain.

Any improvement on the means of enjoying the cheap and wholesome luxury of cold water to the general surface of the body in the morning, we look on as a boon conferred on society, as another instrument for prolonging human life. The japanned or painted tray that is now so commonly sold in the shops, and a good sponge, are the simple implements; and they are good so far as they go. Until lately, the only substitute for them was the somewhat costly and often cumbrous and otherwise inconvenient shower bath. Now we have the shower bath made portable, reduced to such dimensions that it may be put into a small box or portmanteau, and carried with the traveller wherever he goes. Our readers must surely have observed in the hardwaremen's shops, a figure, with dripping locks, and dimly seen through the shower that is falling from a somewhat elegantly shaped vessel held over the head? This is a representation of a portable shower bath, the contrivance of an ingenious gentleman of the name of Hazard, which we are anxious to introduce to our readers. The ordinary sponging tray, and this apparatus, enable us to command a shower bath at a minute's notice at all times, and make us independent of more costly and cumbersome contrivances. We have heard a great deal lately of baths for the common people; in our zeal for the mass, let us not forget the individual. And now that the year is turned, and "Socrates is no longer seen white with the snow," let us recommend those among our readers who have not yet indulged in the luxury of tepid or cool or cold general ablution, to commence forthwith to add one, two, or three years to the absolute length of their lives, and a vast sum of innocent enjoyment to their pleasures, by the daily use of Mr. Hazard's portable shower bath.

MOVEMENT IN THE PROFESSION.

A MEETING of general practitioners resident in Brentford and the vicinity, was held upon the 21st current, at the Royal Hotel, Old Brentford; Dr. Day, of Acton, in the chair. The Bill of Sir James Graham was wholly repudiated. It was maintained that the interests and efficiency of the general practitioners would be best promoted by incorporation of their body, so as to include all who, at the time of granting the charter, are legally qualified; and that the Society of Apothecaries deserve the confidence and support of the profession for their conduct in reference to the proposed charter. An honorary secretary was to be appointed, and a deputation to wait upon the county members to urge their strenuous opposition to the above bill in parliament.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Tuesday, January 14th, 1845.

MR. STANLEY, President, in the Chair.

Three Cases of Hard Circumscribed Tumors in Muscle, disappearing under the influence of the Iodide of Potassium. By THOMAS TATUM, Esq. Surgeon to St. George's Hospital, and Lecturer on Anatomy.

THE author relates three cases of tumors in the substance of muscle, supposed to be the effects of chronic inflammation, and deposition of coagulable lymph between the fibres. In each of the patients, the swellings were situated in the sterno-cleido-mastoid muscle; and in one, a similar tumor afterwards formed in the clavicular portion of the pectoralis major muscle, but which was distinguished by being of a bony hardness, and apparently connected with the periosteum of the clavicle. The author is of opinion, that had the progress of the disease not been interrupted early, ossific deposit would probably have taken place in the tumors, and the muscular structure been converted into bony tissue. He draws particular attention to the decided influence which the iodide of potassium had in removing the tumors, and the inefficiency of various other remedies which had been previously tried.

Mr. Cæsar Hawkins had found in these cases that the inflammation was not always, though frequently, confined to the muscles. It sometimes implicated the cellular tissue.

Sir G. Lefevre inquired the experience of members in the use of iodine. He had seen a case in which the use of iodide of potassium for secondary syphilis, in doses of ten grains three times a day, for four or five months, was said to have produced the loss of virile power. The testicles were not absorbed. He had heard of cases in which iodine had affected the mammae, but not the testicles.

Mr. Cæsar Hawkins observed, that notwithstanding the constant employment of iodine and its compounds by medical men, he had never seen or heard of a case like that alluded to by Sir G. Lefevre.

Mr. Curling had not seen tumors similar to those described in the paper affecting the sterno-mastoid muscle. He had, however, in this muscle, seen indurations resembling cartilage, occurring two months after birth, and, by their influence, completely fixing the head. These tumors had given way under the use of mild liniments.

Mr. Acton had witnessed the extensive employment of iodide of potassium by M. Ricord, and had himself employed this medicine in a great number of cases. No such effect as that mentioned by Sir G. Lefevre had ever come to his knowledge. Iodide of potassium sometimes produced pain in the stomach from being given in too small a quantity of liquid. He prevented this effect by giving it in a large quantity of water. This medicine also occasionally produced a metallic taste in the mouth, and a spongy and hæmorrhagic condition of the gums.

Mr. Snow mentioned the case of an infant in which, in consequence of suddenly twisting the head round, a tumor, with tenderness, arose in the course of the sterno-mastoid muscle. The swelling remained for ten or fourteen days, but was removed by mild lotions and liniments.

SPECIFIC GRAVITY OF URINE.

ON A VERY READY AND EASY MANNER OF ESTIMATING THE QUANTITY OF SOLID MATTER HELD IN SOLUTION IN ANY GIVEN QUANTITY OF URINE OF A GIVEN SPECIFIC GRAVITY (AT 60° FAHR.)

To the Editor of the Medical Gazette.

SIR,

AT a time when the morbid conditions of the urine are attracting much attention, and when it is believed that important inferences may be deduced from ascertaining the amount of solid matter excreted from the kidneys in a given time, as compared with the amount so discharged in health, it seems a matter of some importance to call the attention of the profession to a very simple and accurate method of arriving at this result. My purpose, in this letter, is to call attention to the Table constructed by Dr. Henry, in which

he gives the solid contents of a wine pint of urine, of specific gravity varying from 1020 to 1050—a table, I may remark, which has received the sanction of Dr. Prout, since he copies it at page 27 of his work on the Nature and Treatment of Stomach and Urinary Diseases; and also of Dr. G. O. Rees, who not only quotes it at page 147 of his book on the Analysis of the Blood and Urine, but adds, that he “has had occasion to test its correctness, and can recommend it as calculated to afford most satisfactory results.”

Now if this table be examined, it will be found that there is an increase of solid contents in each wine pint of urine, corresponding to the increase of one degree of specific gravity of exactly 19.2 grains; or of 1.2 grains of solid matter in each ounce for every increase of one degree of specific gravity. Hence a very simple process will give us the amount of solid contents in urine of any given specific gravity, say of 1025; for we have only to multiply the constant quantity 1.2 grains by 25 (making 30 grains), to give us the solid contents of one ounce, whose specific gravity is 1025; and this again by the number of ounces voided in any given time, say 40 ounces (making 1200 grains), to give us the whole quantity of solid matter dissolved in the urine passed in that time. This rule will be found on trial to give results so nearly coinciding with those of the table (the error is constantly just 1.6 grain in excess in the wine pint), it is so easy both to recollect and to apply, and so much more convenient than reference to a table not always at hand, that I shall make no apology for trespassing on your pages, with the view of bringing it under the notice of your readers.

I remain, sir,

Your obedient servant,

ALGERNON FRAMPTON, M.D.

Physician to the London Hospital.

29, New Broad Street,
Jan. 21, 1845.

FORM OF GALVANIC APPARATUS.

THE LONDON MEDICAL GAZETTE,

BEING A
WEEKLY JOURNAL

OF
Medicine and the Collateral Sciences.

FRIDAY, FEBRUARY 7, 1845.

NOTES OF A LECTURE ON PHLEGMONOUS AND PHLEBITIC OPHTHALMITIS,

By DR. W. MACKENZIE,

Of Glasgow.

WE lay aside the term *Ophthalmia*, and adopt *Ophthalmitis*, when the whole eyeball, or, at least, all its most important structures, are at one and the same time, and from one and the same cause, affected with inflammation. I have already explained to you, that not unfrequently inflammation, attacking at first only one of the textures of the eye, spreads from structure to structure, till the whole are involved, and the functions of the organ destroyed; but this is not the sort of case I am now about to describe. The disease which I have now in view much more speedily involves the whole globe of the eye, and also the parts around the eye, especially the ocular capsule, which I formerly shewed you surrounding the ball, and giving passage to the six muscles which are inserted into the sclerotica. The ophthalmitis I have now in view depends on a number of different causes, and thus we might distinguish, if we chose, various subspecies of the disease; but the two most prominent are, injuries of the eye, and the circulation of purulent matter in the blood. Arising from the former cause, the disease has been termed *ophthalmitis phlegmonosa*, or *traumatica*; and from the latter, *ophthalmitis phlebitica*. I have seen some cases, in which the cause was altogether obscure, the disease arising apparently spontaneously; and such we might regard as *idiopathic*.

The disease in question has been known under various other names, besides that of ophthalmitis. It is the *ophthalmia interna propria sic dicta* of Beer; the *phlegmon oculaire* of Dr. Roguetta. Resembling a paronychia in the tense state of the inflamed

parts, and the severe pain by which it is attended, the disease has been styled improperly *panaris of the eye*—panaris, you know, being a corruption of paronychia.

Stages of ophthalmitis.—An attempt has been made to divide the symptoms into three stages, but I doubt the accuracy of the division. The *first* stage is supposed to be one of pure inflammation, denoted chiefly by pyropsia, and extending from the commencement of the disease till the retina is deprived of sensibility; the *second*, is that of protrusion of the eyeball, and of suppuration in and behind it; the *third*, that of spontaneous rupture of the ocular capsule, or of the eyeball, or of both; but before this happens, the case often terminates fatally, especially in phlebitic cases.

Symptoms.—If the *first* stage is to include what we observe before the eyeball is protruded from the orbit, the following are amongst the symptoms of that stage. There is slight external redness; the conjunctiva being rather oedematous than inflamed, or affected with what some have called a *white chemosis*. The aqueous humour presents a muddy appearance, or is even tinged with blood. The fundus oculi appears reddish. The iris changes its colour from inflammation, the pupil becomes somewhat contracted, and the disease is apt to be mistaken for iritis. The capsule of the lens sometimes becomes opaque, in other cases continuing transparent. There is generally severe pain in the bottom of the eye, and in the orbit; pulsating pain, exactly as in intense whiteloe; the pain extends to the forehead and temple, and is accompanied by a feeling of burning heat, tension, and fulness, as if the eye could not be contained within the orbit. There is much intolerance of light, and a sensation of shining flaming spectra before the eye. This by and by subsides, the retina becoming insensible, from change of structure, or from the pressure of the purulent matter which is thrown out on both its surfaces. For a time, pressure on the retina causes photopsia or pyropsia, but as the

pressure increases it renders the retina totally insensible.

The total loss of sensibility of the retina may be regarded as a sign of internal suppuration having taken place, but the most striking symptom of the *second* stage is the protrusion of the eye. You would say, the eye is very much swollen, but this is a deception. You would say, were you not acquainted with the fact, that the eye was prodigiously enlarged, that it was almost as big as the fist, but I tell you, this is a deception; for after death, you find the eye, which seemed so greatly enlarged, nearly, if not quite, of its natural size. The eye is pressed forwards by an effusion into the cavity of the ocular capsule, and in this state of exophthalmos, covered as it is by a chemosed conjunctiva, the upper eyelid stretched tensely over it, and the lower eyelid everted, it has every appearance of being in itself greatly enlarged. It is also excessively hard to the touch, as if some fluid was pent up within it, much more in quantity than it contains in the natural state. This is partly true, but the internal effusion is not the sole, nor the chief, cause of the excessive hardness and tenseness of the eyeball. The effusion within the ocular capsule is the chief cause of this symptom, as well as of the protrusion of the eye. This symptom, of protrusion, sometimes occurs early in the disease, sometimes late, and not till the interior of the eye is disorganised and vision extinct. It is right that you should be aware, that there are diversities in the progress of the disease, and even in the order in which the symptoms follow each other. There is an involuntary fixedness of the eye in this stage, the state of pain and swelling rendering any contraction of the muscles unavailing, or perhaps impossible. You cannot even push it from side to side, in the orbit, it is so completely fixed. The conjunctiva continues greatly swollen, and what is a singular thing, and which I have never seen except in cases of phlegmonous or phlebitic ophthalmitis, the conjunctiva is covered, especially that portion of it which lines the lower eyelid, by a layer of coagulable lymph, which you can peel off like a membrane, and which by and by is again formed. This is met with both in the traumatic and in the phlebitic cases, and serves to show the analogy existing between these two varieties of the disease. If the lens and its capsule have continued transparent, (for I have already told you the lenticular capsule sometimes becomes opaque in the first stage of the disease,) you may sometimes observe the vitreous humour of a grass-green colour, the result of pus effused within the hyaloid. The iris is now seen to advance towards the cornea, and matter is plainly deposited in the posterior and anterior chambers.

The whole eye is now full of purulent

matter, and so is the ocular capsule: and if life is prolonged, the disease, unless interfered with by art, passes into the *third* stage. The matter makes its way out, exactly as the matter of a whiteloe, after immense suffering, will make its way to the surface and escape. The bursting of the eye, or of the capsule, is a means of saving the life of the patient, against whose recovery the chances are very great, if the disease is left to itself, and no spontaneous evacuation of the matter takes place.

Now, sometimes the cornea becomes infiltrated with matter, sloughs, and bursts; and this is the only disease of the eye in which I have seen a distinct leathery slough separate from the eye—the cornea, in fact, like a bit of white leather, which has been steeped in water. You often hear, indeed, of sloughing of the cornea, but what is called sloughing is merely destruction by ramollissement and ulceration, not actual separation of the part in a mortified state, as you sometimes see it in ophthalmitis. The evacuation of the eye follows the separation of the cornea, and the eyeball becomes atrophic. In other cases, it is the sclerotica which gives way, and this generally into the cavity of the capsule, which, bursting in its turn through the conjunctiva, allows a large quantity of matter to escape. In a third set of cases, the capsule alone gives way, the eye remaining entire, but so similar is this event to bursting of the sclerotica, that they are apt to be confounded. You see an aperture through the conjunctiva discharging pus, and you put a probe into it, and the probe seems to pass fairly into the cavity of the eyeball, while it may have gone only into that of the ocular capsule. If the eye retains anything of its natural appearance—its natural size and shape, and much more if it retains any sensibility to light, depend on it the eye has not burst, the capsule only has given away.

The constitutional symptoms which attend ophthalmitis are of variable intensity, but in general they are very severe. The patient is affected with rigors, anxiety, insomnia, delirium, and sometimes with convulsions, especially if the case is about to terminate fatally. In the commencement, the pulse is full and throbbing; in the later stages of the disease, it is small, weak, and very quick.

Terminations.—The disease terminates in different ways. A perfect recovery is very rare indeed. Sometimes the termination is in amaurosis, the form of the eye remaining natural, the pupil contracted, the lenticular capsule opaque, the retina insensible. In such cases the treatment has been partially effective. The termination may be in suppuration and rupture of the eye, or of the capsule, or of both. In this case, the eye ultimately collapses. Death is no uncommon termination of ophthalmitis, and

would happen more frequently, were it not for the bursting of the eye, or the artificial opening of it. The sort of relaxation which follows, reduces the inflammation, just as a whitlow is relieved when the finger bursts, or is divided by a deep incision. When neither naturally or artificially relieved, the patient becomes comatose, and expires sometimes very suddenly. On dissection, you find matter within the ocular capsule, on both surfaces of the retina, and within the hyaloid.

The causes of ophthalmitis are first of all, injuries; such as, the operations for cataract, not extraction only, but sometimes even division through the cornea or the sclerótica; the excision of staphyloma; injuries received in blasting stone; and the like. Sometimes, in particular states of the constitution, very slight injuries, a mere prick, will give rise to phlegmonous ophthalmitis. A second cause about which we are perfectly sure, is the circulation of pus through the system, arising from the inflammation of a vein. The pus secreted by the sanguiferous membrane passes into the tide of the blood, and becoming arrested in some of the minute vessels of the eye, perhaps in the veins of the choroid, it there excites inflammation, and a new secretion of matter, which we find effused in the situations I have mentioned to you, after death. This is not, as it was once supposed, a mere deposition of the pus, carried in the circulation from the vein originally inflamed. It is a new secretion of pus altogether, from vessels excited to inflammation by the pus globules becoming arrested in them. The pus formed in the veins in cases of diffuse cellular inflammation, may, in this way, excite ophthalmitis. Some time ago, I was requested by a medical friend to visit a lady, who some days after her confinement was seized with headache, rigors, quick pulse, intense pain in one of her eyes, loss of vision of that eye, and swelling of the conjunctiva. She soon became comatose after I saw her, and died on the eleventh day after her confinement. I pronounced the case to be one of phlebitic ophthalmitis, probably originating in inflammation of the sinuses of the uterus. On dissection, we had made several incisions into the walls of the uterus, without discovering any diseased appearances. On examining, however, the place where the placenta had been attached, we found it covered with sanious purulent matter, and several of the veins proceeding from that place filled with pus.

It is a remarkable circumstance, that the symptoms in phlebitic and those in traumatic cases of ophthalmitis bear a strong resemblance to each other. The same pale chemosis of the conjunctiva, the same layer of lymph on the inner surface of the lower eyelid, the same excessive protrusion of the eye from the orbit, the same sloughing of the cornea!

Really, we could not tell, were we not informed by the history of the case, whether the ophthalmitis presented to our examination was traumatic or phlebitic. Does this arise from the pathological condition in the two cases being similar, inflammation in the veins of the eye in both, excited directly in the one and by the circulation of matter in the other? There is reason to believe that ophthalmitis follows as a sequela of fevers, both eruptive and others, such as measles, small-pox, scarlatina, and typhus. Now, in these cases, is the cause a circulation of pus, secreted perhaps in the veins of the abdominal viscera? These are queries, you see, which we cannot at present pretend to answer.

The treatment of ophthalmitis, whether traumatic or phlebitic, requires, in the first place, the free use of the lancet, cupping, and the application of leeches.

Tartar emetic in large doses has been recommended; a solution of six grains, say, in six ounces of water, and a table-spoonful of the solution to be given every half hour. But this I have not tried, as it would interfere with the free exhibition of mercury, which I consider to be more efficacious. The only case of ophthalmitis in which I have witnessed a perfect recovery was one in which I made the mouth speedily sore with calomel and opium. The aspect of the case was very bad, so that I considered it my duty to announce to the friends the dangerous situation of the patient; but as soon as the mercury told on the mouth, the ophthalmitis began to subside, the eyeball retreated into the orbit, and a perfect cure took place.

Counter-irritation to the feet, such as, by mustard-baths, or mustard-poultices, and counter-irritation to the nape of the neck by blisters, as well as blisters behind the ears, will be proper.

Pledgets, wrung out of cold water, and frequently changed, are the best local application in the early period of the disease; afterwards, a warm poultice.

Extract of belladonna may with propriety be smeared on the eyelids and eyebrow.

Should the patient become very weak in consequence of the pain and fever, and the debilitating influence of the treatment, mild nourishment must be afforded him, and you may give him quina. But in the early stage, you will, of course, recommend abstinence from food, and water only for drink.

The last point in the treatment refers to the evacuation of the serous fluid and pus collected within the ocular capsule, or deposited within the eye. I have, in several cases, punctured the eyeball in ophthalmitis, and thereby, I think, have saved the life of the patient. Sometimes I punctured the cornea, sometimes the sclerótica, and even when no pus, but only blood and watery

fluid were discharged, the discharge gave great relief by the relaxation it afforded to the compressed and distended eye.

The plan of opening the ocular capsule I first put in practice at the Eye Infirmary in February 1842. The eye, affected with ophthalmitis after an injury, was excessively hard, and greatly protruded, but around it I felt an obscure fluctuation, as if from fluid accumulated in the cavity of the ocular capsule, and this I determined I should attempt to evacuate. I went to work almost as if I had meant to operate for strabismus, dividing the conjunctiva in a vertical direction at the inner canthus, and towards the lower eyelid, and then directing the lancet backwards by the side of the eyeball, between the eyeball and the lower inner wall of the orbit, so as to avoid the rectus internus and rectus inferior. There was a sudden discharge of serous fluid, mixed with pus, and immediately the eyeball sunk back, and the cornea became quite flaccid, showing that the cause of the previous excessive hardness of the eye, and of its protrusion, had been not in the eye, but behind it. This, then, I should recommend to be done in all similar cases, and done early; not delayed till the eye is disorganized, or the patient sinking into the state of coma. The operation is simple, and easy of performance, and affords the most likely means of saving both the vision and the life of the patient. It is probable that opening the ocular capsule in the manner described may be of use in some other cases of protrusion of the eye—cases of exophthalmos altogether independent of inflammation, and where there is no reason to suspect the existence of any enlargement of the lachrymal gland, or of any solid or encysted tumor in the orbit, but merely a dropsy of the capsule; but to discuss this proposal at present would lead us away from the matter now in hand.

OBSERVATIONS

ON THE

NATURE AND TREATMENT OF THE MORE IMPORTANT DISEASES OF THE NERVOUS SYSTEM:

With Illustrative Cases.

By EDWARD BLACKMORE, M.D. Edinb.

Member Extraordinary of the Royal Medical
Society of Edinburgh, and Physician to
the Bath Penitentiary.

(For the *London Medical Gazette*.)

[Continued from page 574.]

CASE I.—A man, 32 years of age, was seized, after sleeping in a damp bed, on November 19, with pneumonic

symptoms, for which, in the next five days, he took only an emetic. On the sixth day of the illness he was bled to sixteen ounces; and on the ninth day, after a blister and free purging, he made no complaint but of headache, the pulse being at 80, and firm. In the course of the next six days little medicine was given, all the symptoms being relieved, excepting that the pulse remained as before. He then had a return of severe headache, attended with sleeplessness, vomiting, and a bleeding at the nose; the pulse still at 80, and stronger, on the eighth day from the first head complaint—a purgative now given. The following day headache severe; the face tumid; noise in the ears; the tongue white; the pulse as before.

Ten leeches on the head.

The day after, being the fifth of continued headache, he was seized in the middle of the night with apoplexy and palsy of the left arm; the pulse 112 just after the invasion. On the bowels acting he became sensible, and recovered the power of the arm; and in a few hours complained only of shivering and pain in the stomach; the pulse then 80, and firm.

A purgative of jalap, calomel, and senna.
Ten leeches to the head.

On the following day the symptoms were much relieved after a copious purging; but the day after, the 7th of more constant head complaint, the headache, noise in the ears, and swelling of the face, returned with severity; the pulse 72, very firm.

Bleeding to 20 ounces—the blood very sily and cupped.

The 8th day, the symptoms the same.

A purgative.

The next day, worse.

A blister behind the ears, and a purgative.

The 10th day, the same state. Pulse 96.

A purgative.

The 11th, a little relief, but the pulse 90, and full.

A purgative.

The 12th day, *i. e.* the 19th from the first head symptom, vertigo, and the bowels torpid.

Twelve leeches to the head, and a purgative.

In the evening, seized with stupor and convulsions, during which he was

bled to 22 ounces—the blood still very sily and cupped; the pulse after it 102; headache then relieved after leeching. The following day, delirium; pulse 90, and full; the bowels then purged, and he complained only of the hearing being acute.

Bleeding to 22 ounces—the blood as before.

Afterwards, a tendency to coma; pulse 96, sharp.

Leeches to the head.

The 14th day, delirium and costiveness.

A purgative.

In the evening, delirium continuing, and the respiration being stertorous, 20 ounces of blood were drawn from the temporal artery, which was sily. The next day, stupor, squint, and involuntary stools. Bleeding again from the artery to 14 ounces, which was followed by convulsions, and death in six hours.

Inspection.—Slight serous effusion under the arachnoid of the right hemisphere; a little also in the ventricles. The blood-vessels of the brain were not turgid; the spinal cord natural. Some effusion in the pericardium.

I saw this case in the practice of a gentleman now deceased.

If the early severity of the head symptoms, occurring after a pneumonic inflammation, had been adequately treated, had excited wholesome alarm, and if their remission had been regarded as deceptive while the pulse remained full and firm, and if the active bleeding in the latter stage had been adopted earlier, with more purgatives and mercury, might not the result have been different? The remarkable want of correspondence in the symptoms and morbid appearances is referrible to the treatment shortly before death.

CASE II.—A painter, aged 30, had complained for two years occasionally of severe headache, vertigo, and staggering, pain in the stomach, and sickness, particularly on taking even a small quantity of fermented or distilled liquors. He had had the colic from lead, but the bowels were generally regular.

On October 23d, 1838, he supped heartily on beef-steaks and porter, and the next morning had vomiting and

feelings of illness, but was able to pursue his work on that and the three following days. On the 27th, while painting the ceiling of a room, after a moderate dinner, he complained of his head, felt faint, staggered, begged to be taken into the air, and fell into profound apoplexy. He was bled largely an hour after the attack, after which he vomited. In two hours more I saw him, still in coma; the pulse 72, and small; the pupils dilated and fixed; and in another hour he died.

Inspection.—Much bloody ichor issued from the mouth; blood extravasated beneath the scalp at the vertex and occiput (which did not seem to have happened from a blow in falling). The cranium very thick, hard, and heavy, presenting on its inner surface many singular ridges of bone. The dura mater vascular, and adherent to the arachnoid; the lateral sinuses turgid with blood; the arachnoid thickened and opaque, with many minute deposits of calcareous matter on it at the base and vertex of the brain; a little serum beneath it. The pia mater very vascular; air and serum in its vessels; blood effused on it at the vertex, and near the medulla oblongata. The substance of the brain at the upper portions of the hemisphere was soft, and studded with bloody points; the lateral ventricles filled with clotted blood and serum; their walls much broken down and ulcerated, and from their floor a large cavity extended through the crura cerebri, and at the contiguous portion of the cerebellum, where it became a cell as large as a pigeon's egg, filled with blood; its boundaries also were softened, and apparently ulcerated. The large arteries at the base of the brain were dilated and flaccid.

CASE III.—A woman, 35 years old, who had suffered much from mental anxiety and poverty, had complained, in her pregnancy in October 1834, of symptoms of mild peritoneal inflammation, with dropsy of the legs, which were relieved by a small blood-letting. In the following January she had an easy labour, followed, however, by much nervous irritability and despondency of recovery. On the fifth day after delivery, she complained much of headache, which subsided after a purgative, and she appeared unusually

well the next three days; then, after severe mental disquiet, at 11 A.M. she felt benumbed at the left arm, which feeling quickly extended to the upper parts, and was followed by an apoplectic fit. She was seen in an hour by her accoucheur, when she had become sensible, and appeared only a little hysterical. She then took some medicine, which she vomited, and fell into a profound apoplexy. I saw her at 3 P.M., senseless, cold, and nearly pulseless; the arms drawn with tonic spasm; the right pupil dilated and fixed, the left moveable and contracted. After this, on using clysters, sinapisms, and evaporating lotions to the head, the pulse became distinct and regular, the respiration less noisy and more equal, and she could move the legs. The reaction increased, and the temporal arteries, particularly the right, throbbed strongly. She was then bled from both arteries to 15 ounces; the blood extremely dark.

Death followed in five hours.

Inspection.—The whole surface of the right hemisphere darkly stained, from blood extravasated beneath the arachnoid; the pia mater much engorged with blood. The whole substance of this hemisphere was extremely softened, broken down, and filled with clotted blood; the left hemisphere in a similar state, but in a slighter degree. The wall of the right lateral ventricle much softened; very little serum in the cavities; the remaining parts of the cerebrum and cerebellum were soft.

This softening of the brain had long preceded the apoplectic attack, yet it was shown by no symptom but nervousness and lowness of spirits, which seemed to be sufficiently accounted for by the domestic circumstances of the patient. It was connected with defective nutrition of the brain rather than with an inflammatory condition, and constituted a strong predisposition to this most fatal form of apoplexy.

CASE IV.—A sailor, aged 22, while doing duty in stormy weather, Nov. 10, 1819, was attacked with stupor and convulsions, which were followed by palsy of the right limbs, and indistinctness of speech. He remained in this palsied state to the 20th, when the convulsions returned, and he came under medical care and my observation. The symptoms, pain at the head, com-

plete palsy of the right arm, imperfect palsy of the right leg; his utterance very indistinct, and on attempting to speak the tongue was seen drawn to the right side, the mouth to the left; the pupils sluggish, the left eye protuberant; pulse 78, very full; the thermometer at 98° on the palsied side, at 101° on the sound side; the tongue white; bowels regular; mental powers apparently unimpaired. He had used no remedies.

Bleeding to 16 ounces—the blood natural. Purgatives.

The following day, a return of epileptic convulsions; pulse 60; the bowels costive in spite of the medicine.

The head shaven; 12 leeches, a blister, and purgatives.

The 13th day from the attack, a recurrence of stupor and convulsions, with stertorous breathing; pulse 52.

Bleeding from the temporal arteries to 36 ounces (6 only would flow from the left).

Shortly after which the pulse rose to 72, and the convulsions ceased; but the pulse again fell to 50, very full and firm in the left arm; the thermometer at 95° on the palsied side, 98° on the sound. The 14th day, breathing less stertorous; the tongue less affected; pulse 60, weaker; thermometer at 90° on each side. In a few hours, a return of the apoplectic state. Pulse 54, full and strong; animal heat 97°.

Bleeding again from the temporal artery to 20 ounces—the blood natural.

Shortly after which the pulse was 72, and still full. The 15th day, still apoplectic.

Leeches, and a purgative clyster.

Death the next morning.

Inspection.—In the left hemisphere of the brain, just above the ventricle, was an abscess holding an ounce and a half of pus. Inflammation in the brain seems to have existed at the time of the invasion of the epilepsy and hemiplegia, and to have passed into the suppurative state on the 11th day, when the convulsions recurred, or on the 13th, when decided apoplexy supervened.

CASE V.—This case, although not one of apoplexy, is placed here as showing in its symptoms a remarkable contrast to the foregoing, while the

morbid appearances are similar. A man, aged 21, after unusual confinement and exertion in his business as a tailor, was affected, June 8th, 1835, with severe pain in the temples, back, and limbs, with shivering and vomiting after his dinner. He had been troubled for a few days previously with pain and severe throbbing in the head, broken sleep, loss of appetite, and costiveness; which were relieved on taking physic.

Calomel with Colocynth, and saline antimonial medicines, were now given by his medical attendant.

The next day the symptoms the same.

Bleeding to ten ounces; from which he fainted; the blood very buffy and cupped; leeches to the temples; purgatives continued.

10th.—Most severe pain at the crown of the head.

Head shaven; a cooling lotion, leeches, and a bleeding to six ounces, which again induced syncope; the blood less inflamed.

11th.—Much better; pulse 70; bowels slow.

Purgatives; cold bathing of the head.

The next day, occasional pains at the head.

Cold affusion, salines with digitalis.

In a few days he was so much better as to go out of doors, and felt well, except that the pain in the head returned every night, when he had been in bed and asleep for an hour two.

In a few days, however, these paroxysms were relieved by cooling lotions to the head; and about June 20th, he made no complaint; the natural functions were good, but his manner was dull. On the 25th, the beginning of the fourth week of the illness, he was obliged to lie down in the afternoon, and was observed to stagger in walking, after it. On being questioned, he said that he felt well, except when rising from sleep, but the appetite had failed. The next day he complained of having had more pain in the head during the night; the pulse had fallen from 70 to 60, and was small; the tongue white; the face pale; eyes clear. He afterwards walked out of doors that day, and said he felt well in the open air.

27th.—Severe pain in the head, and slight vomiting in the night.

28th.—Vomiting after breakfast, then sleep, and a return of pain on awaking. He was able, however, to dine out; ate veal and drank porter; after which he again vomited, and the headache became intolerably severe. His medical attendant saw him in a few hours, and found the pulse weak and slow. An anodyne was given; and at 10 p.m. I saw him in the most excruciating agony at the temples; but the mental powers collected, the eyes and pulse natural, and he had no fever; his whole state exhibited the features of an attack of nervous headache succeeding to an inflammatory affection which had passed away.

A blister on the neck, tepid vinegar to the head, a stimulant foot-bath, and a slight cordial.

The pain continued unremitting until midnight, when he suddenly fell back in the bed and expired.

Inspection.—The skull very thick; the occiput vascular throughout its structure; the pia mater rather bloodless; in the upper part of the right hemisphere was an abscess containing an ounce of fetid green pus, its walls formed by coagulated lymph and indurated brain, forming a diseased mass the size of a hen's egg. The remainder of the encephalon was natural.

CASE VI. also is not one of apoplexy, but allied in its nature to a comatose affection, and marked by peculiar symptoms.

A man, aged 22, who had lived intemperately through the winter, contracted syphilis, and taken quack medicines, was affected at the end of April, 1830, with jaundice, which disappeared without medicine at the end of three weeks. In ten days more he had vomiting and severe pain in the head, with occasional fits of stupor, and a presentiment that he should die soon. These symptoms persisted for a week without disabling him for his labour, and on June 4th, 1830, he came under medical care, for the severe vomiting and costiveness.

Ordered—ten grains of calomel.

On the 5th the pulse was only 46! the vomiting had ceased on taking the calomel, but the costiveness was not overcome.

The head shaven, the calomel repeated, and purgatives.

The following day, much pain at the temples, occasional stupor, the pulse still 46; the bowels freely purged.

Cold to the head, cupping-glasses to the neck, small doses of calomel, and the purgatives continued.

The symptoms not being relieved in a few hours, he was bled to 10 ounces, after which he lay without speaking, tossing the head from side to side, and in two hours more he died unexpectedly.

CASE VII.—*An instance of encysted abscess in the brain; with an extraordinary remission of the symptoms.*

A boy, about nine years of age, had a blow on the left temple with a nail, at the beginning of August 1830, which was followed in the course of eight days by occasional vomiting and slight stupor. On the 11th he still complained slightly of his head, but was able to walk some distance to my house: no severe symptoms showed themselves; the scalp over the injured part was slightly swollen.

Leeches, poultices, and purgatives.

In a week he came to me again, with the symptoms much relieved, but some pus was flowing from the wound; he was referred to a surgeon for further examination, and in three days was reported to be going on well. On the 20th, however, he had an epileptic fit. It was then feared that suppuration had taken place in the dura mater, as for the last few days he had been delirious and restless at nights. The next day it was found that the temporal bone had been perforated; but throughout the succeeding days, to the 28th, he seemed much better; on this day his manner was stupid, and he had ear-ache, and a quick pulse, and was become emaciated; on pressing the temple much, pus flowed out, evidently from beneath the skull, for a probe could be deeply introduced without any obstacle.

Milk diet; Calomel and Rhubarb.

30th. — Much purulent discharge, sweats, and a rapid pulse, without any other bad symptoms.

Sulphuric acid and infusion of rhubarb.

September 4th. — He was down stairs, not complaining of the head; good pus flowing from the temple; the natural functions good; but the pulse

120. A fortnight afterwards I met him in the street, improved in strength and flesh, and without any morbid symptoms but a quick pulse, and the purulent discharge!

October 6th. — A return of pain at the wounded temple, a rambling gait, and a pallid countenance.

9th. — An improved countenance; little complaint made; some fungus at the wound, which the surgeon touched with blue stone.

13th. — The discharge had ceased, he grew sick and vomited in the night, and complained of the head. The next day these symptoms were more urgent, with a tendency to stupor; the eyes dull; the pupils dilated; the bowels costive; yet there was little of fever.

The temporal region shaven, leeches and poulticed; calomel, scammony, and salts, in repeated doses.

15th. — More pain of the head, fever, and stupor; all the medicines vomited; costiveness remaining; pulse 100, full.

Leeches and the purgatives repeated; general bleeding attempted in vain.

At a consultation it was determined to incise the scalp and lay bare the temporal bone: on doing which, a hole was seen in it just above the ear, and the probe passed inwards to the depth of an inch and a half, but no pus came out. The divided vessels were allowed to bleed very freely. The next day all the symptoms were wonderfully improved.

Purgative clysters.

17th. — The sleep good; the bowels freely purged.

20th. — More headache.

Ten leeches; purgatives and Colchicum.

21st. — A sleepless night, succeeded by vomiting and more pain in the head.

22d. — Some stupor; a look of prostration; vital functions low; the left pupil much dilated and fixed. Life was protracted to the 26th, when the left eye was observed to be excessively prominent, its pupil as before; the arms were drawn with spasm, and death soon followed; at the end of three months from the injury, and a fortnight from the severe relapse.

Inspection. — The prominence of the eye-ball gone. The interior of the left temporal bone, near the perforation, rough, and denuded; the dura-mater

beneath the parietal bone adherent to the pia-mater, which was very vascular; bloody points throughout the hemispheres; the posterior lobe of the left hemisphere at its upper part extremely softened, and between this portion and the ventricle was an immense cyst containing three ounces of green pus,—the walls of the cyst very vascular; three ounces of serum in the right ventricle. The pia-mater of the spinal chord also was vascular.

CASE VIII.—A fine boy, seven years of age, some members of whose family had died of hydrocephalus and mesenteric disease, after wetting his feet in the beginning of September 1822, complained of acute pain and tenderness in the region of the lower dorsal vertebræ shooting round to the navel. The pain came on with remittent fever at regular quotidian noon-day periods; the bowels were very costive. He came under my care three days after the attack. The symptoms were instantly relieved on applying eight leeches to the spine, and giving calomel and castor oil: but in a few days he felt a transient numbness of the lower limbs, while sitting up. On the 13th, he got pain in the bowels and diarrhœa, and the sense of "sleepiness" in the legs continued. By October 7th, he was unable to sit up without pain in the back, and the abdomen was tumid. In January 1823, weak health remained; irritation in the bowels the leading symptom; which was relieved by a blister, the blue pill, and aperients. In a year from the attack, a posterior projection of the dorsal vertebræ was very conspicuous, attended with pain in the loins and legs, inability of stooping, swelled feet, tumidity of the belly, and hectic sweats. Issues, rest, and mineral acids, were then employed. At the end of November he shewed symptoms of irritation in the brain, with pain in the stomach and a furred tongue. The mineral acids were discontinued, being thought to disagree, and alteratives were substituted. During the next twelve months the spinal disease was tranquil. In December 1824, he had scarlatina-anginosa, and varicella which matured during the course of the former disease. In the next two years and half the curvature of the spine was unchanged, the abdomen was very prominent, and he suffered from pa-

roxysms of severe pain and cramp in the legs, which confined him to the couch for weeks together, but at other times he could walk about. At one time in this period he had cough and hectic, which threatened to end in phthisis.

On May 3rd, 1827, he was attacked with a severe return of pain and cramp in the legs, which was succeeded by vomiting, costiveness, and acute pain in the head. These symptoms persisted for four days, when the vomiting ceased, but the pain in the forehead, with fever, gradually increased; the bowels being very costive. On the 8th, I saw him, in great suffering in the head, and in the back at the seat of the curvature, with fever, delirium, and tremors; the pulse 60, unequal and intermittent, yet full. He was bled to five ounces; after which the pulse improved; but in another hour, while conversing cheerfully, he fell into convulsions and coma, with stertorous breathing; and the pulse became very weak. On the next day, the coma continued, the pupils were fixed, the limbs affected with severe spasms, but he sneezed and coughed! The spasms ceased on applying an opiate cataplasm to the pit of the stomach; and death ensued in a few hours.

Inspection.—The membranes at the vertex of the head were very vascular; an ounce and half of serum was effused beneath the dura mater: the arachnoid opaque. The hemispheres of the brain very large, soft, and vascular. The pia mater in the ventricles very vascular; the cerebellum soft and vascular. An extreme curvature of the dorsal vertebræ, and of the angles of the ribs; the front portions of the bodies of those vertebræ were completely carious, forming large loose sequestra; the spinal cord here was extremely wasted, its fibres so distinct as to resemble a skein of thread; presenting a singular specimen of ulcerative absorption of the chord.

CASE IX.—A female, aged 20, had been affected with severe epilepsy from the age of 9 years, with habitual paroxysms of headache and excitement of the pulse; and the thyroid gland was enormously enlarged. Every sort of treatment had been tried,—bleeding in all its forms, setons, mercury, shaving the head, cold affusion, nitrate of bismuth and of silver, arsenic: and air

and exercise;—and all in vain. Relief was obtained only from purgatives. In the beginning of 1834, the fits became more severe, and were attended by deeper stupor; and in February of that year, after having been under my care fourteen months, she died in apoplexy.

Inspection.—The skull large; its ossification very irregular, being in one part extremely thick and dense, in another thin; the interior rugged with osseous projections; the crista galli particularly large. The membranes very vascular and opaque: two ounces of serum in the ventricles; the brain soft; the cerebellum and medulla oblongata and optic nerves particularly so. The arteries of the brain much enlarged.

CASE X.—A fine boy, 5 years of age, was affected throughout October 1824, with severe costiveness and urgent vomiting of all his food, and of a yellow mucus,—yet the appetite was unimpaired! He had also at the onset a slight pain in the belly, and feverishness. On the 31st, the abdomen was still tender, with obstinate costiveness for six days; thirst and a furred tongue, but no heat of the skin; pulse 103: no complaint of the head, sleep calm.

Leeches on the belly, calomel with antimony, and effervescing salines.

Nov. 2d —Epigastric pain relieved; one stool from a clyster; vomiting as before.

Warm bath; abstinence; leeches repeated, one grain of opium, and a purgative clyster.

On the 3d, two large stools; still urgent vomiting, tongue loaded, and thirst.

Leeches and clysters.

5th.—Still vomiting, excited even by eating a bismit: purged of unhealthy stools by the clyster. On the 5th, symptoms better, still slight pain in the abdomen, and a dysenteric stool; mouth sore from calomel.

A blister on the belly, clysters, salines, with digitalis.

11th.—A return of vomiting and costiveness.

Clysters and a warm bath.

13th.—Still vomiting; pulse 16; a scybalous stool.

Medicines as before.

15th.—An emetic of ipecacuanha given, after which, and a clyster, a natural stool passed, and he said he felt well. This remission continued to the 20th; then appeared a return of vomiting and costiveness; pulse 100 sharp.

Leeches and clysters.

22d.—The same state.

Bleeding to 2 ounces; other remedies as before.

23d.—Much relief; the blood natural.

Purgatives and clysters repeated.

28th.—A copious natural stool, after which the appetite was good. On the 29th, a return of pain and vomiting, with diarrhoea.

Bleeding to 2½ ounces; the blood much inflamed; salines, with digitalis.

Dec. 1st.—Sleeplessness, and then some stupor; pulse 90. The 2d, pupils dilated, tonic spasms of the limbs, pulse 70, irregular; a scybalous stool from clysters.

Sinapisms and cordials.

Death in two days more, after nine weeks of illness.

Inspection.—The transverse colon much dilated, containing faeces in one cell; the descending colon and the rectum very small: inflammation in the mucous coat of the caput coli, and faeces lodged there. The small intestines generally empty, and their mucous coat healthy; but a diffused vascularity on the peritoneal coat of the ileum, and a slight intussusception near its valve. In the head, the dura mater vascular and adherent, the lateral sinuses turgid with blood; the arachnoid very distinct, serum beneath it and in the ventricle. At the interior anterior part of the cerebellum, a hard tubercle, the size of a nutmeg; no morbid vascularity near it, but the other part of the cerebellum was very vascular and softened.

[To be continued.]

THE EMPLOYMENT OF MESMERISM
DURING SURGICAL OPERATIONS.*To the Editor of the Medical Gazette.*

SIR,

I THINK the writers of the letters which have appeared in the GAZETTE, in answer to a communication of mine upon the above subject, do not seem always to have borne in mind the object I had in view in addressing you. It certainly was not that of advocating the various extraordinary pretensions of mesmerism, of which I know nothing, and believe almost as little; but of pointing out that one of its pretensions, which does not outrage all possibility of belief, and whose existence has been testified to by some competent and trustworthy witnesses, and which, if real, is susceptible of such immensely beneficial application, has never been tested by a class of the profession possessing full opportunities of examining it, and whose verdict would be considered satisfactory and final both by the profession and public.

The possibility of the production of the mesmeric sleep is all but generally admitted, and the question at issue is simply, whether insensibility to pain is always, usually, frequently, or ever, a concomitant of that condition. How the admission of the possibility of this should involve the recognition of the possibility of clairvoyance, &c. &c. I cannot understand. The instances which have been cited in your pages, and which were adduced during the discussion at the Medico-Chirurgical Society (similar examples of which I, in common with all who have frequently witnessed surgical operations, have seen), of persons possessed of the power of restraining all expression of suffering during operations, have nothing to do with the question at issue, unless it is intended to explain all the instances adduced as examples of collusion, which the respectability of several of the narrators forbids. The simple question is, whether the temporary annihilation of sensibility during the mesmeric sleep is so complete as to render the pain of an operation unfelt. The analogies derived from the observation of a suspension of consciousness to as great a degree as this, in many conditions of the economy, at least prove the possibility of this, and make

out a case for inquiry. This pretension of mesmerism, too, beyond all others, admits of being submitted to examination, under circumstances when the exactitude of the results can be rigorously investigated, and all collusion or deception easily guarded against. I do not think those act wisely who attempt to settle the matter by ridicule and jesting. The subject is a grave one, and I believe a heavy responsibility rests upon those who refuse it consideration.—I am, sir,

Your obedient servant,

JOHN CHATTO.

Great Coram Street, Jan. 25, 1844.

POISONOUS EFFECTS OF THE
CYANIDES.

NO. II.—BICYANIDE OF MERCURY.

To the Editor of the Medical Gazette.

SIR,

IN a former communication which you did me the honour of publishing in the GAZETTE of Jan. 17, I gave an account of the exceedingly quick and powerful action of cyanide of potassium; and from subsequent experiments I have found that it is constantly decomposed, and evolves the odour of prussic acid, when it is mixed with the contents of the stomach, or even with weak acid liquors, such as porter, &c.

Following out my inquiries into the other combinations with this radical, I have found that the bicyanide of mercury exhibits peculiarities in its effects which are perhaps worth recording; and to prevent the unnecessary detail which would result from the description of every experiment I have made with this salt, I shall merely relate its action in two cases; they will be sufficiently expressive of all the rest.

Exp. I.—Five grains of bicyanide of mercury were dissolved in two drachms of water, and given to a small terrier dog, which had been fed about two hours previous. After the lapse of three minutes it began to retch violently, and threw up the half-digested remains of its food; these smelt distinctly of prussic acid, and created that peculiar bitter sensation in the throat which is so characteristic of the poison. In the course of the next ten minutes the convulsive action of the diaphragm and abdominal muscles was most distressing; it vomited again and again,

bringing up at each effort a small quantity of thick mucus. Other effects of the poison were manifested in its confused appearance, the giddy staggering walk, as if the voluntary muscles were partially paralysed, and in its laborious sighing respiration. In about half an hour it became calmer, and then lay, as it were, exhausted, making every now and then an effort to vomit. So it continued for two hours, when it began to recover; and the next day it had got so much better, that it was able to run about and feed well; its evacuations, however, continued for two days to be copious, and tinged with blood.

Upon testing the vomited matters, ample evidence was obtained of the presence of prussic acid, by its odour; and of the existence of cyanogen, by its appropriate reactions. Mercury also could be readily detected by means of the galvanic test.

Exp. 2.—Two grains of bicyanide of mercury were dissolved in a drachm of water, and given to a small terrier puppy, about two months old; it had not been fed for six hours. In two minutes, while the animal was playing with another dog which was present, it began to stagger, and lose control over the hind legs; it did not appear, however, to be in any pain, for it made great efforts to play with its comrade; it then staggered forward, and in its efforts to progress fell repeatedly upon the nose. In four minutes the spasmodic action of the diaphragm had commenced, and it vomited a quantity of thick mucus, having a faint odour of prussic acid. It now lay as if the limbs were perfectly paralysed. The mental faculties were not affected, for it followed with its eyes the movements of the other dog. In five minutes after exhibiting the poison, the characteristic symptoms of prussic acid commenced; it was then violently convulsed, gave a loud scream, the limbs becoming spasmodically extended, and the head drawn back. From this moment the respiration became laborious; and although it appeared partially to recover, yet it soon went off again into convulsions, uttering loud cries. It then lay, as it were, exhausted. The breathing became gradually slower and slower, and the heart's action fluttering and irregular. After the lapse of twenty-three minutes, it was found

that reflex action had ceased; the eye could be touched without winking, and the respirations had diminished to six times in the minute; these gradually became less and less frequent, and in one hour after the exhibition of the poison the animal died without the least struggle.

On making a post-mortem examination, the stomach was found highly congested, as indeed it is with most of the cyanides—it smelt of prussic acid, but chemical reagents were not sufficient to recognise the cyanogen: mercury, however, could be detected by the galvanic test. The vessels of the brain were full of black blood, the right side of the heart and cava full, and the lungs slightly congested.

When bicyanide of mercury is injected either into the veins or the peritoneum it produces all the above symptoms, with the exception of the violent vomiting.

In one instance, when two grains of salt had been injected into the jugular vein, and the animal had fallen with the effects of hydrocyanic acid, artificial respiration was resorted to, and in twenty minutes it had so far recovered that it could breathe of itself. In this way it was kept alive for upwards of an hour, when it fell into that peculiar exhausted state with its breathing becoming slower and slower until it died.

REMARKS.—It appears from these experiments that two grains of bicyanide of mercury are sufficient to cause the death of small dogs; that it acts, when put into the stomach, as a powerful local irritant, occasioning violent vomiting, and subsequently purging and bloody evacuation. The constitutional effects are first a loss of volition; the animal totters, and loses control over the limbs as if they were paralysed. The mental faculties, however, are not impaired, nor does there appear at this stage to be either pain or spasm. The second effect is like that of prussic acid, violent convulsions, loud screams, and a spasm of the respiratory muscles; from this time reflex action ceases, and the subsequent effects are paralysis of the voluntary, and afterwards the involuntary muscles, coma, the breathing becoming slower and slower, and the heart's action fluttering, and subsequently laboured. It at first appeared that these effects were rather due to a

gradual liberation of hydrocyanic acid, which maintained a slow but constant action upon the system; but the fact that the same symptoms are produced when the salt is injected into the veins or peritoneum, leads to a belief that the effects are specifically those of the combined elements. These experiments also show that prussic acid is liberated from bicyanide of mercury when it mixes with the acid contents of the stomach, and secondly, that both it and the mercury are easily detected.

When the poison is given in a large dose, as in the first experiment, the irritating property of the bicyanide serves as its remedy, for it produces such constant and violent vomiting that it is entirely expelled.

Lastly, the post-mortem appearances reveal a highly congested state of the stomach, a semi-coagulated black blood, which fills the right side of the heart and cavæ, and a congested state of the vessels of the brain.—I remain, sir,

Yours respectfully,

H. LETHBY, M.B.

Lecturer on Chemistry at the Medical School of the London Hospital.

12, Tredegar Square, Feb. 4, 1845.

ORGANIZATION AND PROTECTION OF THE MEDICAL PROFESSION.

THE QUARTERLY REVIEW, &c.

To the Editor of the Medical Gazette.

SIR,

THE Bill "For the better Regulation of Medical Practice," &c. introduced into the House of Commons in August last, by Sir James Graham, has now been fully considered and discussed. Some of its provisions have been highly approved, others have been condemned. Whatever difference of opinion may exist as to the number and nature of the latter, there are two leading points in which the Bill is almost universally pronounced to be defective. 1. Its comparative disregard of the interests and future position of the general practitioner. 2. The removal of restrictions on medical practice. The general practitioner observes, that while the Bill takes great pains to incorporate physicians and surgeons (the College of Surgeons having also recently received a new charter, and the College of Physicians being on the eve of receiving one) no such care is manifested

on his behalf. He sees, moreover, that a Council is to be placed at the head of medical affairs, in which both the Colleges are to be represented, while the class to which he belongs is passed over in silence, although the Council is to have entire control over the profession, even to the settling of what are to be considered public medical institutions, and the classes of persons who are to fill them. In addition to all this, he learns, with dismay, that the protection afforded him hitherto by the Apothecaries' Act of 1815, meagre though it be, is to be withdrawn. No wonder that he should be dissatisfied, or that he should endeavour to find out means of procuring for himself that consideration which the Bill denies him. Amongst these means, we find it proposed that the general practitioners should be separately incorporated in a Royal College of Medicine and Surgery. This is a natural and not unreasonable proposition: it is one, nevertheless, the expediency of which should be carefully weighed, and I trust that if there be among the general practitioners those who would "take time to consider," and who are unprepared to give the scheme an immediate and unconditional assent, they may not be regarded as less zealous for the well-being of their "order," than are those who have within the last few weeks, taken a prominent part in advocating the establishment of a third College. It has been too much the custom to think and speak of physicians, surgeons, and general practitioners, as if they were members of different classes of society, rather than of one and the same profession, and differing only in the extent to which they pursue its various branches and departments. This is an unsatisfactory state of affairs, and should, if possible, be avoided. In any attempt to re-organize the profession, it should be our aim to unite, not to divide, the qualified practitioners of the healing art; and without at all interfering with classifications and distinctions, which have been sanctioned by time, usage, and public convenience, this object may, I conceive, be accomplished, and through the instrumentality of institutions already established. To this end, the whole profession might be regarded as one great national institution made up of two constituent parts—medicine and sur-

gery, the former represented by the College of Physicians, the latter by the College of Surgeons; these bodies, in other words, forming divisions or departments of a National College or Institution of Medicine and Surgery. Coincident with this, an Examining Board should be appointed which should be common to the whole profession, and before which every candidate for a "license to practise" should be required to present himself—irrespective of the particular line of practice he might subsequently adopt, or of any degree or title he might be desirous to assume. The license, granted after successful examination, should authorize its possessor to act as a legally qualified and registered practitioner in any part of the British dominions. The Licentiate of Medicine and Surgery should be entitled to make application to have his name enrolled—on payment of a moderate fee, but without further examination—as an Associate or Member of the joint Colleges of Physicians and Surgeons*, *i. e.* of the National Institution of Medicine and Surgery—by what name soever it might be called. Associates or members should not, however, be admitted *de jure*, but elected by ballot; a preference being given to election, as affording, in some degree, a barrier against the introduction of improper parties.

Graduates in medicine, possessing the license to practise, should be admissible by election to the fellowship of the College of Physicians, provided their degrees were obtained under regulations which should have been sanctioned and confirmed by a general Medical Council. It should be one of the duties of the executive Council of the College to inquire into this matter, and to register parties admitted to the fellowship as legally authorised physicians of the United Kingdom. The College of Surgeons might also have an order of fellows, consisting of licentiates of a specified age, who should undergo a special examination in surgery. (Existing members of the College of Surgeons might be admitted to the fellowship on producing certain testimonials of character, professional

and moral, and after the expiration of a given term of years from the dates of their diplomas.) The degree of the Physician, and the fellowship of the College of Physicians, should be open, on examination, to members of the joint Colleges of a given age, who might not, from various causes, have qualified themselves, in the first instance, for this branch of the profession. Some such provision is made in clause 16 of Sir James Graham's Bill (the age of 40 years is surely later than necessary.) Physicians, surgeons, and general practitioners, would thus be huddled together as fellows or members of the same institutions*.

With respect to the government of the Colleges: they should each have a Council, elected by members of a certain standing, and by fellows conjointly. The Councils should consist entirely of fellows; and to this arrangement the members could hardly object; they would have an ample share in the election of the Councils, which would be responsible to them as well as to the fellows: the fellowship would be open to all: every fellow must have been a licentiate of medicine and surgery; many would also have been members of the Colleges; and with an independent Examining Board for licentiates, the authority of the Councils, so far as members were concerned, would be very limited.

In opposition to the foregoing suggestions, it may be alleged, that according to the plan therein proposed, the College in Pall Mall would be no longer a College of *Physicians*. My answer is: it would be as much, and more so, then, than it is at present, as it would comprise all the qualified physicians in England. What, at this moment, is the general practitioner? He is usually a member of the College of Surgeons; and whether so or not, he calls himself a surgeon, although, for once that he acts in that capacity, he acts a dozen times and more as a physician. Even the so-called pure

* Licentiates intending to become candidates for the fellowship of either College would not be compelled to enter the class of associates or members of the joint Colleges. There should, however, be a reciprocity between the fellows of one and those of the other, so far as related to their admission to libraries, museums, lectures, &c. They would all be attached to one national body, and on that account would be entitled to benefit by both the institutions of which that body was composed.

* For the sake of convenience, the Colleges are spoken of throughout this letter as separate institutions, although they would, agreeably with the plan suggested, form departments of one National Establishment, in the same way as two or more Colleges constitute a University.

surgeons have more medical than surgical practice. The College of Physicians is empowered by its charters to preside over surgery as well as medicine, and might, therefore, with great consistency, be made an element in the incorporation of a class of persons who, with a large proportion of medical, combine a comparatively small proportion of surgical practice. The general practitioners, if attached to one College only, would, for the reasons stated, be most appropriately placed in connection with the College of Physicians; but their practice partaking of both medicine and surgery (midwifery being a sort of neutral ground), they should be associated with each College, or (to express it otherwise) with each division of the bi-partite National College. It was a most unfortunate blunder in the above-named institutions ever to let them fall into the hands of the City Guild of Apothecaries.

Fellows of the Colleges might not like to associate with men who practise pharmacy. Those who should keep retail shops should not be recognized as members of either College. No law could perhaps prevent them from becoming shopkeepers; but, thus circumstanced, they should be satisfied to remain licentiates of medicine and surgery. If, after being admitted a member of the Colleges, any licentiate should open a shop, his name should be erased from the list, and he should be required to forego the privilege of membership. Becoming a tradesman for the sake of greater profit, he should be contented with a less amount of dignity. The preparation of his own prescriptions, and those of practitioners attending in consultation with him, is a custom which, for several reasons, the general practitioner could not suddenly relinquish; it is, however, one which is diminishing, and will be more and more abandoned, under the ever-increasing scientific attainments of the profession, the abolition of long apprenticeships, and of unqualified assistants—that wretched set of beings, who work for less than a menial's wages, and are too often found wandering the earth in a state of mendicancy.

The Colleges should have the power to expel both fellows and members who should be guilty of dishonourable conduct. This would afford one way of discountenancing and punishing the

grosser kinds of quackery within the profession.

If it were thought desirable, the fellows and members of the Colleges might, at intervals, have their separate meetings, for the consideration of matters appertaining to their peculiar interests; but the libraries, museums, lectures, and scientific meetings, should be open to all. Does any inconvenience or disadvantage arise from such an admixture of parties in the Royal Medico-Chirurgical Society? (Had such an arrangement prevailed in bygone years, the last-named body would never have been called into existence.) As provincial fellows and members would derive a less amount of benefit from the scientific establishments of the Colleges, their admission fees should be smaller than those of their metropolitan brethren.

At the head of the profession there should be a *Board of Control* or *GENERAL COUNCIL*, (the Council of Health and Medical Education of Sir James Graham). The *Representative* members* of this Council should be chosen in equal proportions by Fellows of the College of Physicians, Fellows of the College of Surgeons, and members of the joint Colleges, or I should rather say, by constituencies formed out of these several orders; universal suffrage would be quite unnecessary. Each class of practitioners would thus have an equal voice in the governing body of the profession. The various duties which would devolve on the General Council are specified in the Bill of Sir James Graham; amongst the most important relating to the profession would be the promotion of uniformity in the qualifications of all classes of practitioners throughout the United Kingdom, the visitation of Schools and Colleges, the superintendence of examining boards, registration of qualified persons, &c. &c.

The Board for the examination of candidates for the license to practise might be appointed by the General Council, the Colleges having the privilege of recommending persons proper for the office of Examiners. The latter should receive fixed salaries. The ex-

* I use the word "representative" to distinguish members of the Council elected by the profession from those who might be appointed by the crown.

amination fees might be paid to the Treasurer of the General Council.

I have treated the subjects of Incorporation and Examination with reference principally to English institutions. The same arrangements (slightly modified perhaps,) might be adopted in Scotland and Ireland. The Colleges of Physicians and Surgeons of Edinburgh, Glasgow, and Dublin, would, like those of London, be constituent parts of the National Institution. (Would the term University of Medicine be admissible?) Uniformity of qualification for degrees and licenses, if established through the medium of the General Council, should be attended by reciprocal privileges throughout the three countries. The physician, surgeon, or general practitioner, qualified in one, should be at liberty to pursue his vocation in either of the others.

In reference to the Councils of the Colleges and the representative members of the General Council, it may be said, that agreeably with the above plan, too large a number of persons would probably take part in their election. Little apprehension need be entertained on this point. I have ventured to suggest that the electors should constitute a part only of the profession, and of this part a large proportion would never vote. Men are often contented to have a privilege, without caring to exercise it. If we look around at the various literary and scientific societies scattered over the kingdom, we shall find that but an inconsiderable proportion of their members trouble themselves to vote in the election of officers, although residing within a limited circle. How many of the newly made Fellows of the College of Surgeons voted a few months ago in the election of the three additional members of the Council, although they then met for the first time, to use their recently acquired privilege? Not one-fourth. Voting papers might be given to those only who should express a wish to have them. The names of persons proposed should be given at the same time, and still further to prevent confusion, every candidate might be required to be nominated by a given number of electors.

A writer in the "Quarterly Review," (January 1845) informs the readers of that journal, that some of the speakers

at public meetings held to discuss the Bill of Sir J. Graham, are bent on having a sort of parliament, elected by 20,000 or 30,000 practitioners. The number of persons who advocate such a scheme must be very small; the bulk of the profession make no such demand, although there are few practitioners who do not think that the ruling bodies of the profession, should in some way, be made responsible to the members thereof; and this opinion is surely justified both by reason and experience. The little interest the corporations have displayed in the general welfare of the profession, or in anything but what has appeared to concern the favoured few, whom they have considered themselves at liberty to regard as the sole objects of their superintendence, affords a sufficient explanation of the demand for representative forms of government. The College of Physicians—a much reformed institution within the last few years—was originally endowed with extensive powers over the practice of medicine, surgery, and pharmacy.* It had, however, up to a recent period, so far departed from the intentions of its founders, as to become little more than a club for those metropolitan physicians who were fortunate enough to be Fellows of the College. The Licentiates were treated with indifference, if not with contempt, and as for other departments of the profession, they were quite beneath the notice of this very exclusive establishment. The College of Surgeons is declared by its Council to be a purely surgical institution. Its members are probably not fewer than 10,000. Of these not more than 200, if so many, practise as pure surgeons—or profess so to practise: some having nothing to do, and those who have employment, dabbling a little in physic in addition to their surgical business. In the year ending June 1844, the sum of £9,486 was paid to the Court of Examiners; it would be interesting to know how much of this came from the pockets of persons intending to confine themselves to the practice of surgery. The funds for the enlargement—I might almost say, the

* The censors have authority to visit and inspect the shops and *materia medica* of druggists. In the year 1811, a report was published by the College, wherein it was recommended that they should examine and license the chemists and druggists of England and Wales.

re-building of the College, the maintenance of the Hunterian museum, library, lectures, &c., the salaries of examiners, Council, and other officers and servants, have been and are derived almost entirely from its members, who have no control over an establishment, to whose splendour and importance they have so largely contributed. In the constitution of the Council of Health, as laid down in the Bill of Sir James Graham, the general practitioners discover a similar exclusion of their body. The Quarterly Reviewer observes, in reference to this subject, "The general practitioners will complain that no certain provision is made for them to be represented in the Council, although there are some points connected with their part of the profession which the Colleges of Physicians and Surgeons may not sufficiently understand; and we cannot but assent to the justice of this complaint." The Reviewer thinks it not improbable that parliament will settle this point by vesting in the Crown the entire appointment of the Council, the bill merely specifying of what classes of persons it shall be composed. Provided all classes be equally specified, this alteration would be an improvement on the Bill as it now stands. It is possible that the Crown might make a better selection than the profession itself, divided and conflicting as are now its component parts; but as a general principle this is hardly to be expected. Amid the fluctuations of political parties, and the changes of governments, it is not to be supposed that we shall have a succession of Home Secretaries who will be sufficiently conversant with medical affairs to form the most accurate judgment of the qualifications required by the members of a Medical Council. They would have to apply for information somewhere, and would not the members of such a Council be more likely to meet with the confidence of the public as well as of the profession, if their fitness were attested by a considerable body of their brethren, than if their appointments were made at the instigation of perhaps two or three private individuals whom the minister might consult, and who would be in nowise responsible for the advice they might tender? The sole object of the profession is to procure the most efficient

system of government within its reach. No human institutions are perfect; they are all more or less defective and liable to abuse. In looking back on the history of those connected with the medical profession, a great majority of its members have arrived at the conclusion that most of their defects and abuses have arisen from the circumstance of their executive councils not having been made sufficiently responsible for their acts.

Some such mode of organizing the profession as I have endeavoured to sketch would present many advantages, and would realize several objects which medical reformers have been, for a series of years, endeavouring to obtain. It would unite and consolidate the profession, preserve the unity of medicine and surgery, ensure uniformity of qualification, and provide a representative and responsible government both in the corporations and the supreme Council. It would secure to general practitioners, as well as to physicians and surgeons, all the benefits they could expect to derive from incorporation; for, after all, it is uniformity of qualification and protection that the profession is most in need of. It may be objected, that according to such a plan, the general practitioners would occupy an inferior position; but would a separate incorporation of their body alter the case in this respect? Constituted as the profession is in this country, would not the new College be regarded as third in rank as well as in date? The position of the general practitioners would be an honourable and respectable one, and if the physicians and surgeons were placed a little above them, they would be so placed on just and equitable grounds. They would all, in the first instance, be licentiates, many of them would be members of the joint Colleges, and they would hold the fellowship at a later age, and after an examination superadded to that required for the primary grade. There would be no invidious distinctions, no exclusiveness. The fellowship would be open to all who chose to aspire to it, and it is not improbable that in process of time a vast majority of practitioners would, sooner or later in life, become fellows of one or other College. There would, moreover, be no arbitrary limitations on practice; it would not follow that,

because the general practitioner should take a degree in medicine, he should resign the practice of surgery or of midwifery, if disposed to continue them, although etiquette, if not compulsion, should oblige him to relinquish all connection with pharmacy. Whatever advantages might attend the establishment of a third College, it can hardly be denied that such an institution would keep up and perpetuate divisions and separations of medical practitioners which have for years been productive of most unfavourable consequences. It could not, for a very long period at least, be expected to stand on a level with existing Colleges, in the records of which are to be found the names of so many illustrious individuals. Under the new and yet to be amended charters of those Colleges, many of the ablest general practitioners would be continually drafted into those institutions, and so far as the examination of general practitioners by men of their own grade is concerned (a point much insisted on) I would humbly submit that a board of examiners composed entirely of this class would be objectionable. If they should hereafter be incorporated with authority to examine candidates for their grade of the profession, the general practitioners would, I doubt not, find it expedient or necessary to have a mixed board like that which has been recommended for licentiates in medicine and surgery. These opinions, formed after much reflection, I submit with diffidence, and with no determination to adhere to them if further reflection should prove them to be untenable. They do not, in my own mind, constitute insuperable objections to a third College; on the contrary, I would say that if the Colleges of Physicians and Surgeons be unwilling to acquiesce in some arrangement whereby the general practitioners shall be associated with those institutions on conditions both honourable and advantageous to them as a body constituting the mass of the profession; if the Colleges prefer adhering to their present policy of alienating this important class; then I cannot see on what ground they can oppose, or should be allowed to prevent, the grant of a royal charter of incorporation for general practitioners. It would be neither just nor decent in

the Colleges to divide between themselves the examination-fees of general practitioners, if all connection between the two parties were to cease on the payment of those fees.

Respecting the second main defect of Sir James Graham's Bill—absence of protection—there is, save in the minds of a comparatively few persons, but one opinion throughout the length and breadth of the land, viz. that to remove restrictions on medical and surgical practice would be most dangerous to the public, and alike injurious to the welfare, respectability, and usefulness of the profession. Such is the language of every meeting that has been held to consider the bill—from Devonport to Newcastle, from Liverpool to Dover.

Unauthorised practice may be considered under two heads: 1. Quackery. 2. Irregular practice. The first species no man (not even my friend Dr. Cowan) expects to *annihilate* by Act of Parliament; but most men think it may be very materially diminished and controlled by legal intervention. According to the Quarterly Reviewer, the profession demands that "the whole race of quacks and unlicensed practitioners should be dealt with in a summary manner," and that "they will be contented with nothing short of this." The writer must be under a misapprehension, or he is unacquainted with the state of professional feeling, or has not had an opportunity of ascertaining correctly what has been going on throughout the profession during the last five months: at all, or nearly all, of the aforesaid meetings, as well as in the various written or printed critiques of the Bill, it has been acknowledged that quackery is not to be extinguished by any law, how stringent soever it might be; but surely such an admission forms no argument against an attempt to counteract its baneful effects. Laws and penalties have never proved, and probably never will prove, equal to the suppression of crimes and offences; but the legislature is not, on that account, absolved from the duty of protecting the public against them, so far as this can be accomplished by appropriate legal enactments. Quackery is a very sweeping and comprehensive term: it includes many absurdities which no law could recognize, and the interference with which would subject

the complainant to ridicule instead of redress. Those persons who have a taste for empiricism, who think "the pleasure is as great of being cheated as to cheat," would, even in the face of penalties, have abundant opportunity of gratifying their morbid inclinations. There will always be a large amount and many kinds of quackery, against which no law would ever be directed, although the dread that on some occasion or other the quack might be called to account would act as a powerful check on his proceedings, and would unquestionably prevent a great deal of the fraud, cruelty, and mischief, of which quackery is the parent. The quack would have to pursue his avocation in a much less ostentatious manner than he is now permitted to do, and if the publicity of his pretensions were curtailed, his main prop and dependence would be, in a corresponding ratio, taken from him. The Reviewer advances, among other reasons for letting quackery alone, that there is much of it within as well as without the ranks of those "who march under the banners of the true faith;" and he brings forward the instance of certain medical students (their number he hopes is not great), who, having for years neglected their studies, and spent their time in idleness or profligacy, are eventually prepared for their examinations by a three months' process of "grinding" or "craming." That such cases do occur, and not infrequently, no one at all conversant with the habits of medical students can deny: but does their occurrence constitute an argument against quackery? Few, I imagine, will think so, although many will be apt to consider it as forming a very powerful argument against, and condemnation of, the present system of medical education, and the manner in which the examining and licensing boards fulfil their duties. Why do they permit such persons to enter into practice stamped with their certificates of qualification? Why do they not devise some unequivocal method of ascertaining that candidates for their diplomas, &c. have actually studied their profession, and been repeatedly examined by their own teachers, before submitting themselves to that final ordeal which, if successfully passed, enables them to go forth to the world as duly accredited practitioners of medi-

cine and surgery. Reprehensible as are the preparation and examination spoken of by the Reviewer, the case would be still worse if the student were permitted to assume the function of the practitioner without either one or the other. Under a proper system of medical government and protection, such abominations would be no longer heard of. It is much to be lamented that medical men should ever seek to promote their success by unworthy means, or that they should at any time be found advocating so many of the fooleries and quackeries of the day. Their more honest brethren cannot too strongly discountenance such discreditable characters. The moral influence of the former may do much, but the Reviewer may feel assured, that internal quackery will be most thoroughly discouraged, and that honourable feelings and conduct will be most effectually promoted, by the adoption of such a system as shall induce well-educated men to enter the profession, and shall protect, as far as possible, those who are willing to incur the expense and anxiety of a sound and liberal medical education from being placed in unfair competition with men whose dishonesty and baseness are generally proportioned to their ignorance and want of refinement. The Reviewer fortifies himself with the opinions on quackery promulgated by the Colleges of Physicians and Surgeons of Edinburgh, and he moreover gives his readers the probable ground of those opinions, when he says, in regard to Scotland, "Quackery is comparatively unknown in this part of the United Kingdom."

There is not, we may readily conceive, the same scope for quackery in Scotland as there is in England. "Sawney" is a more cautious, discreet, meditative person, than his brother, "John Bull." He takes better care of himself and of his money, and has less of the latter to throw away—even in the luxury of being cheated. The gullibility of poor John is notorious. We must bear in mind, however, that Colleges do not always accurately represent the opinions of their individual members. To what extent this may be done by those in question, I cannot presume to say, but we find the Glasgow Medical Association taking quite an opposite view of the matter, and I am not aware that Scotch gentlemen prac-

tising south of the Tweed are less exposed to restraints on quackery than are their English brethren.

What may be termed irregular medical practice would be a practice under the control of a penal enactment than that species of impost to which the term quackery is usually applied. The irregular medical practitioner I would describe as the man who, with some degree of medical knowledge, but one licensed, and without a license, assumes the functions and external guise of the regular and fully qualified member of the profession. He is not exactly a quack, inasmuch as he professes to be guided in his practice by those principles which have been received and acted upon by the legitimate professors of the profession. It may be said, it would be difficult to give a legal definition of such persons, and that any clause of an Act of Parliament, framed with that intention, would be easily evaded. I do not think the author of a Medical Bill need trouble himself with an attempt to lay down with mathematical precision the line of demarcation between the true and the spurious practitioner. Let the law provide that any person who shall undertake, without a license, the treatment of diseases or bodily injuries or in any manner act in the capacity of a medical or surgical attendant on the sick, with a view to pecuniary gain, shall be subjected to fine or imprisonment on conviction before a bench of magistrates. The latter would have little difficulty in deciding who were, and who were not, acting as regularly qualified medical men. Parties dissatisfied with their decision should have a power of appeal to a superior court.

"Inferior druggists," says the Quarterly Reviewer, "excite the jealous of Medical Associations." If this assertion is to be understood as applying to the counter practice of those persons, the Associations will probably differ from the writer. Such practice cannot be prevented, and if it could, would the profession be benefitted by its transference to themselves? But under the proposed Bill druggists would not be limited to their counters; they would be at liberty to visit patients, to treat medical and surgical cases, and, I mistake not the meaning of clause 1, they might commence practice with

the title of "Doctor" appended to their names, and a German diploma placed within sight of their admiring customers. The Reviewer seems to think that the increased qualification of medical men must be attended with a corresponding increase in their charges. They are now perhaps as much employed by the working classes and the poor as they ever have been, and as for the Doctor's bill, it matters little, in the majority of cases, amongst these classes, whether it be large or small—it is never paid. So far as the medical man's interests are concerned, the druggists would be welcome to such practice. (The subject of an improved system of medical attendance on the labouring population is one of great importance, but into its details I must not enter more fully at the present moment.)

The irregular practitioner, far more than the quack, is the person whom the qualified man is interested in putting down. His pretensions, unlike those of quackery, are liable to be confounded with the hard-earned qualifications of the regular profession, and it might easily be shown, that the public welfare would suffer from the tolerance, or, in other words, the tacit recognition, of such a class. The true man would be continually driven out of the field by the pretender. He could not resort to the same unworthy means of procuring notoriety and worldly success as the latter would be almost sure to call to his aid. Whatever might be the result of a penal enactment (no fair trial of which has yet been made in this country), it would at least testify the desire of the legislature to preserve the health and lives of the people (who will ever be inadequate judges of medical and surgical skill), while its absence may create the belief that the sciences of medicine and surgery are so imperfect, their professors so little to be relied on, that Parliament has deemed it advisable to throw open the practice thereof to all who care to undertake their perils, or to share their profits.

The Reviewer thinks the corporations are often blamed for the discontent existing in the profession, and which should rather be referred to something in the society leading to an inordinate seeking of our ranks. This is a mistake. Many young students of medicine

idea of the emoluments of medical practice. They flatter themselves with the idea that it will secure to them a handsome and speedy livelihood, and that no great capital will be required at starting. Many fond parents are also "daft" enough to suppose that to put their sons into a *profession* is the right way to make them "gentlemen." The corporations are not, however, quite guiltless on this point. Uncontrolled and irresponsible, they have admitted many, many persons, to practise, who have been sadly deficient in professional attainments, and still more so in preliminary education, and who would have been more usefully and more happily placed in some other walk of life. The Quarterly Review, of Jan. 1841, admits that corporations, like individuals, are apt to become avaricious.

The Reviewer so often referred to declares that the profession are not agreed on what should constitute medical reform, except in one point, viz. "deliverance from quack competition." In making this statement he is clearly misinformed. The profession are agreed on many points; and more than this, there is amongst them a great degree of unanimity in relation to Sir James Graham's Bill. The *principles* on which that measure is based have been generally approved; its defects arise from the too limited extent to which those principles have been carried out: the principle of representation, for example, has been recognized in the Council of Health, so far as regards physicians and surgeons, but it has stopped short of the general practitioner. The principle of protection, so far as the *public* practice of the profession is concerned, is also observable, and if the same solicitude had been evinced towards other portions of the community, as the Bill has displayed on behalf of hospital patients, soldiers and sailors, prisoners and paupers, there would have been no room for complaint under the head of protection. Several provisions of the Bill have met with very general commendation. Let us, then, hope that Sir James Graham will reconsider those points on which there is a difference of opinion between himself and the majority of the profession, and so amend the Bill before bringing it again into the House of Commons, as to render it a measure of real and lasting utility to the public, and not in name only, but in deed, a "Bill for the better re-

gulation of Medical Practice throughout the United Kingdom."

I have the honour to be, sir,

Your obedient servant,

CHARLES T. CARTER,

Honorary Member (late Secretary) of the North of England Medical Association.

Adley, Middlesex, Jan. 29, 1845.

ANALYSES AND NOTICES OF BOOKS.

"l'auteur se tue à allonger ce que le lecteur s tue à abréger."—D'ALEMBERT.

Of the Nature and Treatment of some of the more important Diseases, Medical and Surgical, including the Principal Diseases of the Eye. By JOHN CHARLES HALL, M.D. of East Bedford. 2d Edition, enlarged.

In the work before us a variety of subjects are discussed, viz. diseases of the eye, fistula, fractures of the cranium, hsem, bronchocele, cancer, suppression of urine, uterine hæmorrhage, gout, and rheumatism. Many of the chapters, the author informs us, are founded on cases sent from time to time to the MEDICAL GAZETTE. The principal attention in the present volume consists in some additions to the section on diet and disorders of digestion, and the introduction of a chapter devoted to an examination of the utility of nitrate of silver as a local application in erysipelas, in which an endeavour has been made to collect the opinions of all writers of authority on the matter, as well as the hitherto unpublished results that have followed its employment in the practice of many distinguished surgeons.

The following hints are apposite in reference to dyspepsia:—

States of mind, and habits of body, such as mental trial, mental distress and solicitude, much study, want of exercise, exert a marked sway over the functions of the digestive organs; hence or task is the most difficult when the patient's anxiety relates to his own complaints; when the mind dwells only on his state of health, and he continually tells you his recovery is hopeless. If you say to him his ailments are imaginary, laughs in your face, deserts you, and places himself under the care of some abominable quack, who fleeces his pocket, and ruins his health, by the continued use of purgatives, the injurious effects of which I have already pointed out. We can obtain the confidence of such

a one, much is already gained; get him to "*travel in search of health*," for a time to forget his business—to forget himself; keep the mind ever engaged, and the eye ever resting upon some new scene: thus, six weeks spent among the mountains of Switzerland, or upon the rivers of Germany, or in travelling through any pleasant part of our lovely island, will often do more in bringing the dyspeptic hypochondriac to a state of health, than an eternity of physicing and dieting at home: 'you cannot minister to a mind diseased: throw physic to the dogs!'"

The author very properly condemns a constant and indiscriminate use of purgatives in the treatment of dyspeptics. He says, "The imagination of the sufferer solicits a temporary respite from pain by strong purgatives at the risk of future health and comfort. There is not a symptom of the disorder which is not rendered more severe by the evil practice of continued purging, either directly, by irritation of the alimentary canal, and disturbance of the natural course of its functions; or indirectly, by morbid influence on the mind of the patient, a result no less injurious than the former."

As an antacid, Dr. Hall approves the combination of bicarbonate of potash with nitre, as recommended by Dr. Prout, although he does not pretend to explain its *modus operandi*. He advises this remedy to be persevered in, until, with the assistance of proper medicines and diet, the disease is subdued, and the distressing secondary effects of acidity in the *primæ viæ* prevented; for alkaline remedies alone are useless in removing acidity, they only neutralize the acidity when formed, and if taken in too large doses, and at improper times, add to the disease by causing an absolute increase of acid. Bitters, he justly observes, are, like purgatives, resorted to far too much. We have, in our own practice, witnessed decided advantage in such cases from counteracting lactic fermentation by the aid of astringents; such as extract of uva ursi, gallic acid, and the like. These substances not only check this morbid disposition, but likewise impart tone to the stomach. When the acidity is confined to the large intestines, the author considers it useless to employ the soluble antacids, "they are rendered valueless long before they reach the seat of the affection — magnesia will therefore be found

more advantageous in such cases. The best and shortest plan, however, is the injection of a little warm soap and water, which at once removes the offending cause."—p. 229.

In the concluding chapter on the use of nitrate of silver in erysipelas, Dr. Hall verifies the old adage, *quot homines tot sententiæ*. Subjoined is the result of his own experience: "I have so often seen the nitrate of silver employed, and so often employed it myself with the most decided benefit, that I am at a loss to account for the fatal results that have followed its application in other hands. Eighteen months ago I attended a nobleman (in consultation with my esteemed friend, Dr. Schofield, of Doncaster,) who was suffering from a severe attack of erysipelas of the face; I applied the nitrate of silver freely; the result was highly satisfactory and the patient recovered; so did three other similar cases within a month of the same period, and both before and since I have used it, *not certainly with the same success as Mr. Higginbottom*, but it has never in my hands done harm, and has proved quite as successful as any other remedy with which I am acquainted. *Now it must be distinctly understood that lunar-caustic does not repel erysipelas*, but by its application the violence of the disease is moderated and localized; it must also be remembered that the local affection, whatever part of the body it may attack, becomes a secondary cause of disease, and undoubtedly keeps up the original constitutional disturbance, in exact proportion to the extent and severity of the local disease; it appears then clear that it is of the greatest importance, not only to endeavour to correct the errors in the system, but also to limit the local disease."

MEDICAL GAZETTE.

Friday, February 7, 1845.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

MEANS OF PROTECTION.

WHILE going to press last week, we were favoured with a note from the Provisional Committee of the Association of General Practitioners, intimating

that a copy of certain communications with the Home Office would be open for our inspection. It appears that a memorial had been addressed to Sir James Graham, with the view of inducing that Minister to advise Her Majesty to incorporate the general practitioners by "charter into an independent college, with a governing council and power to frame by-laws, and provide for the future education of the general practitioner, and to place them, as respects the management of their own affairs, in every respect on a footing of equality with the existing Colleges of Physicians and Surgeons."

Sir James Graham, falling back upon his recent correspondence with the Master of the Society of Apothecaries, plainly informs the memorialists, that they have not sufficiently complied with the conditions laid down for their guidance in an affair of such importance.

"The names appended to it, although of great respectability and deserving of high consideration, belong exclusively to metropolitan practitioners, and the subscribers do not profess to have any authority to represent the wishes of their provincial brethren. The memorial neither explains the proposed organization of the intended corporation, nor furnishes the names of those to whom the charter is to be granted, who, as is usual in such cases, would be named as the first office-bearers in the corporation."

The Secretary of the Home Department cannot fail to notice that numerous petitions have been forwarded to Parliament by highly respectable bodies of the profession throughout the provinces, praying for alterations and amendments in the the proposed Bill, without the most distant allusion to the scheme of incorporation. The grand move has been chiefly confined

to London and the suburbs. He therefore very judiciously tells the memorialists, if you can "satisfy me that the expressed wish of your association is felt also by a large number of country practitioners, I shall examine the draught of your proposed charter with every disposition to promote the usefulness and respectability of the important branch of the profession to which you belong."

No Minister of State could have penned a more fitting letter for the occasion.

We have all along considered the project as one of a most questionable nature, so far as the present interests and future prospects of the general practitioners are concerned. On no other ground would we urge against it the slightest shadow of objection. We believe that, so far from being aggrandized, they would eventually be lowered by this much-coveted boon. They would take rank as a third estate, and be viewed pretty much in the same light as the *officiers de santé* are in France; and as no one branch can suffer without the others being reciprocally affected, the sequel would be a debasement of the whole mass. The measure, moreover, is intrinsically schismatic, and consequently calculated rather to augment than abate the discontent and dissension which unhappily have so long divided the body medical. Physic, as an art, is one; why, then, should such divers denominations be formed and perpetuated?

The general practitioners lay evident stress upon the circumstance, that their class has been created "by the customs and necessities of the community;" but have not the throng of chemists and druggists been likewise created by the customs and necessities of the community? The argument thus cuts both ways.

The main principle, never to be lost sight of by the legislature, is the pro-

tection of the public. That should on no account be entrusted to any corporation having power without virtual responsibility, as heretofore the case. We therefore repeat, what we formerly inculcated, that the most salutary course would be insured by means of a clause, enacting that all men henceforth to receive any license whatsoever to practise in the healing art, should first prove, before competent tribunals, to be appointed for each of the three kingdoms, and by proper and adequate tests, their possessing a certain standard of medical and other knowledge; and that all holders of any professional title thus conferred, should enjoy in each of the three kingdoms all privileges and immunities as qualified practitioners. Let the examiners be quite independent of all existing corporations, and have no other object but the selection of fit men as guardians of the public health. Let a general registry of all licensed practitioners be enforced annually, at a uniform moderate fee, and let wilful omission of such registry be visited by certain pains and penalties: say suspension or withdrawal of the license. Let all persons simulating a medical title or grade which does not belong to them, or convicted of practising without certificate, be made liable to summary punishment, the power in such case to be exercised by a magistrate or by two magistrates. It is universally admitted that the law as it now stands has signally failed of attaining the contemplated end. Indeed, the right of prosecuting has been a great disadvantage to, and thrown much obloquy upon, the Society of Apothecaries; because it has been wielded on selfish grounds, and wholly irrespective of the public interests, to coerce not gross incompetence, but technical disqualification. Let medical men be entitled by law to receive fees for their visits, and charge a mere equivalent for what medicines they may

require to furnish in rural districts. We object to any contumelious distinction into persons charging only for the exercise of their skill, and into those who should make a trade of practice by charging for the drugs they send in. There is no chance of melioration until the practice of medicine and surgery is kept totally separate from that of pharmacy.

It is high time for apprenticeships to be abolished. The thralldom and mispent time incidental to such a system must inevitably tend to exert a demoralizing influence upon youth. By lessening, moreover, the expense of education, it merely tends to increase the multitude of young men annually flocking into a profession which is both overstocked and impoverished. Each individual underbidding his neighbour, doomed perchance to eke out a miserable livelihood by petty traffic in drugs, of which he knows little more than the external characters. The institution of long apprenticeships, says Adam Smith, has no tendency to form young people to industry. "An apprentice is likely to be idle, and almost always is so, because he has no immediate interest to be otherwise*." Why, indeed, should a public law, meant exclusively for trades carried on in market towns, by the 5th of Elizabeth, and commonly called the Statute of Apprenticeship, have ever been foisted upon a liberal art? We can recognize no other motive save that of pecuniary gain—the receipt of a fee, and the prospect of engaging the services of an assistant at a cheap rate. We maintain, that in the course of a very few months, any lad of moderate capacity may master the necessary manipulations, which he is now compelled to dawdle over during five of the most precious years of his life.

We are glad to perceive that Sir James

* Wealth of Nations, Book I. Chap. 10.

Graham is to bring forward his motion for leave to bring in the Bill, on Tuesday week. It is the intention of the Rt. Hon. Baronet to propose some alterations in the measure of last year. These are to be duly stated, together with the grounds on which they are based, at the time above specified. From what we hear, there is a strong feeling on both sides of the House in favour of an amended Bill. We are led to anticipate that the enlightened statesman, who has been at so much pains to investigate the matter, will introduce such modifications as shall satisfy every reasonable member of the profession.

In conclusion, we invite the attention of our readers to an elaborate paper in the present number of the *GAZETTE*, by Mr. Carter, in which certain views we have been advocating are very clearly put.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Tuesday, January 28th, 1845.

MR. STANLEY, President, in the Chair.

Brief Notices of the Variolous Epidemic of 1844. By GEORGE GREGORY, M.D. Physician to the Small-pox and Vaccination Hospital.

AFTER noticing the remarkable freedom from small-pox which the metropolis enjoyed during the years 1842 and 1843, the author adverted to the rise of the present epidemic, which he dates from the 21st March, 1844, when the weekly deaths by small-pox suddenly rose from twenty to thirty, and have continued (with some irregularities) progressing from that period to the present.

The admissions into the Small-pox Hospital, in 1844, amounted to 647, exceeding by one the admissions in the great epidemic of 1781, and being, with the exception of 1838 (when the epidemic raged throughout the entire year), the greatest number ever received into the hospital since its foundation in 1746.

The character of the disease was severe. The deaths amounted to 151, being at the rate of $23\frac{1}{2}$ per cent. In 1781, when the same number of patients were admitted, the deaths were 257, being at the rate of 49 per cent.

Of the total admitted, 312 were reported

to have been vaccinated, and had cognizable cicatrices; 22 professed to have been vaccinated, but no scars were detected; two alleged, but on very unsatisfactory grounds, that they had been inoculated for small-pox in early life. Among the 312 vaccinated, more than 100 had the disease in the very mild form usually called the varioloid; in a certain number no mitigation was observed. Of the whole number, 21 died, being at the rate of nearly 8 per cent. on this section of admissions*.

A remarkable feature in the history of the past year was the increasing desire on the part of the public for revaccination.

Founding his views on the now indisputable fact, that small-pox spreads as widely *without* as with accompanying inoculation, and on the now equally established fact, that small-pox after vaccination proves fatal at the rate of 7 per cent., while inoculated small-pox is fatal only at the rate of one-fifth, or 1 in 500, the author proceeded to argue that it is unwise to prevent variolous inoculation *in toto*. Persons verging on puberty might, he said, with great prospect of advantage, be inoculated *after vaccination in early life*. If, as happened in the case of his own son, the inoculation failed to produce constitutional symptoms, the permanent security of the party was fully established; on the other hand, if febrile symptoms followed, the disease would probably be mild, and, at all events, would be undergone under the watchful eye and care of parents. As it is, the disease is often received at a period of life the most distressing, as by young women on the eve of marriage, by mothers in confinement, or by young men just embarking for India.

The author instanced a variety of other important objects which might be gained by a repeal of that part of the "Vaccination Act" of 1840, which prohibits qualified medical practitioners from inoculating in England and Ireland, and he concluded by recommending to the legislature such a measure, and to the medical profession (when such permission may be granted) the establishment of a system of infantile vaccination, strengthened and made *doubly sure* by adult inoculation. The practice of *inoculation* might usefully be restricted to the period of life extending from the age of 10 to 20.

Dr. Webster eulogized the paper of Dr. Gregory, which contained matter of great interest. It was not his intention to controvert the opinions expressed in the paper, but one inference of importance he drew from it, viz. that the public, whatever the opinion of some might be, had more confidence in the protective power of vaccination

* Many of the cases received during the year displayed features of individual interest. A variety of them were stated in detail.

than formerly. This was evidenced by the greater number of applications for revaccination at the Vaccination Hospital during the past than in any previous year. Had Dr. Gregory seen many cases of small-pox following revaccination? He, Dr. W., felt strongly on the subject, and was most unwilling to doubt the influence of vaccination, if properly performed. To shew its protective power, he mentioned the fact, that small-pox had been lately prevalent in Bethlem Hospital, and that the only person who had fallen a victim to the disease was a lunatic, who had not been vaccinated. He attributed the occurrence of variola in that establishment to its being epidemic in the neighbourhood, and to the prevalence of westerly winds wafting the contagion into the hospital. The proposition of Dr. Gregory to revive the old and illegal practice of inoculation required mature deliberation. He thought that Parliament was not the best tribunal to settle disputed points in medical practice. Cases might occur in which inoculation might be advisable, but the practice should be confined to qualified persons, and great care should be taken to prevent the dissemination of the disease.

Dr. Gregory, in reply to the question of Dr. Webster regarding the power of revaccination, referred to a case, detailed in his paper, of a girl named Eagle, who was vaccinated in infancy, and, at a later period, revaccinated with great care. Small-pox subsequently attacked her, and she was admitted into the Small-pox Hospital. This case was by no means a solitary one. The objection might be urged that neither the vaccination nor the revaccination had been properly performed in this case. He did not agree with Dr. Webster that the small-pox was introduced into Bethlem Hospital in the manner he had described.

Mr. Davis (Hampstead) said that he received directions to inoculate the whole of a regiment of soldiers under his care, at Bristol, in 1798. Two of the men had been employed in dairy farms in Gloucestershire, and said they had been vaccinated, and it was of no use to inoculate them. They were inoculated, however, but without any effect. One of the men, indeed, was inoculated thirteen times, and of his own accord slept with others suffering from small-pox, without taking the disease. This was before Jenner had investigated the subject, and made it publicly known. He said that he had vaccinated a baby successfully while its mother had the small-pox; and, although the mother died of the disease, and the infant took the breast as long as there was milk, it remained unaffected. Once, whilst practising in the country, he was requested by the parents to vaccinate part of a family from a particular arm, but he was not satisfied with the ap-

pearance of the vesicles, and refused. In spite of his remonstrances, however, the children were vaccinated from that arm by another practitioner, and when the small-pox was prevalent, he wrote to his successor to make inquiries concerning these children, and learnt that those who were vaccinated from that arm which he had refused took the disease, whilst the others did not. He considered that want of care in the selection of lymph was a common cause of vaccination failing to be a perfect protection against small-pox.

Dr. Macaulan asked Dr. Gregory if he was aware whether any difficulty had been experienced in countries where inoculation was not prohibited in arresting the progress of small-pox?

Dr. Gregory replied that such difficulties had occurred both in Europe and in India. In Naples, particularly, this was the case, and with the view of meeting these difficulties the Neapolitan government had decided on the plan of obtaining fresh matter from the cow, and had at this moment agents in this country to obtain a fresh supply from Gloucestershire, the place where Jenner originally obtained his matter. The same difficulties had been experienced in India, and a volume which he held in his hand gave an account of the late epidemic, and the means taken to arrest it. As the volume had probably not been seen by any of the members, he would read some extracts from it.

"Reviewing the whole history of vaccination in Bengal, I fear it must be said that its progress has been slow, that its operations have been but partially successful, and that its present state and prospects are unsatisfactory and discouraging. Neither can it be denied that public opinion has been unsettled regarding its advantages, and public confidence shaken in its efficacy and permanence as an antidote to small pox—a feeling which is not confined to the common people, but prevails more perceptibly among the better informed and reflecting classes of the community, and is not without participators among the profession itself. Under these circumstances it appears most advisable that a commissioned body of medical men, with a few associates from the general community, should undertake to investigate anew the nature and causes of this state of things in Bengal, and to devise for the consideration of government some new plan, or modification of the present system, which, being founded on definite and established principles, may afford some reasonable hope of greater success. The necessity for such renewed inquiry will be deemed the more urgent when it is observed that, far from diminishing in number, the invasions of small-pox have of late become frequent and

destructive in many towns and provinces of Bengal."

In 1839, Mr. Dalrymple, surgeon, writes as follows:—

"He was sorry to say that there had been too much cause for the mistrust which prevailed respecting the protective power of vaccination, as the number of cases of small-pox among the European officers at Messerabad during the past two years had been probably as great in proportion as among the natives."

Thus writes Mr. Atkinson:—

"So many instances of failure occurring, say two or three, their confidence is shaken or destroyed, for they cannot comprehend or appreciate the value of the chance which even that proportion affords of escape from the small-pox, but disregard the whole, because the result is not absolutely certain. Such appears to be the general feeling on the subject of vaccination among the natives in this quarter."

Mr. Tweedie remarks—"that the natives of India are quite satisfied with the variolous inoculation which has been in use from time immemorial, and they do not see that a preference should be placed on a new European mode that they have found most uncertain."

With respect to the commission, Dr. Gregory thought it would be of service, and might advantageously be resorted to in this country. Impressed with the opinion, he had proposed a commission to Sir James Graham in the month of October, 1844.

Dr. C. J. B. Williams inquired whether the failure of vaccination in India might not be attributable to the injury sustained by the lymph in its transit, and to the influence of climate?

Dr. Gregory replied, that vaccination could only be employed in India eight months in the year, and even during this period there were many difficulties, for the natives did not fail to observe the comparative mortality of small-pox when occurring naturally, and when acquired by inoculation, and the probability of the occurrence of variola subsequent to vaccination.

Looking at the fact that women at a marriageable age were liable, even after vaccination, to the ravages of a disease which might not only deprive them of beauty but of their eye-sight, it became our duty to devise some efficient mode of protection. A combination of inoculation with vaccination was, in his opinion, the best plan to be pursued in India, though not the best, perhaps, in all cases, and he recommended its adoption by the East India Company. Placing inoculation under the superintendence of the government, and restricting its performance to medical men, would be a judicious measure; and, indeed, with some

modifications, would be advantageous in this country.

Dr. Williams had heard nothing to convince him that the arguments with respect to vaccination which were applicable to the natives of India, were equally applicable to the people of this country. He denied the similarity of the cases. In India vaccination was only applicable during a few months in the year, and the prejudice of the natives against it prevented its employment on an extensive scale. The elaborate paper of Dr. Gregory had failed to shake his confidence in the protective power of vaccination; and in reference to revaccination, we were at present without statistical information, to arrive at any conclusion respecting it. Small-pox might occur twice or thrice to the same person, and he had lately heard of an instance, though he did not vouch for its truth, in which it had occurred four times. Now, with reference to the question as to whether vaccination was a sufficient protection against variola, it must be borne in mind, at least such was his opinion, that variola, whether natural or inoculated, and cow-pox, were one and the same disease, differing only in their degree of intensity. The effects would be proportionate to the amount of their morbid power, and it was reasonable to suppose that occasionally the least intense of these might not succeed in so sufficiently pervading the frame as to prevent the occurrence of a future attack. The milder the agent, however, the milder the disease produced; so vaccination produced a mild disease, not liable to spread, whilst inoculation might form a focus for the propagation of natural small-pox.

Mr. Streeter had met with two cases of small-pox in pregnant women, at about the sixth month of pregnancy. They both recovered.

Dr. Gregory had met with such cases on more than one occasion. He did not agree with Dr. Williams respecting the identity of small-pox and vaccinia. Natural and inoculated variola were equally severe, as had been proved by the occurrence of consecutive small-pox after the natural or inoculated disease. There was no more identity between variola and cow-pox than between scarlet fever and measles. He related a case in which the elderly parents of a young lady suffering from small-pox were vaccinated, and though they had both submitted to inoculation in early life, the cow-pox went through its natural course. Vaccination being thus successful at a late period of life, and subsequently to inoculation, affords a strong proof of the non-identity of the two diseases. Many facts might be adduced in support of this non-identity.

Dr. C. J. B. Williams thought Mr. Ceeley's experiments conclusive in favour of the identity of cow-pox and small-pox. The

cases related by Dr. Gregory did not militate against this identity to a greater extent than did the occurrence of small-pox after vaccination.

Dr. Webster regarded the case related by Dr. Gregory in the light of a strong proof of Dr. G.'s faith in vaccination. He attributed the frequent failure of cow-pox in preventing variola, to impurity of the lymph, and the carelessness with which vaccination was occasionally performed.

Dr. Stewart referred to a number of cases which had recently occurred in St. Pancras, in support of the sufficiently protective power of vaccination when properly performed. He confirmed, from ample experience, the statement of Dr. Cowan, that in Glasgow small-pox was perpetuated chiefly by Highlanders who had not been vaccinated. Why should we expect, as M. Chomel had said, "more from vaccination than from small-pox itself," for we know that small-pox might occur twice or thrice, and destroy the individual at last.

Dr. Gregory remarked that as half the children in Liverpool died before puberty, and three out of ten of those now in London never reached adult age, still nearly one-half of the population would be protected by vaccination, even if his (Dr. G.'s) plan were fully carried out.

ELECTION OF FELLOWS OF THE COLLEGE OF SURGEONS.

To the Editor of the Medical Gazette.

SIR,

IT is evident that the Council of the College of Surgeons did not intend to legislate so much for this as for future ages. The general practitioners may be very jealous of the present Fellows, but there are many of the latter who do not feel the fellowship a great boon to them. On the contrary, they feel they have lost rather than gained by it: for instance, those who, from their position in the profession, were almost certain of being elected on the Council, now are not only obliged to undergo a strict scrutiny, but also run the risk of being black-balled, or at least being shown that they have many enemies, which is not, it must be allowed, a very enviable feeling; for we all, no doubt, have enemies, but few of us would like to know it. This can be judged of by the last election—some candidates were black-balled, while those who were admitted into the Council got in only by a small majority. The Fellows, however, have not only this ordeal to undergo, but when they have been successful they are not elected for life; and, as the present Council is constituted, must go out in one or two years, after having paid twenty guineas for their seat. I know

not what profits may attach to the Councilorship, but it appears to me to be paying *very dear* for the honour, and more particularly after having advanced large fees for the diploma.

In future ages, no doubt, it will be more just (and even then a great tax), as the Councilors go out by seniority and rotation, and each Fellow will remain in the Council until his turn to go arrives; but at the present period it appears hard, and not quite a fair regulation. It is true that a Councilor may be re-elected, but the result of such re-election remains to be seen. These observations are not made with any view of complaining of the present Council, because they were originally elected for life, and it is just to them it should remain so; but they are intended to show to the Members that the Fellows have not obtained such great advantages as they imagine, and that those of them who are eligible to the Council have rather lost than gained by the new charter. In the time of the old Council, when once elected, nothing could stir you from it; now, in a certain period, you must leave it, and most probably may never have the chance of being nominated again.

I am, sir,

Your obedient servant,

VERITAS.

Jan. 25, 1845.

IS THE MEDICAL PROFESSION OVER- OR UNDER-STOCKED?

To the Editor of the Medical Gazette.

SIR,

HAVING read Mr. Alfred Taylor's paper on the numerical relation of the medical profession to the population of Great Britain, I think that the thanks of the profession are due to him or any other gentleman who may have time and opportunity to explore these difficult subjects, but I would beg to offer a few remarks respectfully to point out what appears to me an insufficiency in the present amount of data, from which to draw satisfactory general conclusions, and that the prominent statement made of the profession being "overstocked" is not the legitimate conclusion to be drawn from the data already procured. I must put down my thoughts rather in a crude shape, and but briefly, but I am sure, from long observation, that they will be found essentially true, and demonstrated by the present relations of the profession and society at large.

1. I venture to assert that the medical profession is understocked, and that because its remuneration or service is undervalued.

2. To complete the schedule of data upon which to judge accurately, we should have

the average of medical income, and the average of incidental expenses, and these compared too with the relative averages both of the clerical and legal professions. I heard an Inspector of Taxes lately say, that from his experience it required from 30 to 40 per cent. of the gross income to carry on general medical practice.

Another most important datum we want, before we can reason correctly upon this subject, is the average number of persons in the whole population who take medical advice once, or more than once, during the year. If I am not much mistaken, this average will be found much higher than is generally imagined, and if I may make a conjecture (it is but a conjecture) I should say that it is somewhere between one third and a half of the entire population.

If it should be said that the clerical and legal professions have no greater advantages than the medical; I answer, not so. For without entering on the question whether the other two professions are provided for as they ought, it is certain that their public services are far below those of medical men, as well as their respective incidental expenses proportionate to the income. I am not disesteeming the other professions; on the contrary, I think the clerical (not superstitiously viewed) pre-eminently the first; but contrasting the respective amount of laborious and expensive occupation fulfilled towards the public by these three classes, the medical men are entitled to the chief consideration.

It matters not whether the number of medical practitioners be increased, or only the income of the present number enlarged, as in the latter case medical assistants could be more respectably maintained than now; and could assistants be thus adequately supported, the expectation of parents and guardians would not experience that painful disappointment in the professional welfare of their youth, the result of which is the present declension in the number of medical pupils. It may be that the existing medical schools are too many, and possibly might be still too many even if the pupils were greatly increased, but this question does not affect the preceding remarks.

I do not pretend to predict what the end will be of the present agitation in the profession, but I am convinced that any forthcoming change which does not embrace a better provision for the medical profession whatever other good things it may contain, will not so materially improve the profession, as seems expected, nor perhaps do away with the patronage of unlicensed practitioners in some shape. The low remuneration for attendance on the parochial sick seems generally admitted, but can we believe that the salaries for it will be much raised,

if at all? and this circumstance must always involve a large amount of unrequited labour to some part of the profession, and unrequited labour must ever drag along with it natural evils, either to the employer or employed, or both.—I am, sir,

Your obedient servant,

A PRACTITIONER.

Feb. 4, 1845.

DESCRIPTION

OF THE

OPERATION OF LITHOTOMY,

AS PERFORMED BY A NATIVE HAKEEM.

Extracted from the Annual Report of the Sick of the 22d Regiment, N. I. for the year 1842.

By A. ARNOTT, M.D.

[Presented by the Medical Board, May 1843].

HAVING had no occasion to perform any capital surgical operation myself, it may not, *pro hac vice*, be entirely out of place here, though not pertaining to my official charge, to describe an operation for lithotomy performed in my presence by a Native Hakeem on a boy about 11 years of age, who had for some time suffered under the severest symptoms of stone in the bladder. No preparatory course of medicine that I am aware of having been gone through, the first object was to ascertain the existence of the stone, and to bring it down into the neck of the bladder. The Hakeem's assistant took the boy in his arms, and jolted him up and down, allowing him to light on his feet with some violence. He then placed him on the lap of a friend seated on the end of a cot with his arms put under the lower end of the thighs, and his hands held to secure him in this position, which sufficiently exposed the perineum, the limbs being kept separate as much as possible. The assistant compressed the abdomen from above downwards; and the operator having introduced the fore and middle fingers of his left hand, previously well oiled, into the rectum, seized the stone, and made it protrude as much as possible in the left side of the perineum, where, with a knife, the blade of which was a little broader than that of a common penknife, he made an incision proportioned to the size of the prominence formed by the stone, from a little behind the scrotum downwards between the anus and tuberosity of the ischium. He then made several deep incisions, some of which I believe were transverse, to make a sufficient opening for the exit of the stone; and to extract it he used an iron hook, an instrument that gave him more power, and took up less room, than a pair of forceps. Notwithstanding the enlargement of the inner wound two

or three times, considerable force and violence were required, and these he did not hesitate to employ, his principal consideration appearing to be the extraction at all hazards.

The calculus was of the mulberry species, hard and compact, of a spherical form, with an uneven surface presenting prominent pointed tubercles, and weighed upwards of 5vi. There was not much blood lost, and after the operation the thighs of the patient were brought together, and he was allowed to rest for some time. I understand that subsequently he was daily put into a warm bath, and when I again saw him the wound was closed and the urine passed by the urethra. The fee of the Hakeem, who is a Mussulman, and has operated by his own account in hundreds of cases, and who also professes to cure hæmorrhoids, was 10 rupees and rations for ten days for himself and his assistant.

There is nothing new or strange in this operation, for it was practised upwards of 2000 years ago. It was the similarity in the most minute particulars of the operation described by Celsus that struck my attention, and makes it worthy of notice. The position of the patient was the same, "*redactisque ejus cruribus, ipsum, quoque jubet, manibus ad suos poplites datis, eos quam maxime possit, attrahere.*" The instruments were exactly the "*scalpellum*" and "*uncus*," and the after treatment corresponded even to the warm bath. "*Deinde interpositis duabus horis, in solum is aquæ calidæ resupinus demittendus est,*" &c. In short, every step in the operation performed by this Hakeem was described by Celsus.

Calculus is by no means so rare in India, as, on the authority of Dr. Scott, it is stated by European writers. A man was brought in to me from a village in the neighbourhood with a stone impacted in the urethra, about an inch from the orifice, which I succeeded in breaking and extracting, and I have often removed stones from the urethra of children. This Hakeem states that in many districts of Candeish there is not a village he goes into where he does not find a case for operation. It is rare in Sepoys, because their period of life is not that which predisposes them to it. A diet containing very little azote may not be favourable to the production of the lithic acid diathesis; and still a tendency to form phosphate and oxalate of lime deposits may be owing to the use of vegetable and farinaceous food.

OBSERVATIONS ON THE COMPOSITION OF A NEW SPECIES OF CALCULUS,

FOUND IN THE KIDNEYS AND THE URETERS
OF A BITCH.

BY M. LASSAIGNE.

THE author of this memoir, published in the *Journal de Chimie Médicale*, for 1828, a detail of the analyses of various urinary concretions occurring in the dog. He showed that many of these were analogous in composition to those found in the human bladder; and inferred from thence a manifest conformity as regards the different functions of man and certain of the lower animals of similar organization. The remarkable feature in the present research is, that the calculus consisted of two organic principles, one belonging exclusively to the products of the renal or urinary secretion, the other only met with heretofore as a secretion of the liver. He has, therefore, very properly called it *urino-biliary* calculus. This fact, which seems unique in the history of concretions, merits the attention both of the medical practitioner and of the physiologist.

The animal which formed the subject of this observation was a bitch of large size, a sort of bull mastiff, which died in the hospital of the school at Alfort, from dropsy.

The cadaveric inspection was made by M. Prudhomme, who discovered in the kidneys, the ureter, and the bladder, a considerable number of small calculi, very irregular in shape, of a beautiful grass-green colour. Among other changes, it was remarked that the renal substance presented a faint yellowish tint, the liver contained in its texture little whitish granulations of phosphate of lime, and small well-defined cysts, of the bigness of a pea, filled with a soft matter of a greyish green, formed of half coagulated albumen, mixed with a little of the green principle of the bile, phosphate and carbonate of lime.

A portion of these calculi was carefully dried and pulverized; the powder emitted a slight urinous smell, and had a marked greenish yellow hue. In this comminuted state even boiling alcohol did not seem to act sensibly as a solvent, although the liquid assumed a pale green colour. Sulphuric ether afforded the same result. In order to determine the nature of the substance held in solution by these liquids, they were evaporated after being mixed. The residue after evaporation was a minute quantity of resinous like matter, of a fine green, insoluble in water, and which, by contact with dilute nitric acid, immediately changed colour; it became bluish, next violet, and lastly bright rose, by prolonged action at the ordinary temperature; this last colour finally changed

to orange yellow. All these effects of successive coloration induced by this acid, denote positively that the small quantity of green matter taken up by the boiling alcohol was the green substance of the bile, or *choleochrome*.

The feeble action exercised by alcohol on these calculi led to the substitution of a solution of caustic potash; this liquid, even in the cold, dissolved almost in totality the mass, and disengaged at the same time a strong odour of ammonia. The alkaline solution had a fine greenish yellow hue; saturation with acids occasioned a copious flocculent precipitate, of a greenish white, which, left to itself, was found reduced after the lapse of some hours to a greenish crystalline powder, composed of small flattened needles arranged in crosses. Microscopic examination having led to the belief that this was uric acid, the fact was verified by treating it along with nitric acid at a gentle heat, and evaporating to dryness; whereupon the characteristic carmine tint of murexide was obtained.

The uric acid, which the potash menstruum had dissolved, was combined in these calculi with ammonia, as shown by its disengagement above. It may be noticed that this acid, which in a state of purity is white, was here evidently combined with a certain quantity of the green colouring matter which neither water nor boiling alcohol was able to remove. After several attempts, however, it was completely separated by re-dissolving in a minimum of the potash solution, and adding to the liquor eight or nine times its volume of alcohol, at a temperature of 190° Fahr. This caused directly an abundant white flocculent precipitate of super-urate of potash, there being held in solution the green colouring matter combined with potash. By means of filtration and saturation with weak acetic acid, this matter was entirely withdrawn from the uric acid.

The above analysis, carefully repeated on a given portion of these calculi, yielded the following results, abstractedly of the order in which the principles are combined: uric acid 62.5, green matter of the bile 12.1, ammonia 25.4, traces of phosphate of lime and carbonate of soda, in 100 parts; or, taking the order in which the principles ought to be distributed, urate of ammonia 87.9, green matter of the bile 12.1, phosphate of lime a trace, in 100 parts.

These calculi, then, are not only remarkable for having uric acid as a constituent, a thing of rare occurrence in the canine race, but for having it associated with a principle peculiar to the hepatic secretion. This mixed composition would seem to favour the idea that in certain pathological states the urinary organs and the liver are so closely dependent upon each other, that the functions

of the one might sometimes supply those of the other, as indeed certain physiological and pathognomonic phenomena tend to establish.—*Bulletin de l'Académie de Médecine*, Dec. 1844.

VALERIANATE OF ZINC.

THIS seems to be the antispasmodic *à la mode*. It was first prepared by Prince L. L. Bonaparte. It is obtained by saturating valerianic acid with very pure and fresh precipitated oxide of zinc, in a crystalline form, as brilliant pearly scales, very bright and of dazzling whiteness. It is neutral, more soluble in hot than in cold water; soluble also in alcohol, ether, and oils.

According to M. Devay, the valerianate of zinc has been employed successfully in cases of facial and intercostal neuralgia, in megrim, and other affections of a *purely* nervous character. It has also been tried in epilepsy. The dose is from one and a half to four grains in the day. M. Cerulli, of Parma, is stated to have cured three cases of neuralgia (supra and infra-orbital) by administering this salt at the period of the attack, in the dose of a grain and a half daily, divided into two pills. By continuing the medicine in the above quantity a complete cure was effected in one patient after 30 days; in another after 40 days; and in the last after 50 days had elapsed.—*Annuaire de Thérapeutique*, 1845.

URIC ACID EXCRETED BY BUTTERFLIES.

ACCORDING to Heller, butterflies excrete more uric acid in proportion to their bulk than any other creature. It is chiefly the product of the metamorphosis which goes on in the *pupa*; the reddish or yellow liquid which butterflies void during or after emerging from the pupa into the perfect state consists principally of urate of ammonia.—*Oesterreich. Medicin. Wochenschrift*, 1844, p. 1048.

UNIVERSITY OF ST. ANDREWS.

THE Senatus Academicus of the University of St. Andrews have issued a confutation of various aspersions relative to their system of medical graduation, published in the last number of the Edinburgh Review. To the assertion there made, that "rejected or despairing candidates of Edinburgh, or of other schools, find a ready outlet at St. Andrews," they give a peremptory denial, and declare that it could only have proceeded from ignorance, or wilful perversion of the truth.

STATE OF THE THERMOMETER,
DURING JANUARY 1845.

To the Editor of the Medical Gazette.

SIR,

I ENCLOSE a record of the state of the thermometer at this place, within doors, and also at Brixton Hill, near London, during the last month, and if you think it likely to interest your readers, I shall be obliged to you to insert it in the GAZETTE. The thermometer at Torquay was placed in a small dressing-room, not communicating with another room, and having no fire-place, and was generally observed about half-past 8 A.M. That at Brixton Hill was noted daily about 8 P.M. and was in a spacious bed-room, having a fire-place, but at no time during the month was there a fire in it.—I am, sir,

Your obedient servant,
C.

Torquay, Feb. 3, 1845.

CLINICAL LECTURE
ON
DISEASES OF THE SPINE.

By SAMUEL SOLLY, F.R.S.

Senior Assistant-Surgeon to St. Thomas's
Hospital.

ON the last occasion that I called your attention to the subject of diseases of the spine, I pointed out an important distinction between the two classes of diseases to which this portion of the frame is liable; and those who feel interested in recalling those observations, will find them published in the 31st volume of the *MEDICAL GAZETTE*. In both forms of disease the spine is distorted, and the human frame is consequently more or less deformed; but in the one the curvature is from side to side—the *lateral curvature*; and in the other from before backwards—the *angular curvature*. In the first the deformity arises chiefly from a want of power in the muscles of the back, and the ligaments of the spine, to sustain it in the perfectly erect posture, and it bends into the form of the letter S, being at the same time twisted on its axis.

In the angular curvature, the deformity arises from the absorption of one or more of the bodies of the vertebrae, which, allowing them to fall forward, causes the spinous processes to protrude, and form a projecting angle posteriorly. The spinal canal is diminished in size; and from this cause, together with inflammation and thickening of the sheath of the chord, the nervous columns are pressed upon, and paralysis ensues. In the first case the muscles of the spine require to be exercised, and motion, with intervals of rest, and tonic medicines, are required. In the second, absolute and entire rest, with caustic issues, and sometimes mild mercurials, are necessary to arrest the disease, and save the spinal chord from destructive softening.

Nothing, then, you will perceive, can be more important than to distinguish these two classes of cases, requiring, as they do, such opposite modes of treatment. And if their diagnostic marks were always as clear and simple as they appear in a statement of the characteristic differences of the two diseases, nothing would be more easy and simple; but such is not the case. There are cases in which these characteristic differences are not so clear and evident, in which the lines of demarcation are broken down, as it were; and it is to this practical point that I wish to direct your attention. We have now a patient in the house, whose case I will read to you in a few minutes, with a lateral curvature, arising from caries of the spine, and the pathology of which was overlooked by a spine doctor into whose hands he fell when first taken ill, who treated it as a case simply requiring support; and he supplied him with a pair of stays, which he wore until he became almost paralytic.

Isaac Cripps, æt. 21, printer's devil; came to the hospital complaining of difficulty of breathing and weakness of his legs. Not believing that it had any thing to do with his spine, was admitted under one of the physicians who, having examined him, detected its real origin and seat, and sent him up to Isaac's ward, under Mr. Green, October 15th, 1844.

Short, but thick set; rather of a scrofulous appearance; thin skin; a good deal of colour. Complains of great weakness in his lower extremities, especially of the left leg, which has not power of itself to support the weight of the body. He could walk with difficulty, and not without support, dragging the left leg after him. Has not lost all sensation; his thighs are normally sensitive, but his feet and lower parts of his legs feel numbed and cold, with the sensation of needles and pins in his feet, and has frequently sudden pains in his legs, which make them draw up involuntarily. Pain in

the spine about the seat of curvature, which appears lateral, and about the situation of the sixth dorsal vertebra; he cannot lie on his back without pain, nor can he, when standing, balance himself properly. The curvature is towards the left side, and there is very little corresponding curve in the lumbar region. The thorax is also enlarged on the left side, about the same situation anteriorly; it projects on the right side, and towards the mesial line. The median line anteriorly presents a double curve.

Has worked four years at a printer's, putting newspapers on to the machine; this they effect by swinging their bodies over towards it; and to prevent their falling, from too great a swing, a high board is placed.

Two years and a half ago he was moving a large piece of iron with another man, when it fell down and struck his thigh, and knocked him violently against the wall; since that he has been much worse, but continued his work as before. He had an apparatus made for him, which he wore nine months; then left it off because it hurt him. He then got worse, and was unable to go on with the work, so went to another part of the business, to count off the papers, less laborious. Has felt the loss of power for four months.

16th.—Ordered by Mr. Solly—Spine to be painted with Tinct. Iodinii, and to take the iodine mixture with gentian.

26th.—Caustic issue.

Nov. 16th.—The legs, the left especially, have lately been drawn up at night involuntarily, and he has not power to straighten them. The nurse is obliged to replace them.

Another issue to be made near the seat of curvature.

Dec. 14th.—Pulv. Doveri, gr. viij.; Cal. gr. ij. omni nocte.

21st.—Has lately felt severe pain in his knees; is now much better; has felt much more power, as well as warmth in his limbs.

Another moxa to be made near the first, over the lumbar vertebra. Calomel increased to gr. iij.

Jan. 4th.—Another moxa was ordered to-day. He finds himself very much improved; his legs and feet have regained their normal sensibility, and he wants to get out of bed, saying he is quite strong enough.

13th.—Mouth first affected with calomel.

20th.—Discontinued, on account of the mouth being very tender; and all symptoms of paraplegia having ceased, he is very anxious of leaving the hospital, but Mr. Solly has persuaded him to remain quiet in bed for the present.

The first point to remark in this case is, the constitution of our patient. You will remember that it is strumous, and predis-

posed, therefore, to carious disease of the spine, in the event of this portion of the skeleton being injured. This man says that his attention was not called to his spine until he received the blow mentioned in the report; but he now remembers that he used to feel aching pains and weakness in his back previously. It is therefore most probable that some degree of diseased action had been induced in the bones by the constant exertion to which the column was exposed by his peculiar occupation, and that the blow merely aggravated what had been already lit up.

Mr. Pott, who has written a most interesting treatise on the connection between palsy of the lower limbs and curvature of the spine, makes some admirable observations on this point; he says (vol. iii. p. 425), "That although it sometimes happened that a smart blow, or a violent strain, had immediately preceded the appearance of the curve, and might be supposed to have given rise to it, yet in many more adults it happened that no such cause was fairly assignable, and that they began to stoop, and to falter in walking, before they thought at all of their back, or of any violence offered to it. That exactly the same symptoms are found in infants, and in young children, who have not exerted themselves, nor have been injured by others, as in the adult who has strained himself, or received a blow; and that the case was still the same in those grown people who have neither done nor suffered any violence." After adding other facts connected with the pathology of the disease, he says, "All these circumstances put together, induced me, as I have already said, to suspect, when we attribute the whole of this mischief to the mere accidental curvature of the spine in consequence of violence, we mistake an effect for a cause; and that previous both to the paralytic state of the legs, and to the alteration of the figure of the back bone, there is a predisposing cause of both, consisting in a distempered state of the ligaments and bones where the curve soon after makes its appearance."

These views of Mr. Pott are now generally adopted by the profession, and we must not attribute the disease entirely to the accident. Nevertheless, I suspect that the blow materially modified the character and progress of the disease. You will remember, from what I have already stated, that curvature of the spine which follows caries is almost always angular, projecting directly backwards. In this case, I have no doubt the lateral direction of the curve was occasioned by the blow striking the spine laterally, and thus injuring one side of the bodies more than the other, and causing the disease to progress more rapidly on the side of the vertebræ than in the front, its usual seat.

You will see, in this preparation, a lateral direction given to the curve, from the ulcerative process having extended on one side of the bodies only, and though we have no history attached to this preparation to enable us to say that any similar cause excited the disease to take this course, the appearance it presents will assist you in understanding how it is possible it might have thus occurred.

Sir B. Brodie, in his work on Diseases of the Joints, p. 242, relates thus the post-mortem appearances in a case where there was lateral curvature arising from caries:—"There were no remains of the intervertebral cartilage between the fourth and fifth dorsal, and the opposite surfaces of these two vertebrae were ulcerated to a greater extent towards the left side than towards the right, and hence arose the lateral curvature."

You will, then, understand, that you may have a lateral curvature from ulceration of the bodies of the vertebrae.

This patient, you have learnt, suffered from weakness and numbness of the limbs. This weakness and partial loss of sensation arose from pressure on the spinal chord. This pressure has been attributed, by some pathologists, to the acute angle which is formed in the canal from the falling forward of the bodies; but in this case it evidently could not be the cause. I do not believe that it is ever the case, but that the pressure is produced by deposition of adventitious matter within the canal, which matter is in some cases the fibrinous deposit from the inflammatory action of the membranes of the cord; in others, the strumous deposit of the bone which encroaches on the canal. It is important that you should understand this, otherwise you will not appreciate the value of mercury in the treatment of the disease, or understand why this patient improved so rapidly when the dose of that mineral was increased so as to affect his system. As soon as the pressure was removed, his nervous chords recovered their functions. If that pressure had been occasioned by the solid bone, it could not have been so speedily removed. But we must not pass over, in our consideration of the treatment, the effect of the moxa. To Mr. Pott we are indebted for our knowledge of the value of this form of counter-irritation, and I have no hesitation in saying that its effects are much more decidedly beneficial than an issue made in any other way. You will also find that it is much better to repeat them than to keep them open for any length of time. I generally close them after they have been open for a month. In a case of paralysis from disease of the spine, which I had under my care when I was Mr. Tyrrell's assistant, where the lower extremities had been entirely useless for twelve months, I applied at

least ten moxas, and the patient recovered the use of her limbs so perfectly as to walk well before she left the hospital. In the treatment of all spinal cases you must have patience, and not be discouraged because your remedial measures do not produce an early and decided improvement.

In the treatment of many chronic affections of the eye, especially those in which the retina is implicated, you may give mercury for months without any apparent benefit, till at last you perceive a slight improvement, and by perseverance you are eventually enabled to restore perfect vision, where, by a more hasty plan, the sight might have been destroyed for ever, or left irremediably injured, from a want of knowledge of the fact that a long-continued course of mercury, in very small doses, with counter-irritation, will effect so much.

The next important point in the pathology of diseases of the spine which this case will enable me to discuss is, on the one hand, whether ulceration of the vertebrae ever takes place without any consequent suppuration; on the other, whether or not there is a disease of the vertebrae by which the form of the column is altered, as in caries, but which is not caries. As a general rule, caries of the bones, like ulceration of the soft parts, is accompanied with the formation of pus, and in order to impress this point on your minds, so that you may appreciate the importance of the views I have to bring forward regarding angular deformity without suppuration, I will exhibit a case shewing the ordinary effect of caries with suppuration.

In caries of the spine, the matter sometimes finds its way to the surface in one direction and sometimes in another. Here is a cast of the back of a poor child whom I saw among the out-patients about two years ago: he was then five years old. The angular curvature of the dorsal vertebrae is very distinct: a little below, and on the right side, almost in the lumbar region, you observe this large rounded swelling, about as large as a child's head. This was an abscess. It was opened carefully with a valvular aperture, and then closed again. About two pints of matter were removed. The child's strength was supported with nourishing diet and tonic medicines; the parts kept as much at rest as possible; the abscess painted with the tincture of iodine; and the result has been that ankylosis has taken place, and the poor little fellow, though much shortened in stature, and deformed, is a cheerful happy boy, whose principal fault, his mother tells me, is that he will never be quiet, but is always running about. However, you shall see him for yourselves. [The patient was then brought into the theatre].

The opening of the abscess has not quite

healed yet, and occasionally discharges a small quantity of pus, but he is quite free from pain in the spine. I have brought this case before you with a double object: first, as exhibiting the abscess which is occasioned by caries of the spine, and secondly, in order to encourage you in the treatment of this disease, even where the collection of matter is excessive, and the patient, worn almost to a skeleton, seems on the very verge of the grave. When I first saw this case I certainly believed it to be utterly hopeless, but of course I did not tell him so or his friends, and we have been rewarded for our trouble. Do not despair yourself—and do not take away hope from your patient.

This case merely exhibits one of the many forms and directions which the abscess assumes in this disease, and as we have other cases in the house which illustrate the disease still further, such as psoas abscess, &c. I shall call your attention to these diseases at a future time, and we will now return to the consideration of angular curvature of the spine without suppuration. My attention was first called to the existence of such a disease by Sir B. Brodie. He described it to me under the title of rheumatic caries. I have seen two cases of it; both in the persons of medical men. They are both deeply interesting and instructive. In the first case, the true nature of the disease was not discovered until it had existed twenty years, and deformity had occurred; it was then that I first saw him professionally, and learnt from Sir B. Brodie his opinion. Shortly after this, I saw the second case, and from my knowledge thus acquired I discovered its real nature, and had a consultation with that eminent surgeon regarding it. He confirmed the view I had taken, and the result of the treatment you will find has been his restoration to health. In my friend's own words, which he has kindly sent me, I will give the first of these cases.

A. B.—“My illness began in 1825: I cannot tell why, but I experienced a pain on the right side of the seventh or eighth dorsal vertebra, for which I was cupped, and which has continued to recur at intervals ever since. My mode of life at that time was not, nor had it been for many years previously, (1813) such as to preserve health. I was exsanguineous, irritable, and thin—chlorotic. In 1826 and 27, I became more sensible of illness, especially in the autumn, and was occasionally laid by with fever and inflammatory symptoms, affecting chiefly the cerebro-spinal system. I should call this the inflammatory stage, and I believe that if it had been discovered at this time, and properly treated by local antiphlogistic remedies, change of air, &c., followed by a course of tonics and chalybeates, with a regulated diet,

it is my conviction that my present premature decay would have been prevented. As it was, the pain in the back was classed among the general symptoms of fever, and treated accordingly, or rather overlooked, for it was called ague; the immediate urgency was subdued by cupping, bleeding, &c. &c. The disease was reduced to a subordinate form, and the lesser symptoms of its progress left unperceived or unappreciated. These inflammatory attacks happened almost periodically from 1827, 28, 29. In 1830, I suffered from anasarca, with occasional pain and debility, and it was called debility with dorsal pain. 1831, 32, were tolerably quiet: severe attacks (spring and autumn) both of which demanded very firm and peremptory depletion. From this moment I date the decline of my strength—the vigour of youth departed (aged 29), and I was conscious that my health was sapped, although I was not aware in what manner, beneath the very centre and citadel of life.

This closed the inflammatory period. But the succeeding attacks were still severe, and of a mixed character, tending rather, although not entirely, to asthenic symptoms. I was conscious now of being weak in the back, at a particular point, eighth dorsal.

In 1835, I could not throw up the sash of a window, and dreaded putting on my boots. A midwifery case was torture to me, so was compounding medicine, or walking far, or a rough cab. Any one leaning on my arm was painful, and I stooped in walking. It was considered now that I had rheumatism of the costal and intercostal muscles.

In 1836 (Sept. and Oct.), I was seized with acute pain in eighth dorsal, fever, pulse 120, bad nights, costiveness, &c.: it was called rheumatic ague. There were spasm of the diaphragm, almost stopping the breath, chronic spasms of all the muscles of the trunk, coming on in epileptic spasms as it were, tearing, rending, grasping, and almost squeezing the breath out of my body; to laugh, cry, shout, speak, or turn myself, was utterly impossible till the paroxysm had passed. Often have I waited up stairs till the turmoil was over, then bandaged myself up tight with flannel roller, taken some laudanum, put on my great coat, and gone round to see my patients, and come home again to make up my medicine. Frequently at night a sharp pain would plunge through the spinal chord at the eighth dorsal like a knife, and cause me to twist round involuntarily in bed like a reptile. This state of things continued 1835-36-37, presenting the same features, more or less intense, which no one understood, and for which I was cupped, leeches, blistered, mer-

curialised, salined, diaphorised, antimonialised, barkified, depleted, dieted, fed up, fed down, at each several recurrence of the disease—all to no good, because everything was done at random, no one knew why or wherefore, while every one gave an opinion which was exceedingly good, save and except that it never once related to the real nature and seat of the malady. During this period, the bladder and the appendant organs began to be involved in the progress of the disorder, and phosphatic urine began to appear, and sometimes serous urine of a very low specific gravity.

In 1838, the evils thickened. It was utterly impossible to turn round in bed without making a previous preparation of the arms and legs; the pulse 92, the eighth dorsal always acutely sensitive. It was almost impossible to walk, or, if walking, to draw up on a sudden; to jump, leap, sneeze, or run, was quite impossible—I never attempted them. I was often hallucinated, and was sometimes unable to distinguish in my memory between dreams and realities. Yet I kept to my business (as well as I could), wore a bandage, took opium, and often went my round with a pulse at 120. I thought that death was staring me in the face, and I prepared to meet it. I consulted very many this year, but no one was sagacious enough to detect the disease; they prescribed and encouraged me, but in fact left me to myself. In the autumn, I covered my back all over with an ointment composed of ung. hydr. fer. pulv. opii, and cerate; this gave me relief, and I blessed the thought. Also this year I took, at different times, two pints of vin. ferri, and bottled porter also, which did good. About November, the eighth dorsal projected, and solved the mystery, pointing like a sign-post to the truth, which no one had hitherto been able to divine. By December of this year I was comparatively well, or at least easy, and 1839 began with cheering prospects.

From this time the inflammatory stage ceased, and the asthenic condition was fairly established. The nerves were shaken, the legs not so firm as they had been, and the bladder, &c. declined in power. But my spirit was now broke in, and I had learned to bear pain without complaining of it. Neither did I often consult any one about my ailments, as I looked upon obtaining relief as hopeless.

For the last five years I have never been entirely free from pain, while conscious of gradually losing power. The urine became gradually more phosphatic, the assimilative process more and more deranged, the difficulty of getting about greater and greater, and paraplegia more and more imminent,—till I was laid on my back, unable to rise,

August 1843. Thus my long and tedious illness was brought to a crisis, which forced me from the practice of my profession, and compelled me to pack up my tatters, and decamp as well as I could. I had long foreseen this extremity to which I was reduced, and was therefore better prepared in mind to meet it than most persons supposed. My plans were laid two years beforehand.

At this time all the symptoms were those of extreme debility—I was prostrate, and crippled, and I came to Brighton.

I was on my back, unable to be up for more than half an hour. At night I was in bed. I kept lying thus from August 1843, to January 1844, when my strength began to return. In December 1813 I was at my worst; pulse 100 and weak; wasting of flesh; costive bowels; bad appetite; sleepless nights; hæmaturia; œdema of the hands, face, and feet. During this period my strength was of course exhausted, but my appetite was voracious, yet neither wholesome nor agreeable. I required a great deal of porter, wine, or even brandy, and I was always thirsty, especially at night.

Pulse 92, weak and sharp; when lying down or standing up, much quicker. Skin dry and pale, especially the hands and feet. Tongue always clean but pale, marks of teeth in it. Mind perfectly self-possessed. Sleep bad. Drowsy at night, but awake at two or three o'clock unable to sleep again; often awoke in the night so exhausted as to be obliged to take brandy. Urine copious, pale, with a deep phosphatic deposit; often at 0, like hysteric urine, generally 4°. Sweet odour, unlike that of urine albuminous. As it rose in specific gravity, hæmaturia appeared, and alternated with lactic acid deposit. Always a good deal of cloudy mucus; and the urine when left standing became ammoniacal.

Numbness of the right leg, as high as the top of a Wellington boot. Both legs jumped involuntarily day and night. These startings took place thus: an electric spark (as it were) exploded on the foot, shin, or thigh of one leg, and instantly afterwards both legs jumped. At night they would be subject to subsultus so violent as to awake me in alarm: numbness of both legs always followed this subsultus. The right arm at times was subject to involuntary jerking, as if somebody pulled it with a cord. Also the head was at times jerked forwards involuntarily. I was fatter at that time than I am now. My back was very tender—skin (I am told) over the diseased portion suffused with a blush. My sight was defective, which is usually very keen. Double vision of right eye.

The numbness of the right leg, and the dimness or biopia of the right eye, are now entirely gone, and I have no knowledge of the one or

the other, except when, which is seldom the case now, the stomach is disordered, or the mind stretched.

On the 2d of January, 1844, I felt considerably better; got up, dressed and went out as far as the bottom of the Marine Parade is from the New Steine. From Jan. 1844, till February 1845, I have been on my back less and less, but I cannot sit in any chair but the one you saw. Nor can I go through the fatigue of a "visit" in an evening or so, without paying for it the next day so severely, that I am not inclined to repeat my gaiety. I am never quite easy unless I spend the day quite after my own fashion, *i. e.* a perfect recluse. My life is one of pain, inconvenience, and bodily trial, to this hour; anything beyond my reach is a difficulty to me, a person jolting me, or turning round, or stepping far. Nevertheless, I can walk for about three hours a day, a loitering walk; I *can* walk five or six, but with repentance. Not long ago I walked seven miles, but my legs became giddy, and I was forced to ride home in a fly which was fortunately close at hand. I am always better when I do not walk much, and the bowels act better; I require about twelve hours' bed. In this manner I keep well: what a limited existence! But a living dog is better than a dead lion! It gives me leisure to revolve my philosophy, or my religion, and to ponder on the end. "*Adolescentulus ego sum et contemptus; justificationis ejus non oblitus.*"

The recovery has been complete up to a given point—the back is stronger, the disease, I believe, has ceased to make progress, and the assimilative functions are restored in tone. But I must be very well aware that my constitution has received a shock which has penetrated to the centre, and that for the rest of my days I must be content to retain my health upon a tenure certain of being forfeited to the slightest inadvertence. Unless he is prepared to be charged with ignorance of the first principles of pathology, let no medical practitioner who pretends to any skill in his profession superficially suppose that a spinal case is a curable malady, or shut his eyes against its existence as an evidence, in fact, of a deeply-seated constitutional derangement, irremediable, progressive, and fatal—if it have not been recognised in its very first symptoms.

With regard to treatment:—

In the acute stage (1825—1838) the antiphlogistic treatment was only so much powder and shot thrown away, and rather tended to injure my constitution than to dislodge the enemy within it, by always having been aimed at the wrong mark, if aimed at anything; but afterwards, when blood was abstracted from the region of the spine, I always found benefit from it. The local ap-

plications which were of use were ointments composed of spermaceti, opium, and Ung. hydr. fort. spread upon lint, and covering the back; soap cerate always spread upon calico in winter, and the tincture of iodine.

In the asthenic stage (1839—45) iron stands at the top of the list as the most congenial to the disease, and the most to be relied upon; the *tinctura ferri muriatis*, and the *vinum ferri*, in small doses; nitric acid, quinine, and brandy, in some modification or other: good sherry is almost indispensable. The best aperients are aloe, with rhubarb, ginger, myrrh, galbanum, and the essential oils. Blue pill occasionally. The acid stomach is best corrected by tonics. Opium is always requisite. The chronic pain in the diseased bone is best alleviated by a sponge steeped in hot water, and held to the anus—I cannot tell why.

The medicines which disagree—

1. Salines, mercurials, iodine, hydr. potass. alkalies of all sorts, all infusions with mucilage—even beer disagrees on account of the mucilage—comp. decoct. *sarsæ* disagrees on this account. 2. All cold applications disagree. A draught of cold water at dinner will cause pain for the rest of the evening; cold bathing very pernicious, and cold ablutions.

Diet.—High, sustaining diet, without forcing the circulation. The only diet which really suits is plain roast mutton or beef, with bread, and two or three glasses of sherry, or a little brandy; tea, with a great deal of milk, mornings, and bread and butter, and the same in the evening. Every other article of diet either disagrees altogether, or gives rise to unpleasant feelings, acid stomach, and imperfect digestion; puddings, pastry, raw fruits, white meat, bacon, fish (except soles or cod without sauces) desserts of all kind, claret, port wine, all positively noxious. I must except rice, which, like bread, is a staff of life. Genuine bottled porter sometimes agrees very well.

Dress.—The most particular attention ought to be paid to the clothing. Warmth, not merely of dress, but during the time of dressing and undressing, must be carefully observed, especially in winter. It ought to be performed close by the fire, the bed ought to be warmed, and the feet placed in warm water at night, or wrapped in flannel, chafed with the hand, on retiring for the night. The shoulders ought to be protected during the night with a shawl or small flannel jacket. There ought to be no bed-fellow. The breakfast should be taken in bed before rising; warm water used for the hands and face. Cold ablutions (I repeat) are both painful and pernicious, often causing debility and dorsal pain for the remainder of the day. Every article of wearing apparel should be well aired at the fire

before putting it on (a cold shirt will give rise to pain), even before going out; the shoes, the great coat, the neckcloth, should be made warm, so as to carry out a certain quantity of heat buttoned up in the dress. Even in summer, a light cape will never be too much; an entire flannel gait should be worn next the skin, and worsted stockings in winter.

Exercise is not so fatiguing and pernicious as mental exertion, long-continued thought, or family anxieties.

I need not say that Wellington boots are never to be pulled on. The first intimation I received of my back giving way, was pain in throwing up the sash of a window, and next in pulling on my boots. Tying or buttoning shoes ought not to be allowed, nor reaching high for anything. The most painful and fatiguing exertion is the act of shaving, even to this day: I am positively almost inclined to abandon my beard, and come out like a regular Jew, like the author of the "Mysteries of Paris." It would have been fortunate for me if I had been born 300 years back, when beards were all the go.

Of the condition of the generative system in spinal disease.—In primo accessu hujus deformitatis, intacta vis genitalis est. Ille morbo vero durante, plerumque post paucos annos, quum jam medulla spinalis quodammodo compressa; vertebrarum ossa, ad mollietatem et gibbositatem degenerantia, nervorum facultatem renalium interrumpunt; adeo ut, vis virilis labascit lentè, et gradatim extinguitur, ad propria munera idonea damnata. Tum supervenit senectus precocis, facundumque nihil amplius secerantur semen, a cujus stimulo emasculatus æger omnino absconditur.

Aliquando tamen, excitatio prava, insuitata, ægrotum cum urgenti et inexplebili libidine ad veneris voluptatem instigat: at, chen! non etiam in thalamo, hæc cupido insatiabilis,—hæc fames tam turpis,—hoc modo laudabili per coitum vix eximi possit.

Languente tandem propter debilitatem virium momentum, sanguinis motus e corpore penis spongioso primo defluit, ac denique genitalia organa versus non amplius augetur. Fit impotentia, vel tantummodo sterilitas, aut siquidem potentia re-mansit virilis, singulari tamen lassitudine comitatur coitus.

Porro, interjecto deinde tempore, testes invicem inflammatione subacutâ correptæ, ac dolore diutino invasæ, imprimis tumescunt, tum marcescunt, et postremo tabescunt. Haud equidem rara, ni fallor, hydrocele, itidemque epididymis induratio, consecuti sunt:—suppuratio nunquam.

Non fortuito facta, ut reor, quod ita jam tunc accidunt hæc symptomata in cursu hujusmodi morbi.

You can make use of these remarks, if my dog-Latin be done well enough to go up in class.

I will now transcribe some, of which no one need be ashamed, which comprises the general outline of treatment for spinal disease, not merely for the time being under the doctor's hands, but, indeed, for the rest of the invalid's days. An advanced spinal affection is, in fact, premature old age:—therefore, "pugnandum tanquam contra morbum, sic contra senectutem. Habenda ratio valetudinis; utendum exercitationibus modicis; tantum cibi et potionis adhibendum, ut reficiantur vires, non opprimantur. Nec vero corpori soli subveniendum est, sed menti atque animo multo magis. Nam hæc quoque, nisi tanquam lumini oleum instilles, extinguuntur senectute, et corpora quidem defatigatione et exercitatione ingravescent; animi autem exercitando levantur —."—*Cicero de Senectute*, xi. 14—20.

This is the sum and substance of the medical treatment.

Yours, &c."

As our time has now expired, I must postpone to our next meeting the relation of the second case, and my views regarding the pathology of this interesting disease.

OBSERVATIONS ON THE NATURE AND TREATMENT OF THE MORE IMPORTANT DISEASES OF THE NERVOUS SYSTEM:

With Illustrative Cases.

BY EDWARD BLACKMORE, M.D. Edinb.
Member Extraordinary of the Royal Medical
Society of Edinburgh, and Physician to
the Bath Penitentiary.

(For the *London Medical Gazette*.)

[Continued from page 602.]

Successful Cases.

CASE XI.—A man, aged 28, in October, 1822, after dinner felt headache; went to his work, and quickly fell into profound apoplexy. It was the third attack, in the first of which the loss of sense had continued for twelve hours. When seen by me shortly afterwards, the pupils were immoveable, and he was slightly convulsed; the head hot; pulse 80, strong and full; respiration slow and deep. He was bled in both arms to three pounds, when the pulse failed, and he opened his eyes and vomited.

Cold affusion on the head; purgative clysters.

In a few hours afterwards, some stupor remaining, and the pulse strong, and the bowels shut up, he was bled again to 7 ounces, when he became sensible, and vomited freely.

Cold and clysters repeated.

The next day, a little fever, and pain under the frontal bone; bowels costive.

Jalap with calomel, and a stream of cold water on the head; antimony with calomel every six hours, to salivate.

On the 3d day from the attack, heaviness of the head; little sleep; pulse 80; bowels purged.

Medicines repeated.

4th day.—Still little sleep; breathing oppressed.

The 5th day, slight dysentery; gums sore, having taken two scruples of calomel, and the same quantity of antimony, in three days. After this he recovered rapidly.

CASE XII.—A plethoric woman, aged 38, in 1823, when within a fortnight of her confinement, was attacked with severe pain in the head (she had also suffered from pains in the back and abdomen the day before), vertigo, succeeded by transient loss of speech and sense. The next morning the headache continued, with vomiting, and she became delirious, convulsed, and then comatose, with stertorous breathing; the pupils much contracted; the head very hot; pulse 68, very full and strong. Cold water was dashed on the head, and 30 ounces of very sized blood drawn from the jugular and basilic veins. In a few hours the relief was decisive, and purgatives completed the amendment. In two days she was delivered of a dead child, and recovered favourably.

CASE XIII.—A woman, aged 24, five weeks after a natural confinement in the autumn of 1824, got occasional attacks of epilepsy, for which a small quantity of blood was abstracted, and turpentine clysters given, by which she was sickened and purged. I saw her September 29th, when she complained of a deadness in the left arm and leg, pain at the orbits (usually worse on taking beer), occasional loss of sight, costiveness, and cold extremities; the tongue very white; pulse small.

Calomel and purgatives ordered.

The next morning I found her in apoplexy; the face turgid; pupils contracted and immovable; pulse slow and firm. After a bleeding to 30 ounces, and cold washing of the head, she became sensible. A solution of salts then given was vomited. A few hours afterwards the pulse remained at 60, and she complained of acute pain in the head.

A blister on the shaven head; purgatives and calomel every three hours.

The next day a return of convulsions, and of acute pain at the head on the least movement; pulse slow and small; the bowels purged.

Leeches, and a purgative clyster; calomel continued.

In the evening many feculent stools passed, containing tape-worm.

Oct. 2d.—Pain and heat of head continued.

Cold affusion, castor oil, and calomel.

3d.—Costiveness.

Purgatives and cold.

4th.—Great retching after purging.

On the 5th, the stools, that had been unhealthy, became natural. The 10th, able to sit up; occasional pain at head, which was relieved by cold and purgatives. Convalescence continued through the winter to March 1825, when she came again under my care for convulsions and a deadness of one hand, recurring in paroxysms of three days' duration, at intervals of three weeks, without headache; the bowels torpid. The symptoms were relieved in the course of ten days by the use of pills of aloes, galbanum, and mercury; blisters on the back, friction, and the vapour of hot water to the affected arm.

In November, 1827, I found that some months after the former period she became affected with epileptic fits, repeated three times a month, beginning in cramp at the hand, and on the sensation running up the arm, the senses failed. A fortnight after parturition, nine months ago, she had five fits in the night; after which they ceased for six months; and during pregnancy she had none! No menses seen since this confinement, and she was now nursing a fine child. In the last two months she had been bled four times. The existing symptoms, headache, deafness, a mist and flashes of light before the eyes; a weak pulse.

To wean the child. An embrocation on the spine. Pills of sulphate of zinc, galbanum, and opium.

After this her health improved to April 1830, when she came under treatment for ten days for spasms of the arms and eyeballs, which were cured by leeches, a blister on the neck, calomel, purgatives, and six drachms of colchicum wine.

CASE XIV.—A man, aged 65, was afflicted in the beginning of April 1827 with tremors like chorea, succeeded by sleeplessness, confusion of thought, lethargy, a ringing in the ears, loss of appetite, and costiveness; the tongue white; pulse strong. These symptoms continued to May 23d, when I saw him.

Bleeding, purgatives, with diuretics. Antimonial ointment on the scalp.

In a week much relief; the scalp pustulated.

Croton oil, with oil of turpentine.

June 15th.—Head complaints worse since costiveness; pulse 68, full; scalp very sore by the ointment.

Bleeding to twelve ounces (the coagulum loose and convex.) Purgatives.

The next day three convulsive fits, and imperfect palsy of the legs; much headache and sleeplessness.

Leeches and purgatives.

After this considerable relief, but succeeded by despondency and occasional delirium; the pulse 60 when asleep, 70 when awake; the scalp suppurating. In a few days more delirium and sleeplessness, with costiveness.

Purgatives.

Then an hysterical fatuous state; the scalp sloughing; costiveness continuing. In the following week, to July 5th, more fever, delirium, and tremors; the scalp healing. This state continued to the 31st, when, after being costive, he fell into profound apoplexy; the pulse large and strong. He was bled two hours afterwards to fifty-four ounces, before the pulse was impressed; the blood inflamed.

Calomel, jalap, and castor oil.

In a few hours he recovered his senses, but could not speak. The medicines had failed to purge; then full purging followed on repeating the purgatives, and he regained the power of speech.

Aug. 1st.—The purging continued, with great amendment. The next day a diarrhœa, for which opium with tartarized antimony was given.

3d.—Diarrhœa, requiring opium with chalk.

4th.—Pain and swelling at the hypogastrium, although the urining free.

Aperients, and a blister to the abdomen.

8th.—Every symptom better, except the imperfection of speech. By the 17th the power of speech was restored, and he could resume his business as a grocer.

On September 3d, having had a diarrhœa for some days, he took brandy and water at supper, and the next morning breakfasted on fish; after which he became speechless; the pulse full and strong. The abstraction of five ounces of blood was followed by severe tonic spasm of the arm, coma, and foaming at the mouth. Some croton oil was then given, which in a few hours excited vomiting; after which he was much relieved, except that his speech was lost.

The next day severe convulsions and watery diarrhœa.

5th and 6th.—Convulsions.

Purgatives, and a blister on the neck.

Then purged of feculent stools, and speech restored. The amendment continued to the 15th, when he died tranquilly, from gradual exhaustion.

CASE XV.*—A woman, 60 years of age, whose habits were intemperate, but of good general health, was affected, January 22d, 1820, with acute epilepsy. The fit returned in a few days, and she was then bled. When she came under my observation, on the ninth day of her illness, she was delirious; then slightly comatose, and hemiplegic on the right side; countenance fatuous; tongue white; pulse natural. An opiate was given by her medical attendant, after which the mouth was drawn to the left side; the palsy more complete; pulse 88, firm; the bowels very costive.

A blister to the neck; purgatives.

The 11th day, not better, costiveness remaining.

12th day, incoherent; urine passed in bed; costiveness; pulse 96, full and firm.

* This case I saw in the practice of a physician deceased.

Elaterium, one grain every hour; ten leeches to the temples.

After six doses having failed to purge, and the symptoms remaining, she was bled to seventeen ounces; the blood buffy and cupped.

On the 13th day, speech less inarticulate; countenance more intelligent; an attempt made to move the arms when requested, but the muscles rigid, and pain excited by stretching them; pulse 112, firm. Costiveness continuing, after twelve grains of extract of elaterium.

On the 14th day a great improvement, from two copious stools from calomel and jalap.

15th, muscles less rigid; black spots on the sacrum.

16th, voluntary power increasing, but pain still existed on movement.

In five days more the memory restored, and she could walk. Convalescent in three weeks from the attack.

CASE XVI.—A man, aged 30, on January 25th, 1825, was reported to have fallen down the shaft of a mine to the depth of more than 100 feet, where he was found insensible, with the head downwards. No fracture was visible; the scalp was cut, and the loins bruised. While in this state of concussion and stupor, a vein was opened by a surgeon, but no blood flowed. Afterwards he became affected with vomiting, febrile symptoms, stupor, alternating with delirium.

On the second day he was largely bled (the blood not inflamed); and calomel and antimony were given every six hours, and saline purgatives.

On the 10th day I saw him, affected with vertigo, as if drunk, on assuming the erect posture; delirium, which was worse on movement or noise; respiration slightly stertorous; pulse 96, jarring; he was also very lethargic, but sensible when roused; the pupils contracted during sleep; moveable, but not equally so, on applying the candle to them; on his awaking they became dilated and fixed. It was believed that serous effusion in the brain had taken place, but the prognosis was favourable.

Calomel with antimony was repeated to salivation; a blister on the head; heat to the feet. A diet of gruel; and extreme quiet.

The next two days were passed in heavy sleep, broken by his starting up

in violent delirium; at times, however, he was sensible enough to complain of pain in the temples and in the bowels, which were affected with a mucous purging from the medicines. The pupils were natural.

Calomel continued, the mouth not being affected; and an opiate clyster. Antimonial ointment on the head; a milk diet; and camphor julep, with nitre.

By the 16th day the dysentery was relieved by the opiates; the scalp severely irritated by the ointment; violent nocturnal delirium; at times complaint of the head; instability on assuming the erect posture; pulse 104, tremulous; gums sore by the mercury, which had been taken for five days.

The ointment continued, with a poultice of linseed, and decoction of poppies. Calomel in fewer doses, and laxatives.

The delirium ceased after the poultice, and on the 15th day every symptom had improved, but the pulse was as before.

Mild diet and laxatives.

On the 22d day a still greater amendment; the pulse in the morning became natural, and in the evening he appeared for the first time perfectly to have recovered his consciousness, and he recognized his friends. From this time convalescence was uninterrupted.

SECT. II. ON PARALYTIC AFFECTIONS *without previous Coma, and on protracted Palsy when the apoplectic disposition has passed away.*

The relation of palsy to apoplexy, in a pathological and practical view, is generally admitted. It occurs, however, as a simple and primary affection, even when its origin is within the head; and it may terminate favourably, or pass into apoplexy, on a more powerful application of the exciting causes, or when it has been treated inefficaciously. Some of its symptoms are peculiarly singular and interesting; such as—(a.) The remarkable variations in the state of the pulse, and of the animal temperature of the affected limbs, in connection with an improvement or aggravation of the other symptoms. This feature is seen in Case XIX. and yet more strikingly in a case to be narrated hereafter, among spasmodic affections. (b.) Spasms of the palsied limbs, without any effect on the palsy.

(c.) Habitual tremors of the limbs, without any loss of feeling or of voluntary power, forming the paralysis agitans of writers; of which Case XXIV. is an interesting example. (d.) Thermometric coldness of the affected part, without sensation of coldness; and the converse. (e.) Incessant and severe hiccup, which does not seem to affect the course of the disease. (f.) The tendency of compressed parts to slough. (g.) Various affections of the senses of touch, hearing, and sight, with sometimes long interruption of the sleep, without mental disorder.

Primary palsy, like apoplexy, is sometimes connected with obscure disease in the heart and aorta, and is often the first symptom that rouses the attention of the sufferer to his real state.

It is singular that palsy so seldom arises from chronic epilepsy, although it is sometimes connected with a first attack of acute epilepsy, or transient apoplexy with convulsions.

Palsy, at first simply paraplegic, from an affection of the spinal chord, may pass into hemiplegia with a brain affection.

Chronic cases of weakness of the limbs, appearing to be rheumatic, are sometimes truly paraplegic, and are often mistreated. A sense of girding in the abdominal muscles is sometimes the first symptom in these cases, and should direct attention to the spinal chord.

Simple or primary palsy is generally more hopeful than palsy secondary on apoplexy. Recent cases of hemiplegia are hopeful, although the senses of sight and hearing are affected with illusions, and other evidence is present of an extensive affection of the brain: Case XIX. Recovery from a very decided attack may take place in three weeks, when early treatment is employed: Case XVIII. Instances of a recurrent attack, at an interval of some years, and even where the speech has been affected, may end in recovery. Hemiplegia, however, when connected with disease in the heart, is hopeless. Incomplete paraplegia, with neuralgia of the lower extremities, even when of two years' continuance, is hopeful, when the encephalic and vital functions are unbroken. In paralysis agitans of one year's continuance, com-

plete recovery is not to be expected; but it may admit of great relief. Sloughing of any part subjected to pressure is a bad sign, particularly that painful sloughing of the ball of the great toe; the vital powers then quickly sink.

It is cheering to know that, in apoplectic hemiplegia, with a severe shock to the mind, the intellectual energies may be perfectly recovered, if the constitution be sound, and the habits of the patient good; but this is not of itself an infallible ground of hope regarding the palsy. The state of the palsied limbs as to their nutrition and temperature, and that of the organic function in general, are a better criterion of recovery than the period of time elapsed since the paralytic stroke.

Palsy secondary, on acute epilepsy, the coma being transient, is more hopeful than that following decided apoplexy; and it admits of hope even although the epilepsy has been recurrent and severe, and after disease in other organs; but if proper remedies have been neglected in the first fortnight of the attack, partial palsy may be expected to remain; and, generally, hemiplegia following epilepsy is of bad omen.

Palsy has various origins:—(a) an encephalic origin; in which case it differs only from apoplexy as the lesser from the greater, a part from the whole. Its true cause appears to be pressure on the "figurate brain,"—or the corpora striata, crura cerebri et cerebelli, medulla oblongata, tuber annulare, and the origin of the various nerves of motion and sensation. The notion of a palsy-shock as something distinct from pressure and vascular fulness, is not very intelligible: the only case, as it appears to me, of such a condition, is that from a stroke of lightning so powerful as to destroy life. In any case of a paralytic seizure, however sudden, from ordinary exciting causes, the original proximate cause is pressure connected with sanguineous congestion. The palsy, indeed, does not always disappear as soon as the momentum of the circulation is removed: in some cases the palsy is maintained by a congestion of venous blood in the dilated vessels, and in others it may be referred to a lesion or compression of

the medullary substance, for the restoration of which to its natural state time is required.

An important fact to be known is, that partial palsy, as of the side of the face, or of one hand or one finger, may have, and often has, an encephalic origin, and is liable to pass into apoplexy. In the case of palsy of the facial nerve of the seventh pair, as in Case XXV., it is sometimes difficult to ascertain the origin of the disease: to mistake an encephalic for a local origin would be of serious consequence. Hemiplegia, without coma, or the least affection of the mental powers, sometimes arises from a clot of blood in the hemispheres of the brain.

In a case of headache, hemiplegia, and fatuousness, fatal without coma, there was extensive softening of the walls of the right ventricle, and of the corpus striata and optic thalamus, with much serum in the ventricles. The symptoms had succeeded to erysipelas of the legs.

(b) Palsy has a spinal cord origin. Hemiplegia probably has always an encephalic origin; but more partial palsy, whether of a single muscle, or of the abdominal muscles and pelvic viscera, or of the legs, or of the arms, may have its origin in the several horizontal segments of the cord. Thus I have seen palsy of both arms alone, from disease in the cervical part of the cord; and palsy of the legs also, from disease in its lumbar and sacral portion.

(c) Palsies also arise from disease in the nerves external to the brain and spinal cord, as those noticed by Dr. Cullen, in his "*Class locales; orders, dysæsthesiæ, dyscinesiæ*;" they do not here require a remark, no cases of them being given.

The treatment of palsy.—(a) in its acute state. In the instances of an encephalic origin, the cure for apoplexy is of course adopted; this will generally prevent a subsequent attack of apoplexy, and confine the sphere of the disease, although it may fail to cure it entirely. The cases show that the cure is very protracted, when only bleeding and purging have been employed, and mercury neglected: as likewise, that active purging will be insufficient at an advanced age, when bloodletting is omitted. In the cases from a spinal-chord ori-

gin, cupping, more particularly, is of great service; and, in these cases also, it is scarcely possible to carry purgatives too far; so great is the torpor of the bowels, and so vast the accumulation of feces, that the practitioner scarcely knows when the bowels are really unloaded.

(b) In the chronic state:—this state is not to be judged of merely by the interval of time from the attack; the disease may long subsist in a sub-acute form, or it may quickly pass into a passive state, particularly in a recurrent attack, and may bear stimulant remedies, such as galvanism, strychnia, and hot mineral waters;—when the disease has its origin in the head, to determine the diagnosis of these states requires the severest exercise of judgment. In a case of chronic weakness of the legs, where porter was allowed, the paraplegic affection became hemicplegic, which was much relieved by cupping: the medical attendant afterwards gave brandy and bark, thinking it a case of pure debility, the consequence of which was a second attack of palsy, and which ended fatally. In another case harm was done by tonics in an apparently chronic state of palsy in the face from a cerebral origin.

Strychnia was of singular benefit in a case of palsy of the thighs, with extreme costiveness, from disease in the spinal chord; it seemed greatly to aid the operation of purgatives.

Iodide of potassium, and a mercurial plaster on the sacrum, were also of great utility in a case of long standing, where mineral waters and quinine had been found useless.

CASE XVII.—An elderly woman was affected December 17, 1821, with sudden loss of power of the right side, after a sense of numbness in the part for a short time previously. On the 4th day, speech and deglutition difficult, tongue dry and loaded, pulse 98, jarring.

Purgatives.

5th.—Headache and confusion of thought; articulation improved, after passing a stool.

Leeches to the temple, head shaven and blistered, purgatives repeated.

6th.—The buttocks found to be sloughing; involuntary dejections; headache relieved after purging. 7th.

Appetite and sleep gone; feelings improved.

Calomel and jalap.

Palsy as before; pulse 84, soft. 9th, return of headache; pulse jarring; bowels free; sloughing parts doing well.

Leeches and purgatives.

10th.—Headache; flushing of face; restlessness.

Leeches, purgatives, and an opiate.

11th.—Headache continuing, bowels being costive.

Calomel and jalap, and a clyster.

13th.—Still headache; pulse 72, jarring.

Purgatives and opiates.

15th.—Sleeplessness; pulse 96, harsh.

16th.—Better after purging; slough removed; sores healthy.

17th.—A small tumor discovered over the articulation of the right clavicle with the sternum, pulsating strongly.

To the 21st, little change; then, shivering and delirium; pulse 132.

Wine and opium, and purgatives.

22d.—Sores more sloughy; pulse 156, irregular: death, the next day. The palsied side became quickly cold after death; the other side retained its heat!

Inspection.—A clot of blood in the left hemisphere, near the corpus callosum. The arteries rising out of the chest much dilated and curved.

CASE XVIII.—A man of middle age, formerly intemperate, latterly sober, on November 21st, 1821, was suddenly attacked with headache and palsy of the right side, succeeded by vomiting on taking medicine, and more acute headache, which continued to the 24th, and was then attended with incoherence and confusion of thought.

Bleeding to 24 ounces; head shaven and blistered; purgative medicine and clysters.

The 4th day, pulse 66; tongue white; two stools only.

Calomel 15 grains; clysters and salts.

5th.—Urine that was passed in bed now passed naturally; purgatives ineffectual.

Jalap, with calomel, and clysters.

6th.—Less palsy of the arm, the bowels being freely purged.

7th.—Headache, but mind more collected; right leg still palsied; pulse 88, full.

Leeches to the temples.

9th.—Palsy lessening, but headache remaining. In the next eight days, a gradual amendment from mild purgatives; meat then allowed, which was followed by severe headache, for five nights preventing sleep; pulse 104.

Purgatives, and cold washing of the head.

25th.—Convalescence advancing, but the right eye and cheek œdematous.

CASE XIX.—A man of a full habit, 65 years of age, affected with hemiplegia of the right limbs, loss of feeling and of muscular power of the right cheek, and of the muscles of the tongue, which was turned to the right side, but its feeling unimpaired; black spots before the eyes. The illness was of recent origin; ascribed to exposure to cold.

Bleeding: the blood sily; purgatives.

January 29th, 1820.—No headache; the palsied side feels cold to himself, and is sensibly colder, and the pulse of the palsied arm is much weaker than in the sound!

Cold washing of the head, and purgatives.

30th.—Headache all night, with the cold washing; bowels purged, and the muscular power of the tongue and limbs much improved; pulse 80, full, feeling better on the head being elevated in bed.

Leeches and purgatives.

31st.—More heat in the palsied arm after purging; black spots seen before the eyes. Then an improvement to February 7th, while taking antimonial powder, but the disordered vision continued.

Purgatives and cold washings resumed, and 10 grains of antimony every night; 4 drachms of mustard-seed every day.

These medicines were continued, (the antimony induced strong purging) with a liniment of turpentine and ammonia to the limbs, and by the 20th he was convalescent, after three weeks of treatment.

CASE XX.—A woman, 35 years of age, after severe exposure to cold, got amenorrhœa, which was succeeded by pain in the legs, and loss of muscular

power, but not complete palsy: these symptoms continued for 9 months, to July 1832, when she took sarsaparilla and nitric acid, for weakness and perspirations; a blister was put on the sacrum, and camphor liniment on the legs. In the course of three weeks she was so much improved as to walk out of doors: then a bowel complaint came on, which was relieved by calomel and magnesia; and after this, the mineral acid was resumed with benefit. In the last week of February, however, after drinking porter to excess, vertigo came on, succeeded by an extreme sense of coldness on the head, loss of speech, and palsy of the right limbs. Cupping in the loins, blisters, alteratives, and aperients, made a great amendment in the course of three weeks, and then change of air was recommended. At the end of April, I saw her again, nearly dead, after having taken brandy and bark, which had induced excessive purging and general drowsy. At the middle of May, another paralytic seizure ended fatally.

CASE XXI.—A young man of studious habits, in November 1828, after exposure to cold, was attacked with palsy of the right cheek, and pain in the seat of the portio dura of the seventh nerve.

January 9th, 1829.—No head complaint.

A blister behind the ears.

15th.—The same state.

Mercurial antimonial ointment on the cheek, and alterative medicines.

Feb. 2d.—Some headache and low spirits; right side of the face swollen; the left nostril retracted, the right sunken; loss of feeling in the inside of the right cheek; mouth drawn to the left side, and more so on shutting the lips; costiveness, and a small pulse.

Oil of turpentine and castor oil every morning; extract of gentian and ammoniated copper; meat diet, exercise, and electricity.

March 2d.—Palsy the same; headache and sleeplessness; bowels slow, strength improved.

Purgatives.

20th.—More retraction of the left cheek, and confusion in the head.

Cupping to 10 ounces, and mercurial purgatives; antimonial ointment on the scalp.

22d.—Great relief of the head; cheek less retracted.

Leeches and purgatives.

In April, he continued gentle purgatives and leeches, and at the end of the month the palsy was much relieved, and he felt well.

[To be continued.]

SURGICAL CASES

OCCURRING IN THE

ST. MARYLEBONE INFIRMARY,

Treated by

R. A. STAFFORD, Esq. F.R.C.S. &c.

Surgeon to the Institution.

(For the London Medical Gazette.)

CASE I.—*An external opening between the first and second ribs of the left side, communicating with a cavity in the left lung.*

July 25th, 1844.—Thomas Butler, æt. 27, had long been the subject of phthisis. He expectorated purulent matter, and several cavities, by stethoscopic examination, existed in both lungs. About six or eight months previous to his admission into the Infirmary, ulcers formed on his neck and chest. Those on the neck were situated immediately above the clavicle, and ulcerated very deeply behind that bone. On the left side there was an ulcer between the first and second rib, about an inch in circumference, and very deep, communicating with the lung. Air was both inspired and expired through it; inasmuch that if lint, or any other application, were placed upon the opening, it could be drawn inwards or blown off according to the inspiration and expiration. If the flame of a candle, also, was placed opposite to the aperture, it could be nearly blown out, and the air could be distinctly heard rushing from the lung. The patient, however, did not like the wound to be open, and expressed that it distressed him if it were exposed to the air too long. It was therefore always kept closed and protected, and the external atmosphere was never admitted, excepting when the wound was dressed. The sores discharged very profusely, and the poor fellow was in the lowest condition.

It could hardly be expected that recovery could take place with such

extensive disease of both lungs: consequently, the patient was supported and nourished, and those medicines were prescribed which palliated the disease, and made the way easy to the grave.

Post-mortem.—There was an oval ulcer in the neck three-fourths of an inch in depth, immediately above the clavicle, and also another of the same description. The ulcer between the first and second rib on the left side was connected with a phthisical cavity in the upper portion or apex of the left lung. Both lungs were extensively diseased. The dissection was made by Dr. Boyd, who has been so kind as to favour me with an account of it, and he informs me that both of the ulcers, that above the clavicle and that between the first and second rib, communicated with the œsophagus.

This case is extremely interesting, and more particularly at the present time, since Dr. Hastings and Mr. Storks perforated an excavation of the left lung. It would appear that nature herself pointed out the mode of relief in some cases. This man lived for several months with a cavity in the left lung, connecting it by an opening in the left side with the external atmosphere. He died from extensive disease of both lungs, nor did it appear that the communication of the cavity with the air at all accelerated his death; for although he did not like the wound to be exposed for any length of time, yet he never had any objection to gratify the curiosity of those who wished to see it.

Besides the case I have just related, I have seen two others where external openings were connected with the cavity of the pleura. One occurred not a year ago, and was owing to caries of the second rib on the right side. In this the cavity of the pleura was full of water, and it could be sponged out through the external opening. The other case was much of the same description, and arose from disease of the fourth or fifth rib on the right side.

CASE II.—*Case of a diseased ankle-joint.—Amputation.*

W. Stabback, æt. 40, of a strumous diathesis, was admitted into the St. Marylebone Infirmary, with a diseased ankle.

It first began with pain in the joint,

which afterwards became swollen, and apparently contained synovia. Leeches were frequently applied, and afterwards blisters, but with little benefit. Abscesses formed, and discharged pus, leaving sinuses behind, which were connected with the joint, and a probe could be passed into it. More sinuses formed, all of which ran into the cavity of the joint. Poultices, &c. were applied. The man got worse, but he declined losing his leg. He was supported by nourishment, but no remedies were of the least use; his health began to suffer. It was represented to him that if he did not consent to amputation he would die; he still declined the operation. He got worse and worse, being hectic, and becoming extremely emaciated; he now himself began to see his condition, and of his own accord requested that the limb might be taken off. For three or four days before the operation was performed, he was supported by nutritious diet—wine, porter, eggs, &c., but it was feared incipient phthisis might exist.

The operation was performed in the presence of Dr. Harrison, Dr. Boyd, and other medical officers of the staff, Mr. Avery, surgeon of the Charing-Cross Hospital, Mr. Markham, &c. The circular incision was preferred, as being the safest in this case. The limb was removed in about three minutes. The man was taken to bed, and an opiate administered. The stump went on well. No fever of any consequence supervened. On the third day slight erysipelas appeared on the stump, but which disappeared in two or three days. He was ordered a generous diet—wine four ounces, beef-tea, strong gravy, one chop, and three eggs daily. His pulse, which had been reduced to the lowest ebb before, now increased in strength, but still was very feeble. He took the Mist. Cinchon. Arom. every six hours, and an anodyne at night. The stump began to suppurate, and discharge freely. All went on well; the ligatures came away; at present the wound is nearly healed; and the patient is much improved in health.

On making a section of the ankle-joint, it was found that three or four sinuses ran into the capsular ligament. The synovial membrane covering the cartilage was partly absorbed, and on the surface of the cartilage of the joint

itself considerable ulceration existed. There was ulceration in the bone between it and the cartilage, and the cellular structure of the former was softer than natural.

CASE III.—*Disease of the Sternum.*

Thomas Lovesey, æt. 55, was admitted into the Infirmary, Nov. 19, 1844. About two years ago, he suffered great pain in the chest, having a cough at the same time, and also expectoration. He first felt pain in the sternum about eighteen months ago. Swellings appeared, which became inflamed, and broke and discharged matter. More abscesses formed, from some of which there was a considerable discharge of blood. At this time there are about fourteen cicatrices, and four or five wounds open. They appear to be connected with the bone and cartilage of the sternum itself, as these structures can be readily felt at the bottom of the sore by a probe. The treatment has been at first poultices, since which, as the sores were evidently of a strumous character, a lotion of iodine has been constantly applied by dipping lint into the solution, and laying it over the sore.

℞ Iodinii, gr. j. ; Pot. Iod. gr. ij. ; Aq. Pluv. ℥iv. M. ft. Lotio.

The constitutional treatment has been bark, quinine, and other tonics, combined with generous diet. Under this treatment all the sores healed, but the lungs, though quiet, are still diseased.

That there is a sympathy between internal and external parts there can be but little doubt, and this case particularly exemplifies it. It would seem that nature herself threw out her own counter-irritation.

[To be continued.]

STRUCTURE OF THE CORPUS LUTEUM.

To the Editor of the Medical Gazette.

SIR,

A PAPER was published by me, on early corpora lutea, in the September number of the *Edinburgh Medical and Surgical Journal*. In it I noticed a case which had given rise to some discussion between Dr. Robert Lee, of London, and myself; and I there published

the correspondence which had taken place.

In your journal for November 8, 1844, Dr. Lee has published a reply, containing statements controverting what I had then said, and calculated to throw doubt on the accuracy of my remarks. I therefore have to request you, as a simple act of justice, to admit the following explanation into the pages of your valuable journal.

The chief ground of complaint which Dr. Lee seems to urge, and to continue to repeat, is, that I have either suppressed one letter from him, or not published correct copies of those letters which he sent to Dr. Bowman and myself. All the letters that were received either by Dr. Bowman or myself were published in the 161st number of the *Edinburgh Medical Journal*, with two exceptions; these, however, I now subjoin, and also the accompanying document from Dr. Craigie, the respected Editor of the *Edinburgh Medical and Surgical Journal*, to shew how far the letters I formerly published, and the copies of the two now published, accord with the originals.

Edinburgh, 22d January, 1845.

I have examined the originals of all the letters which were addressed by Dr. Lee to Dr. Bowman and Dr. Paterson, on the subject of the corpus luteum submitted by Dr. Bowman, in May 1844, to Dr. Lee for examination, and which letters, excepting two to be afterwards specified, were published in the 161st or October number of the *Edinburgh Medical and Surgical Journal*; and the following I find to be the result.

The letters are eight in number; seven written on 8vo.-sized post note paper, and one on ordinary-sized post paper.

They bear the following dates:—

1. 13th May, to Dr. Bowman; the same as No. 2, published in page 468, No. 161, *Edinburgh Medical and Surgical Journal*.

2. 22d May, 1844, to Dr. Bowman; No. 3, of page 468, No. 161, *Edinburgh Medical and Surgical Journal*.

3. 26th June, 1844, to Dr. Bowman; No. 4, of page 469, No. 161.

4. 30th July, 1844, to Dr. Paterson; No. 6, of page 470, No. 161.

5. 5th August, 1844, to Dr. Paterson; No. 8, of page 471, No. 161.

6. 6th August, 1844, to Dr. Bowman; not published in the Medical and Surgical Journal.

7. 12th August, 1844, to Dr. Paterson; No. 11, at page 471, No. 161.

8. The letter on ordinary-sized post paper, dated 30th July, 1844, addressed to Dr. Bowman; not published in the Medical and Surgical Journal.

All these letters are distinctly in the hand-writing of Dr. Lee. All of them published correspond *verbatim* with the copies published in the 161st number of the Journal, except the two following circumstances in the letter of the 26th of June, 1844. In the original, instead of "important business," the expression is "unexpected business." But the word "unexpected" is written so indistinctly, that it might be read hastily "important."

In the same letter, at the end, the expression is very truly yours, instead of yours very truly.

There is no letter of date between the 13th of May, 1844, and the 22d of May, 1844.

A letter marked No. 9, from Dr. Paterson, and published in the 161st number of the Edinburgh Medical and Surgical Journal, p. 471, with the date 9th of August, 1844, has been made the subject of complaint by Dr. Lee, who states, that he never received that letter, but received one of the 10th of August, differing certainly in several modes of expression*. Both letters have been since published in the MEDICAL GAZETTE, November 1844, No. 5, vol. xxxv. p. 158. The facts and statements in both letters appear to me to be substantially the same. At all events any reader may compare them and form his own judgment.

Of the two letters, dated 30th July and 6th August, not hitherto published, the following are exact copies.

DAVID CRAIGIE.

London, 4, Saville Row,
30th July, 1844.

MY DEAR SIR,

WILL you have the kindness to send me at your earliest convenience the two letters which I wrote to you stating the grounds from which I was led to conclude that it was a true corpus luteum which was forwarded to me for exami-

nation. It appears from a letter received this morning from Dr. Paterson, that it is the corpus luteum which he had figured and described, and from which, and the history of the patient, I had expressed my conviction that it was a false corpus luteum—in fact, nothing but a clot of blood. On first examining the preparation you sent me, I formed the same opinion, and expressed it in the most decisive manner to Mr. Jones: placing, however, much more dependence on his judgment than my own, I was induced to alter my opinion, and coincide with him. If I receive copies of my letters to you, I shall publish the whole statement in the Medical Gazette next week.

I remain,

My dear Sir,

Very sincerely yours,

(Signed) ROBT. LEE.

Dr. Bowman.

4, Saville Row,
6th August, 1844.

MY DEAR SIR,

WILL you have the goodness to inform me by return of post whether or not you received a letter from me respecting the preparation of the corpus luteum, between the 13th and the 22d of May.

I remain, very sincerely,

(Signed) ROBT. LEE.

Dr. Bowman.

Certified to correspond with the originals.

D. CRAIGIE.

22d January, 1845.

It is necessary for me to add a few words regarding the letter of the 13th May, about which Dr. Lee has said so much. Dr. Lee states that no copy of it was sent him. Its date, however, was forwarded to him, and the general tenor of its contents, as well as the fact that it contained no opinion on the preparation. Dr. Lee, possessed of this information, still writes for a letter between the 13th and 22d May, a letter which had no existence. He now, however, says that it was the letter of the 13th May that he all along wanted. To my mind it appears that had Dr. Lee wanted a copy of his letter of the 13th May (with the date and tenor of which he had already been furnished), he would have written for it, but instead he asks for one between the 13th and 22d May, and yet now says that it was the letter of the 13th that he re-

* The letter here referred to was published from a scroll copy, which had been preserved, and without the alterations being noted, which were made in the letter, as sent to Dr. Lee.—R. P.

ferred to. Such conduct appears to me inexplicable, and I leave the reader to draw his own inferences regarding it.

I may state once for all, in reply to various charges which Dr. Lee makes in the communication referred to, that Dr. Bowman, who sent the preparation to him, knew nothing whatever of its history, until after Dr. Lee's opinion on it was delivered, and that the preparation itself was taken out of a preparation jar, where it had been preserved in spirits, wrapped up in clean linen rags steeped in spirits, and put into a tin cannister to enable it to be sent through the post. In this way it must have reached Dr. Lee, for it was never even opened at Monkwearmouth.

Before concluding these short remarks, however, I feel that I owe a statement, by way of apology, to my professional brethren for the means which I adopted to procure the delivery of a candid opinion on the preparation in dispute, from Dr. Lee. For the following reasons I considered myself justified in having recourse to a plan with Dr. Lee that I never would have had recourse to with any other member of the profession; for, 1st, I knew that in 1832 Dr. Lee published in the *Philosophical Transactions* an account of an examination of six gravid uteri and many placentæ, from which he came to the conclusion, "that a cellular tissue does not exist in the placenta, and that there is no communication between this organ and the uterus by means of great arteries and veins;" thus attempting to set aside the well-known opinion of the Hunters. From Dr. Lee's own confession, it appears that he found out his error twelve months afterwards, yet it was not till 1843, or nearly ten years after he was convinced of his error, that he made such known to the profession; during this long interval he allowed anatomists and obstetricians to dispute about the truth of his supposed discovery, while all the time he was already convinced in his own mind that the views he had published were erroneous.

So late even as 1843, we find Dr. Churchill, of Dublin, in his work on Midwifery, using the following sentence: "Lauth, Velpeau, Liller, Coste, Radford, Ramsbotham, Millard, Noble, &c. agree with Dr. Robert Lee." I accuse Dr. Lee, in the name of the whole profession, of wilfully misleading

them on this point. It is of no avail to argue that he stated his change of opinion in 1833, in a review of Velpeau's *Embryology*, in the *MEDICAL GAZETTE*; for the editor stated, in his number for June 21st, 1834, "that Dr. Robert Lee is still pursuing his inquiries on the subject," and adds, "we have not learned that there has been any change of opinion." Mr. Noble, too, repeats with apparent authority the same statement.

2dly, I knew that Dr. Lee, in a correspondence published by him in the *Lancet* of 20th April last, allowed to be appropriated to himself as his own the theory of menstruation of Dr. John Power, and at the same time thus claimed the illustration of that theory which had been privately made to him by Dr. Girdwood, of London.

And 3dly, That in a letter signed Scrutator (and which, with various other anonymous attacks in the *MEDICAL GAZETTE*, most men attribute to Dr. Lee), statements are made which Professor Reid, of St. Andrews, has characterised in the same journal as being "a glaring attempt to pervert the truth."

I confess I have all along regarded the point in dispute between Dr. Lee and myself as of considerable importance; and the means which I used to gain his candid opinion were adopted from my not seeing any other way in which this object could be obtained. Dr. Lee has thus *first* violated his written promise by not publishing a confession of his error in the pages of the *MEDICAL GAZETTE*; and *secondly*, he has publicly recanted an opinion given privately, and under the most unbiassed circumstances.

Having offered these remarks, I leave it to the profession to determine how far the language used by Dr. Lee in his last letters in the *GAZETTE* is justifiable. I shall take no further notice of any communication from Dr. Lee, whether he chooses to attach to it his own name or any anonymous title.

I am, sir,

Your obedient servant,
ROBERT PATERSON, M.D.

Leith, Jan. 24, 1845.

[Here this controversy must terminate.—*Ed. Gaz.*]

SOME OBSERVATIONS
ON THE
MEDICAL TOPOGRAPHY, CLIMATE,
AND DISEASES, OF THE BIGHTS
OF BENIN AND BIAFRA,

WEST COAST OF AFRICA.

By W. F. DANIELL,

Member of the Royal College of Surgeons of
England, &c.

[Continued from p. 586.]

IN most of these countries, live stock, game, &c. may be purchased at comparatively trifling prices, while the greater number of the edible fruits and vegetables that abound in the West Indies and tropical America can be procured without the slightest difficulty. To enumerate the whole would occupy too much space; a reference, therefore, to the most conspicuous productions of one place will serve as a guide for others, since the majority are more or less distributed throughout the other regions of central Africa. With the plants common to the Slave Coast may be included the *Zingiber officinale* (ginger), *Sarcocephalus esculentus* (cotton peach), *Gossypium herbaceum* (cotton plant), *Tamarindus Indica* (tamarinds), *Cucurbita Citrullus* * (water-melon), *C. Melopepo* (squash), *Annona Muricata* (soursop), *Ricinus Africanus* (African Palma Christi), *Chrysophyllum Cainito* (star-apple), *Holcus spicata* (kous-kous), *Jatropha Janipha* (sweet cassava), &c. The *Gossypium arboreum* (cotton-shrub) fur-

nishes the raw material from which the celebrated Jaboo cloths are manufactured. These fabrics surpass the British cotton goods in strength and firmness of texture, but are inferior to them in fineness of execution. The *Zea Mays* (maize) is grown in immense quantities, and is used not only as an article of food, but also of commerce. The *Allium Ascalonicum*, *Brassica Oleracea*, with a few other culinary vegetables, were originally imported from the Cape de Verd Isles and Europe, and have now become naturalized, and are largely cultivated in the gardens of the natives.

The Rio Formosa is better known under its common appellation of Benin River. It commences the series of navigable streams more intimately connected with the Niger, and was, during the last two centuries, a famous mart for the purchase and exportation of slaves. It is now but rarely frequented for such purposes, a more legitimate trade, which had been irregularly carried on shortly after its first discovery, having superseded this traffic in the human species. If we can credit Di Barros, it was either this or the Bonny River which was explored by Alfonso de Aveiro in 1485, in consequence of the king of the country requesting to be instructed in the Christian religion: he also states that an embassy was sent many leagues into the interior to a monarch of the name of Ogane, to whom the kingdom of Benin was at that period tributary. In Hackluyt's Collection of Voyages there is a very quaint and curious description of Benin River, from which we may glean much useful information. It appears that Capt. Wyndham visited it so early as 1553, in company with a Portuguese trader named Antonio Anes Pinteado, for Mallagetta pepper, and from this voyage may therefore be dated the commencement of the English commerce. In 1588, a Capt. Walshe was trading here, and again in 1590; in both these voyages he lost the greater number of his men, but fully freighted his ship with Jaboo cloths, oil, pepper, and ivory. At present very little trade is carried on with the natives, three or four British vessels alone monopolizing its exports, which consist chiefly of palm-oil and ivory.

The term Rio Formosa is of Portu-

* The *C. Citrullus* is highly esteemed by the inhabitants of several African countries for its antiseptic, refrigerant, and antifebrile properties. It may be found in nearly all the cultivated districts on this and the Gold Coast. By the Arabs it is named *Bateekh zieh*, and by the Egyptian Arabs *Barteeck*. It is frequently alluded to in conjunction with other plants belonging to the *Cucurbitaceæ*, in the writings of the Arabian physicians. Rhazes, in a work entitled "*Kitab fil jadrie wal husbab*," &c., says that "*Aqua etiam cucurbitæ et aqua peponis Indi, et aqua cucumeris angurini et mucilago seminum psyllii et his similia*," &c. were remedies advantageously administered in the different stages of both small-pox and measles. Avicenna, in his well-known "*Canon fil tibb*" (Canons of Medicine), mentions several species of *Cucurbita* under the names of *Batiech*, *Batheca*, *Charha*, &c. and recommends preparations of them in various maladies. In Egypt, and other parts of northern Africa, it is resorted to by the common people as a medicine in ardent fevers. "For this purpose they have a variety that is softer and more juicy than the common sort; when this is very ripe, or almost putrid, they collect the juice, and mix with it rose-water and a little sugar."—Loud. Cyclop. of Agric. p. 809.

guesse origin, and signifies in that language, a beautiful river. It has, however, been employed more to characterise the bold and open expanse of water, than any picturesque scenery, unless the wild and desolate forests that fringe its banks be dignified by its assumption. At its junction with the ocean this river is one mile and three quarters in breadth, but as it recedes towards the interior, proportionably diminishes in size, and at Youngtown, a village distant from fifteen to twenty miles from its mouth, divides into three terminal branches, the first leading to Gatto, a small trading port in the kingdom of Benin, the second, a continuation of the main trunk penetrating beyond the Subo country, and taking its source in the mountainous districts northwest of the Quorra, and the third, or last, termed the Warrée or Youngtown creek, that joins the Quorra, a few miles below the town of Ebue.

Northwest head, an extreme projection of the land at the entrance of the river, is situated in $5^{\circ} 46' \text{ N. Lat.}$ and $5^{\circ} 4' \text{ E. Long.}$ Like Cape St. Mary in the Gambia, it may be stated to be the most healthy spot in the river, being fully exposed to the daily sea breeze, and less affected by those pestiferous south-east winds so detrimental to all Europeans who visit here. From this point, a bar of heavy mud and sand extends to Salt-town, on the opposite side, partially obstructing its entrance, and on which, in the rainy season, a tremendous sea breaks with a resonance distinctly audible for several miles inland. A small village named Georges-town is located on this promontory, in close proximity to which may be distinguished many graceful trees, intermingled with the sombre foliage of the mangrove bushes; the most prominent are the *Elais Guineensis* (palm oil tree), *Cocos nucifera* (cocoa nut), *Musa sapientum* (plantain), *Sagus vinifera* (wine palm), *Psidium pyrifera* (guava), &c. A narrow sandy beach, with a substratum of hard black clay, stretches from this place to Fish-town, about a mile up the river. The shore from this place to Jacqua creek is composed principally of alluvial deposits, covered by dwarf mangroves, that project so far into the stream as to conceal its banks; and this is the common appearance throughout the river, except in those localities inhabited by

the natives. At the aperture of the above creek two English factories are erected, in each of which a few white artificers and Kroomen reside, under the superintendence of a head factor. These edifices are commodiously built of wood, somewhat after the Spanish style, and contain a number of apartments on a middle story, elevated above the adjoining swamps. They are five miles distant from the bar.

Jacqua, or Waccos, is the largest town in the kingdom of Warrée. It is erected on the right bank of a narrow tortuous stream, in a low and impenetrable morass, two miles from the river. The population amounts to near four thousand. The diseases to which the inhabitants of this part of the river are subject originate more from the humid and confined atmosphere of the locality in which they live, than from any other cause: their type is usually asthenic, but it is greatly modified by change of seasons, and the prevalence of rains. Syphilis is perhaps the most frequent and fatal of those maladies to which the male inhabitants are liable, and predominates more among them than among the females. Many are cut off very early in life from want of the necessary remedial applications, and it is not uncommon to meet with cases which have continued during nearly two-thirds of the patient's existence. The worst forms of syphilitic disease which have come under my notice, have been the foul and malignant phagedenic ulcers, that indiscriminately attack both sexes. Gonorrhœa virulenta, nodes, cutaneous eruptions, and, indeed, all the sequelæ of syphilis in multiform varieties, are extremely prevalent, and not unfrequently resist the most energetic and judicious treatment of the European surgeon. In the native cure of such affections, superstition exercises her delusive sway; charms, amulets, with other fetish remedies, are employed *ad libitum* by designing priests, whose useless mummeries are calculated to afford but a transitory hope of any other than a fatal termination. The dracunculus, or Guinea worm, is but rarely seen in this part of Africa, being restricted more to the natives of the interior, and the Gold and Windward coasts. Two cases only came under my care in Jacqua-town, in one of which I had an opportunity of witnessing a country operation for the extir-

pation of these vermicular parasites. A small semilunar incision was first made in the skin of the forearm, to expose the extremity of the worm, and moderate pressure used to facilitate its protrusion; it was then seized, and cautiously drawn forth to the extent of one or two inches. Two ligatures, constructed from the exsiccated fibres of some gramineous plant, were next applied to that portion of the worm nearest the orifice in the skin, the other part being nipped off; the extremities of both of these ligatures were of sufficient length to encircle the limb, round which they were fastened. A young plaintain leaf, smeared over with palm oil, was then placed over the wound, and friction carefully employed with the same oleaginous fluid on the skin, along the course of the worm. This process was daily performed, and a small portion of the worm regularly exposed, until the whole was gradually withdrawn; a perfect cure being the result.

On the environs of Jacqua are several enclosures for the cultivation of the *Dioscorea bulbifera* (yam), *Hibiscus esculentus* (ochro), &c. The *Citrus lim.* (lime), *Jatropha manihot** (bitter cassava), *Capsicum annuum* (common pepper), *Musa paradisiaca* (banana), &c. and several huge trees belonging to the *Mulvaceæ*, occasionally intersprinkled with the *Pandanus candelabrum* (chandelier tree), may be observed amid the mass of human habitations that line both sides of one long avenue or street, which in the rainy season is partly inundated with water. Throughout these swampy regions an apparently ceaseless growth of the *Rhizophora mangle*

(common mangrove), effectually conceals most objects that exist in their immediate vicinity. They constitute two-thirds of the vast forests that clothe the maritime lowlands of equatorial Africa.

The same low and unhealthy tract of country, with two or three intersecting creeks, extends for some distance beyond Reggio, an insignificant village attached to the kingdom of Benin. It is situated on a central point of land at the confluence of the Gatto creek with the river. The intrepid traveller, Belzoni, to whom we are so much indebted for the interesting researches into the antiquities of Egypt and northern Africa, expired at Agatto from an attack of dysentery, after an abortive attempt to penetrate into the Hausa country. His solitary grave on the outskirts of the town may still be seen; an elevated mound of earth, overrun with weeds, with the fragment of a decayed wooden cross, are the only traces that now indicate the spot. Above Reggio the continuation of Benin river bends east-north-east, and about forty miles from the sea bifurcates into two branches, both of which were first explored by the enterprising Mr. Becroft in 1840, who has satisfactorily proved that they had no communication with the river Quorra, as had been previously supposed.

The Subo country consists of an extensive series of fertile plains, thirty miles above Reggio, beautifully ornamented with park-like clumps of trees, and verdure of the freshest tint. The plantations of the natives for the production of yams, plaintains, cassava, &c. occupy the inferior districts, and enjoy a high reputation for salubrity, inasmuch as most invalids resort there in all protracted cases of sickness, and generally with most favourable results. From the purity of the water of the river as it flows through these regions, it has been selected to provide for the wants of the homeward-bound vessels, which are often in the greatest difficulties from a deficiency in this necessary article.

[To be continued.]

* From this plant is prepared manioc or mandioca, an article of food constantly used on board the merchant vessels for the feeding of live stock. The natives designate this preparation by the word *Farina*, originally introduced by the early Portuguese traders, and derived from the Brazilian term *Farinha de pau*, or meal of wood. In Benin and Warri, when any great dearth of vegetable food prevailed, it was given to the slaves, and is now occasionally consumed by them. Europeans ought to avoid partaking of it in any form, since it is apt to create, even when taken in small quantities, colic, diarrhoea, and other distressing symptoms, and finally brings on dysentery. Formerly, when any difficulty existed in obtaining provisions for the slave ships, farina, from its abundance, was employed as a substitute for the support of their human cargoes. From its being very hastily and imperfectly made, the consequence was, that, before two-thirds of the voyage had been completed, nearly one-half of the wretched beings confined in these floating prisons perished from dysentery, and other enteric affections.

ON THE USE OF SULPHATE OF MANGANESE IN VARIOUS DISEASES.

By R. H. GOOLDEN, M.D.

Fellow of the Royal College of Surgeons, Physician to H.M.S. Dreadnought, and Assistant Physician to St. Thomas's Hospital.

(For the *London Medical Gazette*.)

AN article published in the *MEDICAL GAZETTE*, Nov. 8th, of the past year, entitled "Researches on Gout," by a gentleman eminently celebrated for his knowledge of chemistry, and his application of that knowledge to pathology and therapeutics (Mr. Alexander Ure), called my attention to the use of the sulphate of manganese. This salt has given some marked results affecting the biliary secretions in a remarkable degree. Under the impression that it may make a useful addition to our Pharmacopœia, I have been induced to offer you the results of my experience in its use, claiming no further merit in its introduction than an honest desire to test the truth of Mr. Ure's suggestion by such experience as has been afforded me. When taken upon an empty stomach, in doses of one or two drachms, it has invariably produced vomiting in less than three hours, and generally within an hour; and the matter vomited has consisted of a very large quantity of yellow bile. After a meal, the same effect has taken place, but not invariably.

It very rarely acts as a purgative alone, and after it has been exhibited for several days, I have often been obliged to have recourse to other purgative medicines, in consequence of the want of action of the bowel. After the first dose it seldom acts as an emetic. The appetite has invariably increased during its exhibition, and when the first emetic effect has subsided the patient is free from all uneasy sensations, and expresses himself as feeling lighter and easier than before.

It sometimes leaves a bitter taste in the mouth, which is all that is complained of until the patient vomits.

The stools, which are sometimes dark coloured, soon become yellow and loaded with healthy bile; but if its use be continued for four or five days, they become lighter, and at length shew a total absence of bile, appearing like

jaundiced stools of the colour of parchment, but there is no jaundice either in the skin or urine.

If the medicine be discontinued, the yellow colour of the stools returns.

In one case which was admitted into the Dreadnought with jaundice, and which subsequently died from inflammation of the spleen, with tubercular deposit in that organ, the jaundice very much subsided under the use of the medicine. The liver was healthy, but paler than natural; the gall-bladder quite empty, and the spleen very much enlarged, softened, and loaded with huge masses of tubercles.

I have subjoined a few of the Cases illustrative of the action of the medicine, selecting only those portions of them which have immediate reference to the use of the sulphate of manganese.

George Ashlee, æt. 34, admitted for periosteal pains, with large nodes on the shin bones, elbows, and frontal bone: treated with Iodide of Potassa and Opium. He had taken large quantities of mercury in the West Indies for disease of the liver.

After taking his medicine for fourteen days, he lost all his pains, with the exception of the right shoulder, which was so severe that he could hardly move his arm; there was much tenderness at the acromion process; he was blistered, and had an issue, which did not appear in any degree to lessen this pain.

January 6, 1844.—Under the idea that the pain was connected with the liver, he was

Ordered—5ij. of Manganisæ Sulphas in Oss. of water in the morning.

He vomited a quantity of pure bile an hour afterwards, and the pain in the shoulder completely left him.

A lady had been under my professional care at various times, since January 1841. Her sufferings were in connection with derangements of the liver and bowels.

When not taking medicine, the bowels were confined, and the evacuations dark coloured and scybalous. She was seized at various intervals with excruciating pains, like the paroxysms of gall-stones. No gall-stone has ever been seen, although carefully searched for. She has been severely jaundiced four times, and this has always hap-

pened after taking some form of opium, or other narcotic, which I have found it necessary to avoid unless the paroxysms have been unusually severe, as her recovery was always protracted by opiates in consequence of their affecting the functions of the liver.

These paroxysms are often preceded by a slight yellowness about the eyes and face, flatulence and loss of appetite, nausea, headache, a sense of weight or burning in the right hypochondrium, and with pain or numbness in the right arm.

Since her illness she has become very thin, although in that respect much improving for the last six months, and for the same period has suffered much fewer attacks of spasm. I should mention, that she has occasionally had severe rheumatic pains in the muscles of the chest and abdomen, attended with considerable lithate of ammonia deposit in the urine. The lithic acid diathesis is constitutional. The treatment which has been adopted has been to keep the bowels open, changing the aperient from time to time—*Infus. Sennæ*, with *Magnes. Sulph.*; *Pulna water*; small repeated doses of sulphate of soda or magnesia, compound decoction of aloes, or pills of the watery extract of aloes (*Copeland's Aloetic Pill*), and occasional doses of calomel and blue pill, which were sometimes repeated for several times, until the bilious colour in the stools was produced. The nitromuriatic acid, both as a wash, and given in mixture, with various bitter tonics; but the only bitter that did not derange the stomach was salicine. The *vinum colchici* was used at various times with marked benefit, given in the solution of bicarb. of magnesia. She was generally very tolerant of this medicine, but on one occasion it produced some inflammatory state of the bowel, that made me very unwilling to recur to its use, for the smallest quantity of laudanum always produced obstruction in the liver.

In November she had a very severe return of the paroxysm, which lasted for eight hours, and the following day a recurrence, which continued twelve hours. No opiate was given, but carbonate of soda dissolved in a large quantity of warm water, on account of the vomiting, which it generally allayed, and warm fomentations to the stomach.

After the subsidence of the second

attack, the bowels remained constipated, and several doses of five grains of calomel, followed by sulphate of magnesia and senna, and the *Pulna water*, brought away a quantity of scybala, and kept the bowels freely open; but the stools were very dark-coloured and loose, and she began to suffer severely from the prolapsus, which induced me to discontinue the use of purgatives for a time, and she was very feeble and depressed, and complained of burning sensations in the right hypochondrium. After several days I ordered—

5j. of *Manganesiæ Sulph.* in ℥iv. of water to be taken in the morning.

In about half an hour afterwards she vomited Oj. of pure yellow bile, and during the day had three copious motions, the last two of which were quite yellow. I saw her in the evening, when she said that all her uneasiness had left her, she felt in good spirits, and had a good appetite. The manganese was repeated in smaller doses of ʒss. twice a week for a few weeks; no sickness followed. She left town for the sea side, and has had no return of her bilious attacks since, and is considered by herself and friends to be in good health.

We must not here attribute too much to the effects of the sulphate of manganese, as the patient had been improving in health for some time previously; but the immediate effects of the drug were clearly marked, in producing the copious flow of bile, which calomel had failed to do, and it is to be observed that no mercurial had been given for three days previous to the dose of manganese.

Edward Day, æt. 24, admitted November 16th, with icterus of two weeks' standing.

Nov. 20th.—Not much general indisposition; improved since admission. Some tenderness under the ribs on the right side. Nausea and vomiting were present a few days ago, but have now ceased, and there is a return of appetite. Bowels moving once a day; stools hard and white. Took the first dose of *Mangan. Sulph.* this evening. Vomited in twenty minutes after; the matter was greenish and very bitter. Nausea continued through the night.

21st.—2d dose early in the morning. Nausea, but no vomiting or action on

the bowels. 3d dose again produced only nausea.

22d.—4th dose (increased to two drachms) induced vomiting in ten minutes, but no nausea remained after. No stool now for 48 hours.

Haust Ricini.

5th dose: bowels moved twice in the night; character of stools not ascertained.

23d, 6th dose.—Was sick, and vomited a little; remained sick till the middle of the day. The manganese was now suspended. The pulse, which before had been little more than 60, rose to 117; and he complained of severe pain in the head. Bowels confined.

24th.—7th dose in the evening.

25th.—8th dose; which caused no pain or vomiting, but very great nausea, lasting till evening. One thin yellow evacuation.

Suspend the medicine.

26th.—Much worse; very dull and stupid; severe pain in the head; delirium; no vomiting; one dark stool.

27th.—In the same state. Bowels freely evacuated; stools of a soft consistence, becoming pale again. The skin of a deeper yellow.

The cerebral symptoms continued, with some temporary remission, till the 9th of December, when he died.

There was no trace of disease in the liver, gall-bladder, or ducts. The chief lesion was tubercular deposit in the substance of the spleen, which was large, weighing 27 ozs., and softened.

Robert Lawrence, æt. 45, admitted Sept. 9th. Pains in right knee and foot, right shoulder and elbow; no swelling, nor heat. At present (Nov. 20th), joints feel cold to himself. Shifts about to different joints, sometimes in one joint only, with swelling; sometimes in half a dozen, without swelling. Has been in this state twelve months. Appetite very poor; no nausea or pain after eating; bowels free and comfortable.

Nov. 21st.—At 6 A.M. took Mangan. Sulph. 3j. having an empty stomach, and having taken but little for four days. In an hour felt very sick, and vomited a little thin, mucous fluid, greenish-brown, intensely disagreeable, bitter-sour-salt—a compound of bad tastes. No pain in the stomach; no retching; nausea soon went off; slight

headache after; no action of the bowels. This was the second dose; the first, last evening, produced no effect. In the course of the day, one copious dark stool.

22d.—Has taken a 3d and 4th dose without any nausea or action on the bowels. Appetite improved by the medicine.

23d.—This morning, after the 6th dose, one copious dark stool.

24th.—Slept well last night, the first time for three weeks. Appetite much improved; pain chiefly confined to the foot, not troublesome when at rest.

26th.—Has taken eleven doses now. Was purged three times in the night; stools thin, and very white, like parchment. Very little griping; no nausea.

Medicine suspended.

Robert Drewett, æt. 58, admitted October 8th. At the time when he commenced the use of the manganese, he had been suffering seven months from rheumatism. At that time there was pain, swelling, and thickening about the right wrist and fingers, with immobility of several of the articulations, and a good deal of heat occasionally. More or less affection of the elbow and shoulder of the same side.

Nov. 29th.—After the 1st dose (3j.), yesterday evening, he had four thin stools, the colour of which he did not ascertain. Some griping. 2d dose this morning. One thin and pale-yellow stool. Griping and nausea; no vomiting.

Dec. 1st.—After the 4th dose he had three pale-yellow stools. Nausea, which continued all last night. Bowels free again all to-day. Pains the same.

2d.—Bowels rather confined. No pain at the stomach, but slight nausea.

Ol. Ricini, 5vj.

The medicine appeared to have no influence on the arthritic affection, and was therefore discontinued.

William Western, æt. 42, from Angina. Admitted Nov. 15th, with pain, heat, and swelling in the left wrist; pain in both ankles, and painful swelling, with much heat and tenderness in the ball of the fifth toe of right foot. Has been cook during his last passage; and before that, for eight or nine years, was steward. Feverish; furred tongue; constipation; vomiting frequently after small quantities of food. Catarrhal affection also.

On the 20th, the constitutional disturbance having abated under venesection, purgatives, and low diet, he was ordered Manganessii Sulph. 3j. bis die, ex Aquâ Menth. Pip.

21st.—1st dose last evening; bowels moved twice in the night; very copious feculent evacuations, of a brown colour, tolerably natural. 2d dose, this morning, before breakfast. Vomited very shortly after breakfast; the matter ejected was yellow, and very bitter, the taste persisting in the mouth for several hours. Pains much the same.

22d.—Has taken a 3d and 4th dose without vomiting or nausea, being exhibited about half an hour after eating, instead of when the stomach was empty. Two thin and dark evacuations. Pains better.

23d.—After the 6th dose this morning vomited very shortly; nausea continued for several hours after, and belly became sore and uneasy. Two evacuations. No pain in the joints.

To suspend the Manganese.

From this time there was no acute articular pain, but much stiffness. The soreness in the belly did not disappear till the 27th, after which the bowels became a good deal constipated.

In this case the acute articular affection had only existed for three days before admission.

William Gunn, æt. 40: admitted Nov. 11th. Subacute articular rheumatism. On the 16th Nov. he commenced the Sulphate of Manganese in drachm doses thrice a day. He had then suffered from affection of the left arm and shoulder, and of both knees and ankles, for nineteen days. There was, on admission, swelling and heat about the joints, but this had subsided. He now complained of pain and stiffness in them; the feet swelled after exertion.

Nov. 21st.—Took the 1st dose last night, which caused nausea for an hour; 2d dose caused a greater degree of nausea, and lasted for a longer time; no vomiting. In the course of the day passed one semi-fluid, copious, and very dark stool.

22d.—3d and 4th dose; no nausea, vomiting, or purging; pains worse, owing to the cold weather; appetite improved since he took the medicine.

23d.—5th and 6th doses; no nausea or purging; pains the same; increase the dose to 5j.

24th.—7th dose; no nausea; bowels not free for 48 hours: 8th dose; appetite good.

Pil. Cathart. gr. x.

25th.—9th dose; one copious natural evacuation; 10th dose; pains a little better.

27th.—Bowels move once a day; stools thin and brown, not very dark; pains in the knees and feet worse, probably owing to the cold weather.

28th.—Four thin and brown stools in the last 24 hours; pains worse.

29th.—Two stools; joints swollen again. After this the manganese was continued one or two days longer, without any appreciable affection of the disease, though it decidedly improved the appetite. He now began to suffer from venereal ulceration of the uvula, and the manganese was replaced by the iodide of potassium.

ANALYSES AND NOTICES OF BOOKS.

“L'auteur se tue à allonger ce que le lecteur se tue à abréger.”—D'ALEMBERT.

Elements of the Comparative Anatomy of the Vertebrate Animals, designed especially for the Use of Students. By RUDOLPH WAGNER, M.D. Professor of Comparative Anatomy and Physiology in the University of Göttingen, &c. &c. Edited from the German by ALFRED TULK, Member of the Royal College of Surgeons, of England. London: Longman and Co. 1845.

RUDOLPH WAGNER, Professor of Physiology, Comparative Anatomy, and Zoology, in the University of Göttingen, was born at Baireuth, in the year 1805. He displayed at an early period a marked predilection for the study of natural history. After taking the degree of Doctor of Medicine at Würzburg, in 1826, he repaired to Paris, where the greater portion of his time was spent in the Garden of Plants, of which the illustrious Cuvier was then the presiding genius. He subsequently visited the coasts of Normandy and the Mediterranean; was zealously engaged, during several months' residence in Marseilles and Nice, in investigating the zoological relations of the lowest

classes of organized beings. From Nice he sailed to Sardinia, where he pursued those curious researches concerning the osseous breccia, which were afterwards submitted to the Academy at Munich. In the year 1840, he was appointed to the chair at Göttingen, as a meet reward for his labours and talents. On none other could the mantle of the venerable and distinguished Blumenbach have more aptly fallen. His works are no less remarkable for perspicuity of arrangement than for practical import. The one before us, which reflects great credit upon Mr. Tulk's editorial qualifications, evinces a thorough knowledge of the subject. As an elementary treatise, it cannot fail to supersede the now obsolete manual of the author's predecessor. In short, after careful perusal, we have no hesitation in recommending it to every student desirous of gleaning information regarding a collateral department which has served to clear up many of the dark and hidden things in physiological science.

The following extract exemplifies certain peculiarities touching the venous system :—

“Valves occur in the *Veins* of the body, and frequently, even as in the Ox, in the portal veins, where they are wanting in Man. The trunk of the superior vena cava is very frequently double, in individual animals from all the orders, as in the common Bat, Hedgehog, Squirrel, Ornithorynchus, Elephant; as a rule, however, it is single, as in the Apes, Ruminantia, most Carnivora, &c. The inferior vena cava is commonly dilated in diving animals, previous to entering the heart, and while yet within the liver, as in the Seals; in a less degree also in the Dolphin and Otter, still less so in the Beaver and Ornithorynchus; in these it forms a true sinus like that of Fishes. This large size of the veins, in relation to that of the arteries, exerts unquestionably an important influence upon the circulation and the process of diving; and the discovery is a remarkable one, of a peculiar annular muscle, about an inch in breadth, which is met with in the Seals on the trunk of the inferior vena cava, above the diaphragm and venous sac, and which can cut off the return of blood to the heart. In the Cetacea remarkably developed ve-

nous plexuses occur; one of these lies, *e. g.* in the canal formed by the inferior spinous processes of the tail; another, much more conspicuous (*plexus iliacus*), lies between the psoas muscle and the peritoneum.”

It has been surmised that in certain diseased states the urinary organs and the liver are so closely dependent upon each other that the functions of the one might sometimes supply those of the other. That they are intimately connected is illustrated in the instance of reptiles which “possess a double *Portal system*, one for the liver, and one for the kidneys, and both of these exhibit somewhat different relations in the several orders. In the frog the veins of the intestinal canal of the spleen, &c. concur to form the vena porta of the liver; those of the abdominal coverings, the urinary bladder, and partly of the posterior extremities from the portal vessel of the kidneys, while the efferent veins from the latter organs constitute the trunk of the posterior vena cava, into which the blood returning from the sexual organs and liver is poured; some of the veins of the abdominal parietes empty themselves into the umbilical vein.”

Subjoined is an account of the poison glands of the Ophidia :—

“The poison-gland corresponds in some measure with the parotid salivary gland, and agrees most strikingly in situation with the latter in the Venomous Serpents, having posterior venom-teeth, *e. g.* Dipsas, Homalopsis, where it lies more freely, not invested by any fibrous tunic, and has a short excretory canal. In the typical Venomous Serpents, as Vipera, Naja, Crotalus, Trigonoccephalus, the poison-gland is situated more behind and beneath the eye, consisting of short tubes in Naja, or of hollowed ramified lobules (Trigonoccephalus), and is surrounded by a dense, mostly double fibrous sheath, this again being covered by a layer of muscular fibres, which proceed partly from the temporal muscle, and serve to compress the gland and force its contained secretion into the excretory duct; the latter courses along the external surface of the superior maxillary bone, and enters an opening placed at the root of the poison-tooth. The situation and structure of the poison-gland is similar in the Aquatic Serpents (Hydrus and Hydrophus). This gland occurs in an

unusual situation in *Causus rhombeatus*, being ensiform, situated in a channel-like cavity, and extending to the 18th or 19th vertebra, so that it reaches over more than a seventh part of the whole length of the body; its excretory duct extends from the poison-tooth to behind the quadrate bone. The ejection of the poison into a living animal is accompanied by peculiar and frequently fatal effects."

One of the most interesting chapters in the whole book is that upon the organs of voice and respiration in birds. After demonstrating in a very lucid manner the mechanism of the superior larynx and trachea, the author passes on to describe the *inferior or bronchial larynx*, in which the voice is produced, and which constitutes a special peculiarity of the class. This, from the very extensive series of modifications it presents, necessarily offers a wide field for inquiry. In singing-birds, and those birds generally which are provided with what is called a true *muscular vocal apparatus*, including the ravens, from the power they possess like parrots of imitating the human voice, the inferior larynx is highly complicated. As a general rule, the singing-apparatus is made up of five well developed pairs of muscles, very strongly marked in the nightingale and other small singing birds.

"Two anterior and three posterior pairs of muscles may be distinguished as belonging to the inferior larynx. In front a long elevator muscle (*m. levator anterior longus*) arises tolerably high up from the trachea, and is firmly attached to the second bronchial demi-ring, the anterior extremity of which it draws upwards and outwards, and so widens the larynx. In like manner the transverse elevator (*m. levator anterior transversus*) arises in front, but obliquely, from the external part of the superior border of the tympanum; it proceeds in the direction forwards, and is attached by its inferior extremity to the anterior part of the second and third bronchial demi-rings, and to their interjacent membrane; elevating and drawing these parts also in the direction outwards. By both of these muscles, as well as by the *m. depressor tracheæ s. sterno-trachealis*, which arises externally from the tympanum and passes forwards to the border of the sternum, the cavity of the inferior larynx is

shortened and dilated. The *membrana semilunaris* and the *ligamentum vocale externum* will be also synchronously stretched in a variety of ways by the action of these muscles, joined to that of the three posterior pairs, the description of which will now occupy our attention. The posterior long elevator (*m. levator posterior longus*) arises high up behind the corresponding anterior elevator muscle, and is inserted posteriorly into the extremities of the second bronchial demi-ring, which it draws upwards, and at the same time rotates the third. The posterior short elevator (*m. levator posterior*) is partly covered by the former muscle, but is situated more in the direction backwards and inwards, and at its origin from the upper part of the tympanum abuts closely against its fellow of the opposite side, and is attached higher up to the posterior extremity of the first bronchial arch, which it serves to elevate. The fifth pair of muscles is situated between the posterior long, and the anterior transverse, elevator, and is called the oblique elevator (*m. obliquus posterior s. rotator posterior*); it arises externally from the superior border of the tympanum by a short and thick muscular belly, passes obliquely backwards, and is inserted into the posterior extremities and lower border of the second bony arch, which it rotates and draws in the direction outwards."

The trachea here consists of a short bony tympanum or drum, constituting its inferior extremity, and usually formed by the early coalescence of three rings. The tympanum is divided as usual inferiorly by a transverse or cross bone. From the superior border of this the semilunar membrane of Savart rises. This membrane is of essential importance to the production of song, or the power of uttering articulate sounds; since when it is absent or slightly developed the voice is feeble or has but little variety of tone.

The voice of birds appears, like that of the human subject, to be produced by the combined vibrations of the laryngeal membranes and the tongue. The flute-like tones of the singing birds are doubtless, observes our author, accomplished by a vibration of the whole column of air while passing through the trachea.

MEDICAL GAZETTE.

Friday, February 14, 1845.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

GENERAL LEGISLATION NECESSARY.

At a special meeting of the members of the Liverpool Medical Reform Committee, and of the Local Council of the Provincial Medical and Surgical Association, held upon the 6th current, for the purpose of considering a communication received from the Society of Apothecaries in London, it was resolved unanimously—

"That this meeting, although sincerely desirous of co-operating in any measure calculated to elevate the position of the general practitioners, considers that, in the present stage of medical affairs, it does not possess sufficient information to form any decisive opinion on the subject.

"This meeting has every confidence that, in the amended Bill of Sir James Graham, the interests of the general practitioners will not be lost sight of; while it is not prepared to decide whether those interests would be best consulted by including the general practitioners in the Charter of the College of Surgeons, or by a separate and independent incorporation."

We regard the above as a very significant document at the present juncture. It conveys the sentiments of our medical brethren in Liverpool—a town which ranks next to London in commercial importance.

We have no hesitation in affirming that in the amended measure of the Right Hon. Baronet the interests of the whole profession will be most carefully considered, and that means of protection will be afforded to the public which no mere corporation could ensure. The practitioners of Liverpool have therefore done wisely to pause before sanctioning any scheme which

might possibly tend to impair the usefulness and respectability of the body to which they belong.

We would say to the general practitioners of England, that if they are bent upon their destruction, they will persist in demanding a charter, which probably would not be withheld if they persevere in urging their claims with unity and concord. We admit their perfect right and title thereto; that, indeed, we never disputed; but we have unflinchingly raised our voice against it as a thing imminently perilous to their interests and well-being. We are swayed by no party motives; we have only at heart the dignity and respectability of the profession at large, to uphold which ever has been, and shall be, our earnest and strenuous endeavour.

We are fully sensible that there are at the present time debasing and detrimental influences operating both from within and from without, which must needs be checked and, if possible, exterminated*. But we are loth to believe that partial legislation for one class alone would be an appropriate remedy: we maintain, on the contrary, that it would tend merely to promote dissension, and retard the progress of medical knowledge.

We are anxious for the establishment of a governing board in connexion with the State, with the Minister

* A most glaring illustration of the low pass to which things have come is instanced by the proceedings of some hapless sons of Esculapius at Glasgow. It appears that no less than twenty-seven surgeons attached to friendly societies for the poor, volunteer attendance and medicines at the rate of *thirty pence a-year* for each member, and have issued an intimation that their private patients can be attended on the same economical terms. This circumstance justly gave rise to the gravest suspicions as to the character, skill, and medicines of these "society doctors"; and in consequence of a requisition presented by 118 practitioners to the President of the Faculty of Physicians and Surgeons, a numerous meeting of the medical profession was convened, in which their disgraceful conduct was very properly exposed and denounced. Does not the above fact betoken a necessity for scouring our ranks of the under-bred, half-educated hucksters with which they are overrun and polluted?

of the Home Department, which shall take cognizance of all branches, including medicine, surgery, and pharmacy. Let one uniform standard of medical and surgical qualification be required of every candidate for practice throughout the United Kingdom; and let a sound preliminary education in science and literature be an invariable prerequisite. The restrictive means, together with the system of registry about to be introduced in the forthcoming Bill, will afford the best bulwark against the encroachments of the ignorant and incompetent. Thus the community, as aforesaid, will be protected, and the character of the profession exalted. If adequate restraints are enforced in the law, a profession which is before the public, and where every one can judge of the individual as he produces himself, for a much stronger reason ought they to be in the profession of physic, which is a domestic art, and practised *coram non judicibus*. In the one there is ample guarantee for a man's conduct and skill, in the other none, so far as the public is concerned. Yet the former simply involves the rights of the person and of property, while the latter has to do with the healths and lives of her Majesty's lieges.

It is understood that in the event of Sir James Graham's Bill passing into a law, a supplementary measure respecting the sale of drugs will without delay be submitted to the consideration of parliament. If the statement recently put forth by a member of the Pharmaceutical Society* be correct, something of the kind is rigorously called for in this "drug-damned" country of ours. The writer hazards the assertion that

in no land in the civilized world is the science of pharmacy in so low a condition as in that of Great Britain; and nowhere is the systematic sophistication of drugs, chemicals, and pharmaceutical preparations, carried on so extensively, and with so much impunity. Had he taken a trip across the Atlantic, we think he would have found the parties in the United States rather ahead of our compatriots in this particular. According to the writer, the Pharmacopœia is a dead letter, a sort of obsolete code more honoured in the breach than the observance, "for it is tacitly permitted, and justly so, to deviate from the directions laid down therein, in the preparation of chemical compounds whose constitutions are the same, independently of the processes followed in their manufacture; and it is also notoriously the custom amongst the Pharmaceutists almost invariably to depart from the instructions given, in the preparation of those bodies which do not possess a definite constitution, and which are mostly of animal and vegetable origin."

We are sorry to hear this, because the Examiners at Apothecaries' Hall have uniformly insisted that their candidates should evince a practical knowledge of that "obsolete code." While on this subject we would recommend there being one general pharmacopœia for the United Kingdom. Having three pharmacopœias as at present is quite preposterous, and often perplexing.

After animadverting upon certain malversations of the craft, the writer avers that such could not occur in France and Germany, where the chemists and druggists are infinitely better educated, and subject to periodical visitations by qualified persons appointed for the purpose of ascertaining the quality of, and the means employed in the preparation of the remedial agents ordered by the pharmacopœia. We are inclined to

* "The Pharmacopœia a Dead Letter; or, an Exposure of the Systematic and Fraudulent Adulteration of the Preparations of the Pharmacopœia, with Suggestions for its Prevention. By William Bastick, Member of the Pharmaceutical Society, and late a Student at the University of Giessen."

ascribe more of the improvement in the above countries to the system of education, than to the mere inspection of apothecaries' ware. The plan of examining the shops, formerly carried into effect three times a year by the censors of the College of Physicians, assisted by the Wardens of the Apothecaries, was looked upon as a solemn farce, and eventually abandoned. Indeed, from the manner in which it was executed, it proved totally inefficient in preventing the sale of falsified drugs. We think the Pharmaceutical Society deserves great credit for the efforts they have made, as regards instruction; but more is wanted before they can assume a proper footing.

Every person in short, to practise pharmacy should be licensed by the above mentioned governing board, after due examination, and be all times thereafter amenable to its jurisdiction. The following is the writer's proposal—

“Let the pharmacist have a position in any scheme of medical reform; but let it be well defined. Let its tendency be not to make them bad medical practitioners, but skilful pharmaceutical ones. Let its object be gradually, if not at once, to wean general practitioners from the practice of pharmacy, and chemists and druggists from that of medicine. Then the progress of education, and consequently of respectability, will diminish the desire to adulterate, and increase the means of detecting such adulterations.”

Were chemists and druggists alive to their own interests they would lower the charges for preparing, compounding, and dispensing physic. The present prices are quite exorbitant, and have operated as a great obstacle to medical men prescribing. Most general practitioners, we are persuaded, would willingly alter their system, and receive a moderate fee for their visits, provided chemists were ready to co-operate, and be content with smaller profits than they at present exact. Were this the case, we have no doubt the latter would

increase their business four or five fold. We do not wish to dictate the rate at which any man should dispose of his corporeal exertions, but we are satisfied that some compliance with the above suggestions would prove beneficial to all parties.

MOVEMENT IN THE PROFESSION.

WE have received the copy of a memorial lately addressed to Sir James Graham by the Gloucestershire Medical and Surgical Association. The memorialists express unfeigned thanks that Government should have undertaken the important yet difficult task of amending the present anomalous and defective state of medical practice, and that Sir James should have afforded the profession an ample opportunity for considering the measure previous to its discussion in Parliament. They acquiesce in the principal provisions of the Bill, but are of opinion that the constitution of the Council of Health needs further consideration, inasmuch as the great body of medical practitioners are not duly represented. They trust that the principles of protection against unlicensed practitioners may be more extensively applied than was apparently contemplated; that stamps and patents to medicines be withdrawn; that quack advertisements be prohibited; that all persons undergo the same preliminary education; that some fixed period for medical studies be required of the general practitioner; and that the age for admission into the profession be at least 22 years.

A circular has reached us from the Association of General Practitioners in Medicine, Surgery, and Midwifery, dated February 11th, 1845, wherein the Committee point out the necessity of the general practitioners in the country earnestly entreating the members of Parliament of their respective localities to oppose, by every constitutional means, any Bill for the regulation of medical practice which does not embrace for the general practitioner the principles of medical reform contained in the “Suggestions for Heads of Charter,” which were presented to Sir James Graham previous to the opening of Parliament.

OBSERVATIONS

ON THE

PRACTICE OF MIDWIFERY

HAVING BEEN CONSIDERED AS A CAUSE
FOR PRECLUDING ITS PRACTITIONERS
FROM THE HONOURS OF THE COLLEGE
OF SURGEONS.

To the Editor of the Medical Gazette.

SIR,

It is very difficult to understand why the practice should so exclude, because midwifery is essentially surgery, and there are no other duties in surgery more important as regards the preservation of life or the interests of society. Even when nature performs the operation in the easiest possible way, the assistance required is purely surgical—it is manual. What are the more important aids required? The changing the position of the child in utero, when it is found to be such as to preclude the operation being finished by nature; *therefore* involving the death of the mother and the infant: here a manual operation of no small difficulty is to be performed, and much depends on the time at which, as well as the manner in which, it is performed, as to the safety of *both* lives. In cases of puerperal convulsions, in cases of flooding, in cases where the growth of tumors obstructs the delivery, in cases of deformity of the pelvis, in all these the aid required is essentially surgical; and in the practice of surgery there is no situation which requires more judgment, more decision, more mental firmness, than in the latter, when it becomes the awful duty of the surgeon to decide at what period of time he is justified in destroying the life of the infant, to ensure the safety of the mother, whose life also may be placed at hazard by too long delay, arising from a humane desire to save the child—the operation, dreadfully painful to the feeling mind, is also sometimes effected with great difficulty, even after the privation of life; (I once saw it fail, where three able men were present, from the inconvenient size of the child.) I ask, is it not strange, that the practice and performance of duties so important, *so purely surgical*, and so dependent on anatomical knowledge, should have excluded its practitioners from the honours of the profession, whilst the College have certified them to be competent to practise in all its branches? Is it not rather matter of surprise and reproach, that at the public examinations for diplomas, no one is ever questioned as to the knowledge of this (as I have shown) most important part of surgery? Is it not an anomaly, that the extending the usefulness of the principles, in which he was examined, should lessen his rights? Midwifery, then, partakes as essentially of surgery

as of the practice of medicine; it is a natural combination of the two, and no man is qualified for it unless he be a *good surgeon*; so is it manifestly an injustice, that the practice of it, so useful to others, should be injurious to his interests! I will add, that although exclusion be, or was, denounced against the *general* practitioner, there is not a surgeon, from the sergeant-surgeons, to the humblest, who *professes* to be purely a surgeon, who does not *willingly* pocket fees for advice, not in cases of medical surgery, but in cases belonging purely to the physician. This is done covertly, the other openly, and I believe it can scarcely be avoided, but it shows the impropriety of the exclusive system.

One word more: the requiring old practitioners to undergo examination is absurd. They were formally declared “able to practise their art,” and is it supposed that time and experience lessen their fitness? They rub off the technicalities which are used in examination, but render themselves fitter practitioners.

SENEX.

REMARKABLE CASE OF POISONING WITH ARSENIC.

BY PROFESSOR WÖHLER.

THE suspicion that the widow * * * residing at * * *, three times married, had poisoned her two last husbands, gave occasion to their corpses being exhumed and subjected to chemical investigation. The presence of arsenic was most undoubtedly discovered in both. The greatest quantity was found, however, in the body of the second husband, although it had lain seven years in the grave. This affords an additional proof of the possibility of detecting arsenic after a long period has elapsed, and merits attention on that score.

In order to get at the arsenic, the whole of the soft parts were dried and burnt along with nitre, a procedure preferable to the French method of carbonizing by means of oil of vitriol; inasmuch as by the employment of the latter minute portions of the arsenic may escape, in the form of volatile chloride of arsenic, when chlorides of sodium or ammonium happen to be present in the corpse.

It deserves notice in a medico-legal point of view, in reference to the comparatively small quantity of arsenic traced in the body of the last husband, who had died six months previously and after protracted illness, that he had taken for many weeks before decease, by way of medicine, phosphorized oil in the shape of emulsion, and had thus consumed 16 grm. of phosphorus. On examining the stock of phosphorus in the apothecary's shop where the prescription had been made up, it was found contaminated therewith,

and containing not less than half a per cent of arsenic.

Independently of all medico-legal considerations which this case involves, it shows the necessity for testing phosphorized drugs for arsenic. For this purpose the phosphorus ought to be melted, and then briskly agitated while molten with a mixture of chromate of potash and sulphuric acid, in order to remove any arsenic. Another point to determine was, whether arsenic is really held in solution in the pharmaceutical preparations of phosphorus.—*Liebig's Annalen*, October 1844, p. 141.

HOMICIDE BY AN UNQUALIFIED PRACTITIONER.

AN individual of the name of Bergeron administered a potion to a *demoiselle* Fauvelle, which caused her death. Not appearing when summoned before the court on a double charge of homicide by imprudence, and the illegal exercise of medicine, the said Bergeron thereby allowing judgment to go by default, was amerced in a penalty of 500 francs.—*Journal de Chimie Médicale*, Dec. 1844.

LECTURES
ON THE
NATURE AND TREATMENT OF
DEFORMITIES,

*Delivered at the Bloomsbury Square
Institution.*

BY R. W. TAMPLIN, F.R.C.S.E.
Surgeon to the Institution.

Contraction of the knee-joint in the straight or extended position—congenital—non-congenital. Case of congenital contraction of the thighs, knees, and feet. Causes of non-congenital contraction: injuries to the joint—position—chronic inflammation. Treatment: surgical and mechanical—division of the rectus femoris. Contraction of the hip-joint—congenital—non-congenital. Causes of non-congenital: cerebral or spinal irritation or disease—injuries to the spine—position—rheumatism—idiopathic inflammation. Treatment: mechanical—surgical and mechanical—section of rectus femoris, of tensor vaginae femoris, and adductor longus. Mode of performing the operation.

I HAVE now, gentlemen, to point out to you another contraction of the knee-joint, viz. contraction in the straight or extended position,—the patient suffering from what is called “stiff-knee.” This is a very rare condition of the joint, but is nevertheless both congenital and non-congenital. I have met with but one instance congenital, and that in an infant three months old, in whom the thighs were also contracted in the flexed position, and the feet both contracted, the one in the form of talipes varus, the other talipes valgus; the latter, however, differing from valgus, inasmuch as the anterior half of the foot, that is, from the astragalus, was abruptly everted, and fitted completely in the concavity formed by the foot affected with varus—vide fig. 1. The thighs being

FIG. 1.

An illustration of congenital contraction of the feet, knees, and hips, as described.

flexed upon the pelvis, the knees extended, and the feet thus contracted, were kept constantly lying on the abdomen, chest, and face of the little patient; and when the leg or legs were forcibly drawn down, they returned with an elastic impulse to their contracted position. It is the only case of the kind I have met with, but is confirmatory, in my opinion, of the cause I have so often stated to you of those congenital contractions which exist without cerebral disease, or without malformation of parts, namely,

position *in utero*. This child was born with the breech presentation, and had evidently, during its uterine existence, possessed very little, if any, power of moving the lower extremities out of the position in which they presented themselves, and which position would certainly adapt it to the smallest possible space it was capable of being placed in. There was no malformation, or any evidence of disease existing, or having existed, in the nervous system. The child was of the usual size, and perfectly healthy in every respect, so that I can assign no cause excepting the one mentioned. With regard to the non-congenital, you will generally find that it arises either from disease or injury to the joint. In the cases I have met with, chronic inflammation of the joint has been the original cause, producing in the first instance contraction in the flexed position, which, however, has been removed by the gradual extension kept up by means of a tin splint, before the contraction had become permanent; and when removed, the joints have been kept constantly in the extended position, and thus terminating in contraction of the extensors, which is most evident; so that it appears that muscles have not the power of retaining their proper functions if kept constantly at rest, but become rigidly fixed up to the point at which they have ceased to be elongated or drawn out, no matter what muscle or set of muscles may be so circumstanced, whether the extensors or flexors, &c. &c.; but although they might appear to be permanently shortened, yet I believe that no change in their structure takes place beyond the rigidity mentioned, and a want of development occasioned by their passive condition; and the cases mentioned in the early part of the course are conclusive testimony of this being the fact.

The cases that have presented themselves arising from injury to the joint have terminated in ankylosis, and of course have become irremediable. In one case, however, the adhesion was ruptured by force, and the leg flexed to about two-thirds of a right angle; afterwards slowly extended; but it occasioned great pain, and ultimately became fixed in its original position; so that I have not much to say on this cause. Patients thus afflicted are, as you must perceive, in a much better condition than those who suffer from either of the contractions before mentioned, but are nevertheless exposed to much inconvenience, and considerable lameness; as, in the act of progression, the leg affected is thrown or carried round, forming almost a semicircle on each step taken, the only means the patients possess of walking with any degree of comfort; for if they attempt to carry the leg straight before them, they are constantly liable to trip or fall from any

slight impediment that they may happen to meet with; and, of course, any very active employment can scarcely be followed.

Treatment.—The treatment, in these, as in the other contractions, will consist of mechanical solely, or surgical and mechanical, according to the rigidity met with, and the length of time the contraction has existed. In the congenital case just mentioned, after operating upon the feet and removing the contraction, I first, and for three months, attempted to flex the knees by mechanical means. The left knee yielded to that treatment; the right remained much in its original condition. I could flex it, and keep it flexed during the time the instrument was on, but upon removing it the leg was instantly extended, and remained so. I therefore determined to divide the rectus, which I did in the following manner: the leg was forcibly flexed, and held so by an assistant; the child lying on its back, I then introduced a small sharp-pointed knife on the inner margin of the rectus, about an inch and a half above the patella; and as soon as I imagined the point of the knife was parallel with the under surface of the muscle, I depressed the handle, and passed it beneath as far as its outer edge, then turned the sharp edge towards the muscle, and divided it transversely from below upwards. A pledget of lint was applied over the point of puncture, and secured with strapping and bandage; this was allowed to remain for a week, at the end of which time the puncture was healed, and the instrument reapplied (consisting of a simple spring, having attached at each extremity a circular band,—the one for the leg, the other for the thigh, and secured by means of a strap and buckle being applied beneath the joint); extension was again kept up, and in fourteen days the leg was flexed to a right angle with great ease; so that I should advise your adopting a similar course in a case of this description, as it is evident that the sooner the contraction is overcome the better. No ill effects followed the operation, nor apparent inconvenience; and the result has been most satisfactory.

In cases arising from disease in the joint, provided you can flex it without great force, I would advise your adopting the mechanical means alone, which you will do in the following manner. Let the leg be placed and secured in a splint, similar to that mentioned for contraction in the flexed position, with the metal plate in front of the thigh, as well as behind, and one also to cover the anterior surface of the leg. Then, with a male and female screw attached behind, gradually flex the leg—more or less rapidly, according to the feelings of the patient—and when it is flexed to or beyond a right angle, let it be extended again: as soon as this is

accomplished, direct the patient or friends to flex and extend it alternately once or twice daily, until free motion is obtained, when the screw should be removed, to allow of the patients exercising voluntary motion, as much as can be done twice or oftener daily, after which, let the screw be reattached and retain the joint during the night, and also during the intervals of exercise in the semi-flexed position, so that neither set of muscles shall regain a preponderance of power; for you must always bear in mind that there is a constant inclination or tendency to contract, if a preponderance of power exists. As soon as the patient can flex and extend the joint voluntarily, let the instrument be removed for a portion of the day, and let exercise be taken; in this way you will effectually remove the contraction; do not, however, omit the use of the instrument until all tendency to contraction is overcome, for rely upon it, should you do so, a return of the contraction will follow. A case occurred to me, some time since, of a gentleman, aged about 20, which had arisen from inflammation in the joint, followed by contraction in the flexed position; this was removed by the application of splints, and the patient was ordered to keep the leg constantly extended: this he had followed up for two years; at the end of which time he consulted me, when I found the rectus rigidly tense, and any attempt to flex the leg with the hand futile; I applied the splint mentioned, and kept up constant extension upon the muscle, and in three weeks succeeded in flexing the joint to a right angle; I then re-extended the joint, and proceeded in the manner described, until he could voluntarily flex and extend it very nearly to a right angle. He became, however, impatient, and left town, promising to persevere at home; I have since heard he has made but little progress, and in all probability the joint will return to its original condition. Of course, the moving of a joint which has been for a long time in one position is attended with some pain, and requires the greatest possible perseverance, both on the part of the medical attendant as well as on that of the patient, for unless the treatment is most unremittingly followed up, there is little prospect of a cure being effected.

In cases that have arisen from adhesions in the joint, when the joint is immoveable, and when upon forcibly attempting to flex it no pain is experienced, I would not advise your having recourse to any means of restoration, as the patient possesses a limb that is comparatively useful, although limited in its motions, whereas if you rupture the adhesions, the probability is you will not eventually improve the condition of the patient—at least, I have not seen any permanent good arise from such treatment; al-

though you may succeed in flexing the joint for a time, yet the chances are that it will return to its former state, as it can scarcely be expected that the secretory surface of the synovial membrane, or that the ruptured extremities, will assume a condition compatible with free motion. With this, gentlemen, I conclude the contractions of the knee joint, and shall now proceed to one scarcely less difficult or less important, namely—

Contraction of the hip-joint.—Contraction of the hip-joint is both congenital and non-congenital, and will be found either to consist of contraction in the flexed position simply, or, as is most frequently met with, flexed and adducted combined.

The only case that I could distinctly trace as being congenital was that I have just now related (vide fig. 1), although some cases were stated to have been congenital, in which the general spasmodic condition also co-existed; in that case, however, the contraction was confined to the flexors almost entirely. The thighs, it is true, were held in contact, but could be easily separated, and would at times remain so; but from the little patient possessing no control over the extensors, no opportunity was presented for its abducting the thighs; since the contraction of the knees and feet has been removed, the thighs are moved in either position by the voluntary effort. I have not met with a congenital case in the adult or youth, so that, if it has occurred, in all probability the weight of the extremities, and the constant extension the thighs would naturally be subjected to, have overcome the contraction.

The non-congenital arise from cerebral or spinal irritation, injury to the spine, position, from strumous disease in the hip-joint, or its neighbourhood.

In the cases arising from cerebral or spinal irritation, you will find either paralysis of one or more muscles, especially of those below the knee, and which are generally the extensors of the legs, and flexors of the feet, for you will perhaps never meet with the contraction from this cause, without contraction of the knees and feet also of one or other of the forms I have mentioned to you, or else a general spasmodic condition of the muscles, affecting the lower extremities solely, or, as is most generally the case, a spasmodic condition of all the voluntary muscles, and I may add also, a contraction of the adductors combined; as an invariable consequence, the one leg being thrown and retained constantly over its fellow. A case now in the Charity illustrated this most fully, for, when admitted, both thighs were retained, as many of you must have seen, in their extreme amount of adduction, which, with the contraction in the knees and feet, gave the boy more the appearance of some hideous malformation. In these spasmodic cases, then, you have, in ad-

FIG. 2.

Example of contraction of the thighs in the adducted and flexed position, combined with contraction of the knees and feet. The feet, however, in this instance, were both contracted in the form of talipes varus. In the case from which this cut was taken, all the voluntary muscles were spasmodically affected.

dition, contraction of the knees in the flexed position, combined with talipes varus of one foot, talipes valgus of the other, (vide Fig. 2) ; the lower extremities being perfectly useless, but without any disease or disorganisation of the joints themselves, as also, in the congenital contraction.

In cases arising from injury to the spine, paralysis is the immediate result, and upon recovery from which the knees and feet will be found very generally to have become contracted: when, from the constantly flexed position, the thighs are kept in, to enable the patient to swing himself between two crutches, contraction of the flexors takes place, so that after the deformity has been removed in the knees or feet, the thighs will be found contracted, and of course present a great obstacle to the patient walking with any degree of comfort. I attended a gentleman eighteen months since, for contraction of the knee-joint in the flexed position, which had existed since his infancy; after re-

storing the leg to the straight position, I found, on his attempting to use it, that the flexors of the thigh had become contracted, solely from that limb having been kept flexed, to enable him the more conveniently to move about with the assistance of a crutch.

In rheumatic inflammation affecting the joint, unless the means employed give speedy relief and cut short the attack, a change in the secretory surface of the synovial membrane quickly takes place; adhesions are formed, and perfect ankylosis results; so that, as in the knee, unless the patient presents himself within a short time from the termination of the acute attack, you will in all probability be unable to adopt any means which shall produce a beneficial result.

Idiopathic inflammation of the hip-joint assumes a more rapid, violent, and destructive character, than in any other joint; for, in a few hours, a patient attacked with it suffers from disorganisation, to a greater or less extent, of the cartilage of the acetabulum or head of the femur, producing, if not contraction, a grating sensation from disorganisation, which frequently terminates in the hardened ivory condition of that portion of the cartilage which has thus suffered, and if the patient is confined long with the attack, contraction of the flexors and adductors results; for in this instance, as well as in all others, the position instinctively maintained during the attack will be that which occasions the smallest amount of pressure in the articular cavity, and it must be evident that no one could effect this so completely as the adducted and flexed, as the body of muscles acting on the thigh-bone are by this means kept in a relaxed state, and the extensors of the thighs, powerful as they are, become and continue relaxed and passive by the same instinctive efforts which occasion contraction of the flexors and adductors; for if they act at all, they can only do so by first fixing the head of the femur on the acetabulum, which must irritate and increase the inflammatory condition of the joint, and of course add to the pain from which he is already suffering.

The last cause I shall have to mention is strumous disease in the joint, or the neighbourhood of the joint; most frequently in the joint itself. This cause is as serious, if not more so, than either of those mentioned, as it but too frequently terminates in the destruction of the articular cavity, and ligaments connected with it, oftentimes also of a considerable portion of the bones surrounding the joint, as well as of the head of the femur itself, producing a change in the relative position of the bones, and upon the subsidence of the diseased action, contraction of the flexors and adductors will be found, together with more or less shortening of the

entire limb from the loss of substance, and from the displacement of the head of the bone, which as a rule will be found on the dorsum of the ilium, and from the length of time occupied by the restorative process in this affection, under the most favourable circumstances, the contraction becomes proportionally rigid, and will require the greatest care and attention in the treatment. In cases arising from either of the causes mentioned, the nates will be flattened, from the atrophied condition of the muscles which have remained passive; and in each, with the exception of the last, the trochanter major will be found in its proper relative position, admitting of free motion in every direction, as far as the contracted muscles will admit of, provided the integrity of the joint is not disturbed. In the last case, however, you will not only find the nates flattened, but the trochanter major, from the displacement which has happened, project, and of itself present a deformed appearance.

Patients suffering from this contraction are rarely able to use the extremity without the assistance of crutches, and if the contraction exists to a right angle, the leg becomes almost useless; if, however, the contraction does not exist to so great an extent, they can get about by placing the toes on the ground, and by the yielding of the lumbar vertebrae, or by wearing a high-heeled shoe; in either case great lameness and inconvenience is the result, and very frequently contraction of the knee, or of the heel, is a consequence. In those cases of contraction which have arisen without disease in the joint, the only method of walking is either by the head and chest being thrown forward, or by the yielding of the lumbar vertebrae producing lordosis, the nates projecting, so that under any circumstances they are subjected to greater inconveniences than by most of those contractions previously mentioned.

Treatment.—The treatment consists of mechanical, or surgical and mechanical, and, in incipient cases of disease in the joint, local and general means also.

In incipient cases arising from disease in the joint, it has been recommended that two or three years should be allowed to elapse before any attempts are made to remove the contraction. This, from my experience, is unwise and unnecessary, if it is not directly injurious to the patient, which I believe it to be. The plan I have adopted, after the active symptoms of the disease have subsided, is to keep up a constant steady extension, to such an extent only as will not admit of the patient suffering from pain, which can be done at the same time the general health is being attended to, and any local irritant applied, should it be thought necessary: in this way not only is the contraction prevented from becoming confirmed, but the restorative

process is assisted by the limb and joint being kept at rest or nearly so, for it is evident, one of the most certain means of adding to the diseased action already in existence, is by allowing motion of any kind to take place, excepting that only which is of the most passive nature. In these cases, then, I would advise your having recourse to an instrument I have had made, similar to that represented in Fig. 4, which, by its fixing the pelvis, and being also attached by the broad webbing strap to the chest and abdomen, will enable you to keep up any amount of extension on the thigh, first bandaging the foot, leg, thigh, and hip, with a flannel roller; for, as I mentioned to you when speaking of scrofulous disease of the knee-joint, unless the natural temperature is kept up, the restorative process cannot go on.

In cases occurring in the poorer classes, whose means do not allow of their procuring an instrument, I have had recourse to a straight board, corresponding with the size of the back, with an extended portion to correspond with the thigh contracted, webbing straps being nailed on each side of the board, so that the abdomen, chest, and pelvis, may be secured tolerably well: of course a pad must be used, to prevent any undue pressure being made. With this I have succeeded in bringing down the thigh and preventing a contraction from taking place. You cannot, of course, restore any amount of motion, and your attention must, therefore, be directed to bring the thigh straight with the pelvis, which enables a patient to use the leg with comparative ease, and without the use of crutches. In young subjects, provided the disease has subsided, and a short time only has elapsed, the contraction may, as a rule, be removed without an operation, but if in the course of extension any of the superficial muscles are found to be rigidly tense, a division of them had better be effected. In the older subjects, and when the disease has ceased to exist for any length of time, although the new matter may not have become consolidated, you will find the contraction rigid, and scarcely, if any, perceptible motion can be discovered; you must then be guided by the rigidity of the muscles themselves, as well as by the patient complaining of pain, upon forcible extension being kept up, for so long as there is no ossific union you may on all occasions relieve, if not remove, the contraction. A case of this kind was some time since admitted into the Charity, in which the thigh was contracted to a right angle with the pelvis, and the boy could not use the limb in the least (vide Fig. 3). No motion, or trace of it, could be discovered by the use of great force. It was proposed to saw through the neck of the thigh-bone (Dr. Barlow's operation, of Philadelphia), and the father

of the boy assented to its being done. I examined him, however, carefully and repeatedly, and adopting the course I have recommended to you, namely, the keeping up of forcible extension for some time when a doubt exists of ankylosis having taken place, I found the rectus, tensor, vaginae femoris, and adductors, continue rigidly tense, which they would not have been had the ankylosis been perfect, for in that case they are perfectly relaxed; I therefore proposed that the division of as many as possible of the contracted muscles should be first tried, as in the event of that not succeeding the patient would be in no worse condition than he was before: accordingly, this was done. The rectus, adductor longus, and tensor vaginae femoris, were divided, and after the punctures had healed, extension was kept up by the instrument represented in fig. 4,

when I had the satisfaction of finding the thigh yield about half; and although I failed in bringing it into the straight position with the pelvis, yet it was so far reduced that the boy could get about comfortably with a stick, whereas previously his only means of locomotion was with crutches. So that in these apparently hopeless cases great good can be effected.

The mode of performing the operation is as follows:—Let the patient lie on his back, and first feel for the front edge of the tensor vaginae femoris, then introduce a long sharp-pointed knife to its inner side, and as soon as you have carried the knife as far as the breadth of the muscle, turn the sharp edge towards it, and divide it from within outwards; you then proceed to the division of the rectus in the following manner: introduce a sharp-pointed knife on its inner

FIG. 3.

An illustration of contraction of the hip-joint at right angles, taken from a patient about 16 years of age. The contraction had arisen from disease in the joint, which had also resulted in displacement.

FIG. 4.

Diagram of the instrument alluded to for the reduction of contraction of the hip-joint.

margin, at about an inch and a half from the pelvis, pass it perpendicularly downwards, and when the point is parallel with the under surface, depress the handle, and carry the knife horizontally beneath it from within outwards, and divide it transversely from below upwards. The division of the adductor longus will require great care, as although it is rendered prominent by the contracted state, yet it is in close proximity to the femoral vessels, and unless the greatest precautions are taken, risk is incurred of puncturing them. The mode I usually adopt is as follows: direct an assistant forcibly to abduct the thigh, so that the tension may be increased; then with a small scalpel puncture the fascia as nearly as possible to the *outer* edge of the muscle, carrying the knife directly downwards upon it; then introduce a blunt-pointed knife, pass it beneath, and

as nearly as possible horizontally across from without inwards, *i. e.* towards the skin on the inner side of the thigh, turn the sharp edge towards the muscle, and divide it. By this mode you run no risk of puncturing an artery; the complete division of a small branch would be of no moment, as a compress and bandage will effectually control it: you cannot, however, exercise too great caution. After the division, place pledgets of lint over the points of puncture sufficiently large to prevent any venous bleeding, and secure them with strapping and bandage, which you should allow to remain for a week. Afterwards, apply the instrument mentioned, and proceed with the extension as rapidly as the feelings of the patient will admit of. Occasionally you will find only one of the muscles mentioned tense, which of course simplifies the operation. In those cases of contraction which arise from cerebral or spinal irritation or disease, and in which the knees and feet are also contracted, I would advise your operating first on the knees and feet, and when their normal position is restored proceed with the thighs. In some, however, you will be compelled, from the great amount of contraction of the muscles of the thighs, to abduct them before you can conveniently follow up the after-treatment of the knees or feet. In the case I mentioned to you, now in the wards, it would have been impossible to have treated the knees or feet without first abducting the thigh, which was therefore the first step in the treatment, and the boy now has his limbs restored to their natural position: you will therefore be guided according to circumstances. In the slighter cases of contraction, which exist without disease in the articulation itself, you may proceed in the manner described in my last lecture, without operation.

After the leg is brought into the straight position, in cases in which actual shortening of the entire limb exists, let the patient have a boot with a raised sole, made to correspond with the fellow limb, and raised equally from the heel to the toe, when, possessing the free use of the ankle and knee joints, they will be enabled to get about with comfort. In the spasmodic cases, supports from the hips downwards are absolutely necessary to prevent a return to the malposition, and also to enable the patient to take exercise. You will be surprised to see how much better the milder spasmodic cases can walk than could reasonably have been anticipated, although the spasmodic condition of the muscles still exists. A patient lately in the Charity, about 14 years of age, in whom I divided the adductor longus in each thigh, the flexors of both knees, and the tendo-Achilles in each foot, is now walking with comparative ease, and has much improved

since he left the Charity. So that although these are perhaps as little encouraging as any case of deformity you may meet with, yet your efforts must still be directed to do as much as the case admits of, which, to the patients themselves, is not thought insignificant, from the comparative comfort with which they are enabled to move about.

ON
PERICARDITIS, A COMPLICATION
AND SEQUELA OF SCARLATINA :

WITH CASES AND OBSERVATIONS.

By S. SCOTT ALISON, M.D.

Member of the Royal College of Physicians,
London; Physician to the Northern
Dispensary, &c. &c.

(For the Medical Gazette.)

Pericarditis a complication and sequela of scarlatina.—Mortality from scarlatina.—Complications of scarlatina.—Cases of pericarditis.—Period of accession of pericarditis.—Character of scarlatina complicated with pericarditis.—Connection with affection of the kidneys and arthritic pains.—Treatment.

THE most cursory glance at the abstracts of the causes of death in this country prepared by the Registrar-General, suffices to indicate the great importance of scarlatina as a cause of mortality in this country. In the year 1840, the mortality in England and Wales by this one cause alone was no less than 19,816, and in the metropolis 1,954. The mortality from this cause is perhaps rendered still more striking when contrasted with the mortality of two very important diseases, viz. small-pox and typhus. In the same year, viz. 1840, the number of deaths in England and Wales from small-pox was 10,434, being little more than half the number of deaths from scarlatina. Again, in the same year, the deaths from typhus in England and Wales were 17,177; considerably less than the deaths from scarlatina.

The importance of scarlatina as a cause of death is further shewn by the great mortality which this disease has created during the thirteen weeks ending the 28th of December, 1844: the deaths from scarlatina were no less than 872; while the number of deaths from small-pox and measles, although both were epidemic, amounted respectively to 571 and 385.

The abatement of the mortality by scarlatina is an object of the utmost importance, and is well deserving of the best endeavours of the physician. That this is attainable to at least a certain extent there can be no doubt. The remarkable abatement of mortality by the two diseases which have been

referred to, which has taken place in our own time, is pregnant with hope for a similar result in the case of scarlatina. It is true that in respect to the latter disease we have not yet discovered a preventive such as vaccination, and that hitherto no external arrangements have been found to arrest its career, as draining, ventilation, and sewerage, have checked the ravages of continued fever.

The reduction of the mortality by scarlatina to any very great extent, should that ever occur, there is reason to believe will be owing to the discovery of some such process as inoculation of the virus of a mild form of the disease, or of a milder analogous disease, to some improvement in external arrangements, or to an internal revolution in the human economy.

But that the mortality of scarlatina may be reduced in a moderate and even a considerable degree without a process analogous to vaccination, without the discovery of external arrangements protective against the disease, or by a revolution in the human economy, rendering it incapable of undergoing the disease, or less prone to it, there can be no doubt. Improved medicine is capable of effecting this, and until other means are discovered, it must suffice to use this engine, and to attain this end.

Medicine will be improved, and this end attained, according as our knowledge of disease is accurate and complete, and every contribution to the history of disease must consequently be operative to the end of abating mortality.

Notwithstanding that the history of scarlatina has of late years been made more accurate and satisfactory under the able hands of Tweedie, Burrows, Wood, Willis, and others, there is reason to believe that much is still wanting to complete the portrait. The condition of certain organs during the disease is not well known, the complications which are wont to arise are, there is reason to conjecture, not all fully made out, and the nature and importance, and relations of some pathological changes, particularly of the kidney and the skin, which are wont to arise, it is all but certain, have yet to receive much important elucidation.

A more extended knowledge of the complications and sequela of scarlatina will prove highly salutary, both by leading to an increase of precaution with a view to their prevention, and to an improvement in the treatment. It is with this impression that we have ventured to request the attention of the profession to a few facts connected with this disease which have lately fallen under our notice. It is confidently anticipated that these facts will form an useful contribution to the pathology of the disease, and lead to increased watchfulness on the part of

medical practitioners when treating scarlatina.

It has been long familiarly known that scarlatina is liable to be complicated with inflammation of the brain, of its investing membranes, of the cervical glands, and with coma. But it does not appear that pericarditis has been commonly taught as a complication of this disease.

The occurrence of three cases of pericarditis as a complication of scarlatina, in our practice within the last few months, has convinced us that inflammation of the pericardium not unfrequently complicates scarlatina, and has induced us to refer to the various esteemed writers on scarlatina, for the purpose of discovering what notice this complication has received.

A few writers on scarlatina allude to pericarditis as a complication. Dr. George Burrows alludes briefly to this event, in the article *Scarlatina*, in the Library of Medicine. Dr. Robert Willis, in an able article on *Anasarca* after *Scarlatina*, in the 10th No. of the London and Edinburgh Journal of Medical Science, remarks, that in examining the bodies of those who had died of scarlet-fever, he has sometimes found inflammation of the pericardium, and occasionally traces of endocarditis.

Some writers, also, on carditis, have remarked that this disease occasionally arises as a complication of scarlatina. Dr. Joy, in the article *Carditis*, in the Library of Medicine, says: "Pericarditis frequently makes its appearance in connection with the eruptive fevers, and more especially with scarlatina:" and Dr. Copland, under the head *Pericarditis*, in the Dictionary of Medicine, remarks, that "internal carditis appears at an advanced stage of, or during convalescence from, either of the eruptive fevers." Rilliet and Barthez, at page 211 of their joint work entitled *Traité des Maladies des Enfants*, writing on diseases productive of pericarditis, have this passage:—"Il en est deux, toute-fois la scarlatine et le rhumatisme, qui nous semblent, quoique dans des circonstances bien différentes, prédisposer plus que les autres à cette complication; le rhumatisme par analogie de nature, la scarlatine par la facilité avec laquelle elle se complique de l'inflammation des membranes sereuses."

Puchelt, who published at Leipsic, in 1824, a short dissertation entitled, "*De Carditide Infantum Commentarius*," mentions scarlatina, along with many other diseases, as a cause of carditis. He does not say that any of the cases of carditis which fell under his own observation were preceded by scarlatina. Referring to Krukenbergius, he says, "*Passim carditidis cum morbillis et scarlatina conjunctæ, sed obiter, men-*

tionem facit, aliquot ab ipso relatæ historiæ ejusdem suspicionem in nobis movent."

On the other hand, several very able writers and much esteemed authorities both on carditis and scarlatina, make no allusion whatever in their writings to pericarditis as a complication of scarlatina. Burserius, in his *Institutes of Medicine*, is silent on the subject of pericarditis, although he says that in the bodies of several persons who died of scarlet-fever at Florence in 1717, the lungs, pleura, intercostal muscles, diaphragm, kidneys, and intestines, were found more or less inflamed. Dr. Wells, who was amongst the first English physicians who wrote upon anasarca as a sequela of scarlet-fever, makes no mention of pericarditis in his paper published in 1806. Dr. William Wood, of Edinburgh, in his detailed and careful account of the epidemic scarlet-fever of 1835-6, published in the 47th vol. of the Edinburgh Medical and Surgical Journal, is equally silent on this subject. But in this instance, as in others, the silence may have arisen from the disease having been overlooked rather than from its non-occurrence. This is rendered the more probable from a passage in his paper—"but in all the cases in which symptoms indicating an affection of the head and chest were connected with the oedematous state, there was more or less general febrile excitement, and the pulse was occasionally remarkably frequent, with the heart beating tumultuously."

Dr. George Hamilton, of Falkirk, who published a careful account of an epidemic of scarlet-fever, in the 47th vol. of the Edinburgh Medical and Surgical Journal, does not once allude to the subject. Dr. Hepe, in his paper on *Pericarditis*, in the *Cyclopædia of Practical Medicine*, and in his *Treatise on the Diseases of the Heart and Great Vessels*, makes no mention of scarlatina as a cause of the disease. Dr. Tweedie, in his valuable contribution on scarlatina in the same work, does not allude to pericarditis as a complication of this exanthesis. Dr. Watson, in his very practical *Lectures on the Practice of Physic*, does not place pericarditis amongst the complications of scarlatina, but, on the contrary, mentions that the affections of the joints simulative of rheumatism, occurring in the course of scarlatina, may be distinguished from true rheumatism by the absence of implication of the heart. He adds, that in no instance of tumid joints occurring in the course of scarlatina did the heart become affected. Further, there is reason to believe that the profession at large is not sufficiently aware that pericarditis is liable to complicate scarlatina. In conversation with many well-informed members of the profession, both physicians and general practitioners, we have

found that a large proportion of them were not at all cognizant of this complication of scarlatina.

It will, perhaps, appear to the profession, that although pericarditis, as a complication of scarlatina, cannot be regarded as a novelty, that the subject is nevertheless worthy of being submitted to its attention, on account of the omission of the subject altogether by many esteemed writers, of what Dr. Watson says of its non-occurrence in cases of tumid joints, a statement scarcely corresponding with our experience, and on account of its being comparatively unknown to many members of the profession.

The profession will agree with us, we doubt not, in the opinion, that every one of its members should be fully informed on this point, both on account of the great importance and danger of the complication, and from the fact that it is in pericarditis, perhaps, as much as in any other disease, the benefit of prompt treatment is most happily displayed, and in which the evil of oversight on the part of the practitioner is most strikingly and perniciously exhibited. For a happy issue of this complication it is peculiarly necessary that the practitioner's efforts be made "*dicto citius*."

The writer is further encouraged to lay this paper before the profession, from the assurance he has that few discoveries in the history of disease have contributed more to the safety of the afflicted than the almost recent discovery of the very common connection between acute rheumatism and pericarditis.

CASE I.—J. S., æt. 4 years, a fine healthy boy, became affected with scarlatina about the beginning of last June. The disease was smart, attended with considerable pyrexia. The throat was much inflamed and swollen; the eruption was general and vivid, and the cuticle desquamated freely. The child was recovering his health, and was going out a little into the open air, when, about three weeks from the accession of the exanthem, the scrotum was observed to be swollen. From this time the surface of the body began to swell, and the patient became much enlarged from effusion in the cellular tissue. The child was taken to one of the hospitals, where he became an out-patient. Under the treatment pursued, the anasarca greatly diminished, but the child's general health, notwithstanding, became deteriorated.

On the 27th of August, I accidentally saw the patient, when I was requested to prescribe for him. There was then very little effusion in the cellular structure under the integuments, the left testis was enlarged, and fluctuated, effusion within the right pleural cavity was indicated by dulness on

percussion, absence of respiration, and by decided increase in the volume of the right side. The action of the heart was very rapid, violent, and tumultuous. There was great dyspnoea; the patient preferred the erect position; he moved incessantly, so as to oppose great difficulty to an accurate examination with the stethoscope. The pulse was 140 per minute, small and irritable; respiration was 60 per minute; urine non-albuminous; the countenance indicated the greatest anxiety; the features were sharp; the countenance pallid, and the eyes active and bright. The patient was very weak, and evidently dying. Spirits of nitrous ether and cordials were ordered. He rapidly became worse till the 1st September. He was then seized with great restlessness. He called out in the most urgent manner, and frequently attempted to vomit. He died in the course of the afternoon.

Autopsy.—13 hours after death, the body was inspected. *Thorax.*—The pericardium was intimately attached to the pleura-costalis, and contained about six ounces of thick sero-purulent fluid, which rushed out as soon as the scalpel reached the cavity. The pericardium was much thickened, both where it formed the containing sac, and where it invested the heart. The free surface of that part which formed the bag was covered with shreds and patches of lymph, of a faint yellow colour, while the membrane itself was of a rosy hue. That part of the pericardium which invested the heart and the commencement of the great vessels was covered with a dense rough coating of coagulated lymph. A few loose bands of false membrane connected the free surface of the pericardium and that part of the membrane which invested the anterior part of the heart. We add the other morbid signs.

The pleura pulmonalis of the left side was connected with the pleura costalis by means of a few thin adhesions. The cavity of the right pleura was occupied by sero-purulent fluid of a green colour, inoffensive. The right lung was solidified, shrunk, and retracted, lying alongside the vertebral column. The air cells were totally obliterated; a few of the minute bronchial tubes were solidified.

The abdomen.—The peritoneal cavity contained about four ounces of green sero-purulent fluid of less consistence than that found in the thorax. Several adhesions were found between the anterior part of the liver and the corresponding part of the peritoneal covering of the walls of the abdomen. Various pieces of smooth lymph were seen lying upon the liver; one piece of this substance, in the form of a band, accompanied the round ligament. The liver was large, and contained much blood, and the gall bladder was distended. The stomach and smaller

intestines were large, the caput cæcum coli, and the whole extent of the colon, were much reduced in size. The colon, in no part, exceeded the little finger in size, and it was much corrugated. The spleen was healthy. The kidneys were large and firm, $3\frac{1}{2}$ inches in length. The surface was mottled from the presence of minute vessels on the cortical substance, which was somewhat pale; a condition noticed by Dr. Willis in some cases of anasarca after scarlatina. The cortical substance throughout, although pallid, contained many small vessels, and a few very minute granules. The left kidney weighed two ounces and thirty grains; the right, two ounces and ninety grains.

The cavity of the left tunica vaginalis was obliterated, except for a small space in front of the testis. It had been the seat of inflammatory action, and adhesion had taken place. The small remaining cavity was filled with two drachms of sero-purulent fluid of a green colour and of a very thick consistence. The testis was healthy.

CASE II.—16th Nov. 1844.—Frederick Cook, aged 6 years, a well-grown stout boy, enjoying on the whole good health, is reported to have suffered an attack in the left hypochondriac region of an inflammatory character some years ago, from which he made a perfect recovery. He was in perfect health till seven days ago, when he was found to be ailing. The illness proved to be scarlatina; the eruption came out on the second day, was vivid and general throughout the body, and disappeared on the fifth day. During the night of the sixth day he was suddenly seized with violent pain in the præcordial region; he became exceedingly restless, agitated, and he endeavoured to lie with his shoulders raised, and inclining to the right side. The mother remarked violent palpitations of the heart, and becoming apprehensive, requested the writer to see her child. He was seen within twelve hours of the seizure. He complained of severe pain in the region of the heart, increased by pressure in the epigastric region, and by coughing. The soft parts at the præcordial region are lifted to an unusually great extent by the apex of the heart. The impulse of the heart is much stronger than natural, and is felt over the whole anterior surface of the left side of thorax, from the second rib downwards. The hand is lifted by the impulse, as is likewise the stethoscope to such an extent as to cause considerable rubbing on the ear, which might be mistaken for rubbing sound proceeding from the heart. The most cautious examination discovers neither rubbing nor bellows sound. The patient is troubled with a frequent short cough. The pulse is regular, full, and 120 per minute. The expression of face is anxious, and the

eye indicates alarm. Bowels open. Urine rather scanty, high in colour, and deposits sediment of lithate of ammonia.

Venæsectio ad uncias duas. Mistura Vini Antimonii Potasso-Tartratis, et Nitratis Potassæ, sæpe sumenda. Capiat grana duo Calomelanos quaque tertia hora. Applicentur hirudines tres præcordiis.

17th.—The blood was slightly cupped, had no buffy coat; the serum was straw-coloured, specific gravity 1025. The patient has been much better, he has passed a good night, and the pain is much abated; throbbing at præcordia is considerably reduced, but the heart's action is still unusually great; pulse 120 and full; cough is less frequent, face is less anxious; leeches bled well; stools frequent, of green colour; urine paler, reddens litmus; heat gives no precipitate.

Repetantur Pulveres et Mistura, et applicentur hirudines tres præcordiis.

18th.—Patient is easier, less pain in region of heart, palpitation further reduced, pulse 112, complains of pain in the nape of neck and in right wrist, aggravated by motion. He cries with the pain of wrist, when he exerts that part, as in endeavouring to sit up in bed. Several green stools; urine pale, deposits lithate of ammonia, reddens litmus; specific gravity 1020; neither heat nor nitric acid gives precipitate of albumen.

Repetantur Mistura et Pulveres Calomelanos. Capiat Unguenti Hydrargyri Fortioris, grana quinque, bis in die. Applicetur Unguentum Hydrargyri Fortioris præcordiis.

19th.—No pain in region of heart; palpitations further reduced; pulse 100.

Repetantur Mist. Pulveres, et Unguentum Hydrargyri et interne et externe. Applicetur Empl. Lyttæ præcordiis.

20th.—Pulse 100; no pain in region of heart; countenance placid; appetite returning.

Repetantur Medicamenta.

22d.—Is sitting up in bed; scarcely any pain in nape of neck or wrist; complains of teeth being very painful, but the gums are not swollen. No rubbing or bellows sound to be heard.

Sumat. Misturam Rhei et Magnesiae, cum opus sit pro alvo laxanda.

After the lapse of ten days, during which the patient had been sitting up out of bed, he became the subject of anasarca with albuminaria, in the course of which several circumstances of interest were noted, but which need not be mentioned here. It will suffice to say, that under the use of gentian and spirits of nitrous æther, together with

the warm-bath and wine, the swelling rapidly disappeared, and the urine became perfectly healthy. At the present time (18th Dec.), the patient is strong, runs about the house, and is rapidly regaining his florid colour. The heart's action is still, however, abnormally increased to a slight extent.

I deem it of importance to mention that the patient was visited at my request by my friend Mr. Dalton, of the Northern Dispensary, a few days after the onset of pericarditis, and that he was fully satisfied of the heart having been the seat of active inflammation within the few preceding days. There is one point of interest in this case which may be here mentioned with advantage; the patient frequently felt faint during the course of the anasarca, and the pulse of the right wrist would frequently become imperceptible, that at the left continuing perceptible, but very weak. The other remarkable features in this case shall be laid before the profession ere long, together with the histories of several other interesting cases of anasarca following scarlatina, which it is believed will throw some new and valuable light on the pathology of the disease, and lead to a more discriminating treatment of this sequela of scarlatina.

With a view to remove all reasonable doubt on the minds of any one respecting the morbid condition of the heart, it was determined to submit the patient to an eminent stethoscopist. Dr. Taylor, of Keppel Street, was good enough to examine him, and the following is his report. The examination took place on the 30th December. "Pulse at right wrist smaller and weaker than at left; impulse of heart too strong, heaving, and felt over a considerably larger space than natural; sounds of heart healthy, with perhaps a trace of murmur below nipple; dulness over heart extends to upper border of fourth rib, and extends transversely two inches; apex of heart beats between fifth and sixth ribs. There is moderate hypertrophy. Respiratory sounds healthy.

CASE III.—27th Dec. 1844.—John Jones, æt. 9, well grown, of previous good health, in comfortable circumstances, was seized with scarlatina nine weeks ago. The eruption was general, and remained out two or three days; the throat was affected to a slight extent only. The patient complained of pain in chest, and "thumping and knocking" of the heart during the period of the eruption. At the same time he suffered severe pains all over the body, but particularly in the ankles, which appeared to the mother slightly swollen. The urine was scanty, and caused pain when voided. The medical attendant said that the boy was suffering from pleurisy, and applied leeches to the chest. The patient improved, but in the course of a few

days he was again seized with what was called a pleuritic attack, when he was again treated by leeching. From this he made an incomplete recovery, and has been ailing more or less ever since; the "thumping" of heart still continuing, with occasional pain. Such is the report of the mother and of the patient.

At present, the face is decidedly of a livid hue; the expression is anxious and timid; the pulse is feeble, 100 per minute, weaker and smaller at right wrist than at left. The impulse of heart is increased both in force and in extent; it lifts the hand and the stethoscope: there is no bellows sound, nor can any rubbing be heard. The patient starts much during sleep; tongue clean; bowels open; appetite good. The external jugular veins are unduly distended, and the patient lies on his right side. Urine is plentiful, of a light amber colour; specific gravity 1025; heat and nitric acid give no precipitate; reddens litmus paper. Slight counter-irritation was applied, and a mixture of Tincture of Hyoscyamus and Sesqui-carbonate of Soda was ordered; a few doses of Hydrargyrum c. Creta were also prescribed. He improved considerably under this treatment, and the impulse of heart abated considerably. On the 30th December, at our request, Dr. Taylor examined the patient. No doubt of the heart being diseased, certainly not to a great extent, was entertained, yet it was deemed advisable to request the opinion of another physician. The following is his report:—"Face and lips somewhat livid; impulse of heart perhaps slightly increased in force and in extent; sounds of heart healthy; less vesicular respiration in left than in right lung inferiorly; percussion duller on left side; both sides measure alike from spine to sternum; vocal resonance much the same on both sides; pulse at right wrist is weaker than at left wrist.

12th Jan.—The patient has for the last few days taken a mixture of iodide of iron. He is now stronger, and experiences no pain in the region of the heart. On placing him before the window, the left mammary region is seen to be more prominent than the right, and the action of the heart is seen to move the soft parts more than natural. A line drawn from the middle of the sternum to the left nipple is a quarter of an inch longer than a line drawn from the same point to the right nipple.

From the occurrence of two unequivocal cases of pericarditis, and of a third of perhaps a doubtful character, in the practice of one physician, in the course of a few months, it appears reasonable to conclude that this complication is by no means rare.

The comparative infrequency of its detection is not conclusive evidence against the foregoing supposition. Many circumstances conspire to render it possible that the com-

plication may have been overlooked. Scarlatina is a disease of children, and it must be admitted, that their maladies, at least in this country, have not received that large measure of attention which has been accorded to the diseases of adults. Children are rarely admitted into the great hospitals of this country, where disease is, in a pre-eminent manner, most amply investigated, by the highest order of physicians. It is consistent with fact, to say, that the vast majority of scarlatina cases fall into the hands of gentlemen in general practice, whose extensive engagements preclude for the most part their paying very great attention to the less striking features of disease, and almost preclude the possibility of making post-mortem examinations. Further, the detection of pericarditis is attended with considerable difficulty. Rilliet and Barthez point this out in the following passage. "*Les symptômes de la péricardite ne sont pas faciles à constater chez les enfants. Le peu d'abondance des produits pleurétiques, la coïncidence d'autres affections graves, qui détournent l'attention de l'observateur, ou masquent les principaux phénomènes, l'absence de la douleur, ou la difficulté que l'on éprouve à la constater, l'agitation, l'anxiété des petits malades, qui empêchent quelquefois l'application de l'oreille à la partie antérieure du thorax, sont autant de causes qui s'opposent à ce que l'on puisse reconnaître facilement la pleurésie.*"—p. 205.

It is by no means improbable that not a few cases of organic alteration of heart, even in adults, may owe their origin to scarlatina which had occurred during infancy or childhood. The attack of pericarditis may have been altogether overlooked, and the chronic disease to which it has given rise may not have attained to such a height as to excite the attention of the patient himself, until many years have rolled past. Further, recent experience seems to show, that pericarditis is perhaps occasionally not incapable of spontaneous cure, and it is just possible that this complication may arise and disappear without the occurrence ever being suspected. We would warn, however, the practitioner against supineness under this view of spontaneous recovery. He must act as if he felt he had an ever active and dangerous enemy to contend against. *Ανακτος καθέυδοντος οί λαοί φράττονται.*

Again, it is worthy of notice, in connection with the question of the frequency of pericarditis as a complication of scarlatina, that it is only of late years that this affection has been noticed, during which time disease has been subjected to a narrow and strict scrutiny by instructed eyes, which was formerly almost unknown in any department of medical science.

It is anticipated that diligent inquiry will

not unfrequently succeed in detecting this complication for the future, and it is highly important that so momentous a complication be early discovered, in order that it may be speedily put down.

These objects, viz. an early discovery of the complication and a speedy extinction of the evil, will meet with much impediment if the profession be only partially informed on the subject, or if there be permitted to prevail an idea that the complication is only of very rare occurrence: Puchelt has aptly expressed the danger from this source. "*Nihil autem magis diagnosi juste verreeque obest quam preconcepta de raritate morbi ejusdam sententia; qui enim rarissimus habetur morbus raro quoque venit in mentem medici, et ubi adest aut omnino non, aut justo serius cognoscitur.*"—*De Cardidite Infantum Commentarius.*

Period of accession of pericarditis.—It is impossible to say positively at what period of the exanthem the affection of the heart supervened in the first case, for its presence was not suspected till the child was dying. But from the appearance which the heart presents, it is probable that the disease had existed at an early period. In the second case, the symptoms of pericarditis were strongly manifested on the seventh day of the exanthem, and two days after the disappearance of the eruption. In the third case, the knocking of the heart, and pain in the region of that organ, took place during the period of the eruption. Thus in two of these three cases the pericarditic inflammation took place during the first few days of the illness, and it is not at all improbable that such was the case also with the other.

Character of the scarlet fever.—In all the three cases there was what might be called considerable inflammatory fever; the eruption was vivid, and remained out the usual time. The fauces in all the cases were more or less inflamed and swollen. The urine, in the case of the boy Cook, was scanty and high coloured before pericarditis supervened; in the case of the boy Jones, the urine is said to have been scanty and high-coloured during the eruption. In the other case, viz. that which terminated fatally, the urine is reported to have been blood-red and scanty from an early period of the disease. Latterly it contained no albumen.

The mucous membranes are reported to have been unusually red in the case which terminated fatally; in the case of the boy Cook; the tongue was red with elevated papillæ; in that of the boy Jones the condition is unknown. Anarsaca of a very decided character showed itself in the cases of J. S. and the boy Cook, the swelling being general: in the third case, that of the boy Jones, it is reported by the mother that the face was swollen some time after the eruption. The

skin was very dry and desquamated freely in the fatal case, and in that of the boy Cook.

Painful affections of the joints occurred in the cases of Cook and Jones: the boy Cook suffered much in the nape of the neck and in the right wrist; Jones experienced pain all over the body, but particularly in the ankles. It is uncertain whether arthritic pains were experienced in the fatal case, but the patient, from a very early period of the disease, cried much whenever he was handled.

No information whatever is given of the character of the scarlatina in the cases complicated with pericarditis, by any of the writers who have noticed this complication. Rilliet and Barthez, Burrows, Copland, Joy, and others, are alike silent on this important point, at least so far as we have been enabled to ascertain. But Dr. Willis has informed us, that all, or nearly all the cases in which post-mortem signs of pericarditis were found, had been conjoined with anasarca.

In a case of carditis related by Krukenbergius which followed scarlatina—"cutis erat sicca, squaïda, non adco calida, urina parca et turbida sanguinem in se continere videbatur. Aliquot diebus præterlapsis facies turget."

It is worthy of notice, that all the patients were males, and under ten years of age.

Causes of pericarditic complication.—From a careful consideration of the particulars of the three cases above related, and of the pathology of scarlet fever, it appears reasonable to conclude that pericarditis, when it occurs as a complication of this exanthem, may owe its origin to two different sources, viz. the presence of the specific poison in the blood, acting as a local irritant, and extending throughout all the membranes and tissues of the body, and the presence of crystallizable compounds in the blood which should have been eliminated from the system by means of the kidneys, but which in consequence of disease of these emunctories are not unfrequently retained in the circulation.

With regard to pericarditis arising from the presence of the specific poisons in the blood, it may be stated that it is analogous to local inflammations which are wont to complicate continued fever, small-pox, and measles, during the first few days of their career. Arising in this manner, pericarditis may be expected to occur at an early period of the disease, *i. e.* during the eruption, or at the time it should appear.

So long ago as 1806, Dr. Wells said,—“Possibly the inflammation of the internal membranes, if it ever does exist, may be similar to that which occurs in the skin during the original fever.”

That pericarditis should occur in the course of, or subsequent to scarlatina, is not surprising. It is well ascertained that pericar-

ditis is liable to follow obstructive disease of the kidneys, and it is further familiar to all, that obstructive disease of the kidney is not uncommon during the convalescent period of scarlet fever. It would indeed be difficult to explain the circumstance, did pericarditis not occur under circumstances known to be productive of inflammation of other serous membranes. While we are not prepared to say that the three cases which have been related did not owe their origin to the first mentioned source, viz. the presence of the specific poison in the blood, we are much disposed to think, that in all the cases, but particularly in the fatal case, and in the case of the boy Cook, the complication was intimately connected with disorder of the kidney. In both of these cases extensive anasarca followed; and in the other case, the mother reported that the face of the patient was decidedly swollen, and that the urine was scanty and of high colour.

But in the cases of Jones and Cook, it may be objected to this view, that the affection of the heart preceded the disorder of the kidney. Now certain facts which have come to our knowledge, but which need not be detailed at length here, have demonstrated the fact, that the kidney is liable to be materially disordered within the first few days of the exanthem. The secretion of the kidney is diminished, and its chemical characters are altered. The appearance too of the kidney is also morbid, as we have had an opportunity afforded us of ascertaining. Yet, notwithstanding these conditions, the urine has not contained albumen, which we are disposed to believe is passed only some time after the kidney affection has become established, at least in some instances.

Nor is it unreasonable to suppose, that the kidney may become disordered at an early period, and thus lead to pericarditis and inflammation of other serous membranes. That organ is one of the chief emunctories of the body, and it is notorious that almost all the emunctories of the body are early implicated in scarlet fever—witness the skin, and mucous membranes.

The occurrence of affections simulating rheumatism forms, perhaps, further testimony of an early implication of the kidney. It seems probable enough, that these affections, like rheumatism and gout, depend upon the presence of crystallizable compounds either formed in excess, or not duly removed by the kidneys.

Treatment.—This may be resolved into preventive and curative. Preventive treatment must comprise means which will moderate the violence of the exanthem without unduly depressing the powers of the system, and rather direct the fury of the storm to the skin than to the internal organs. The curative treatment must be guided by

those principles which regulate the management of inflammation of other serous membranes. The importance of the heart must rouse to activity. But it will be the duty of the physician to keep in mind the storm through which the patient has passed, or must necessarily pass, and avoid unduly expending the powers of the system. General bleeding must be moderate when adopted, and employed only when the patient is still possessed of some considerable strength. Leeches and mercury, followed by counter-irritation, will be necessary. As a general rule, it would be prudent to avoid blisters and oil of turpentine, as counter-irritants, on account of the kidney. When the disease is connected with disorder of the kidney, which will be the case in most of the instances, that emunctory must be promptly treated. In the first place, it must be relieved by the local abstraction of blood (strength permitting), by warm bathing and purgatives, when not counter-indicated by diarrhoea, or irritable condition of the mucous membrane. As it is time to conclude, further notice of positive treatment must be omitted. One word on negative treatment. Every measure and every circumstance must be carefully avoided which would determine to the heart and kidney, and this rule should be observed whether our treatment be preventive, or whether it be curative. Further experience will probably prove that saline purgatives should be avoided when the kidney is diseased. The celebrated axiom of Sydenham, used in a modified sense, applied to the cold affusion of Dr. Currie in scarlet fever, will form an appropriate termination to our remarks on the treatment of pericarditis in connection with scarlatina—

"Eger non raro nulla alia de causa, quam iuniorum medicum diligentia ad plures migrat."

London, Feb. 1845.

OBSERVATIONS ON THE NATURE AND TREATMENT OF THE MORE IMPORTANT DISEASES OF THE NERVOUS SYSTEM:

With Illustrative Cases.

By EDWARD BLACKMORE, M.D. Edinb.
Member Extraordinary of the Royal Medical
Society of Edinburgh, and Physician to
the Bath Penitentiary.

[Continued from page 638.]

CASE XXII.—A master mariner, aged 45, of a spare habit, while violently exerting his voice in August

1827, was affected with a sudden loss of speech for an hour, after which weakness of the limbs supervened. He then recovered for some months; but in April 1828, was affected with stuttering and a tremulous tongue. On May 27th, I saw him, complaining of vertigo and loss of memory, and weakness of the right leg: pulse tense; tongue furred; purgatives, blisters, and low diet, used for a week with much amendment. Then, on taking wine and eating heartily, he got severe pain at the right temple, with vertigo, and vomiting; the pulse was contracted.

Leeches, blisters, and purgatives.

In a short time he became as well as before the attack in April, except that slight causes would induce headache.

Purgatives continued.

July 17th.—At noon, a pain in the forehead, and temporary loss of speech.

Leeches and purgatives.

Then a tingling in the arms, confusion of the mind, and fulness in the head, but the pulse weak; blisters relieved him a little, but the speech continued affected, and the disease passed into mania.

CASE XXIII.—A man, aged 42, was affected in August 1828, with spasms of the lower limbs, palsy of the left leg, incontinence of urine, and an irregular state of the bowels: these symptoms were relieved for a time by blisters, liniments, and aperients; but in November 1829, he again came under my care, for long continued pain in the rectum, impeding walking, a sense of sleepiness and coldness in the thighs, and inability of bending them on the pelvis, and obstinate costiveness; his gait in walking was that of one in incomplete paraplegia: he had no head symptoms. Blisters, issues, and leeches on the loins, had been used with no benefit; he suspected a disease in the rectum, but none could be found on examination.

Cupping in the loins, and the turpentine liniment: blue pill; camphor $2\frac{1}{2}$ grains, thrice a day; and oily clysters.

By these means, he felt better in a fortnight; when, as he thought, the pain in the arms, and costiveness, was the cause of his inability to walk, (for

that eight months previously, on this being relieved, he could walk two miles!) Copaiba was given, with purgatives.

Dec. 10th.—Relief.

18th.—The gut irritated by the medicine.

22d.—The palsy remaining; half a grain of the powder of *nux vomica* was ordered every night.

25th.—A sense of “searching” in the rectum, and a discharge of flatus; the power of walking improved.

Medicine continued; and clysters of croton and olive oil.

27th.—A gentle aperient effect from the clyster; pain at sacrum, and twitching of the legs. In a few days, the nux was exchanged for strychnia, one-sixth of a grain thrice a day.

February 6th.—More power of the legs, preceded by more twitching, and the clysters act better.

10th.—Clysters discontinued, strychnia repeated, a third of a grain at a dose; the next seven days the benefit was continued; on the 17th, the strychnia was stopped, and clysters resumed, for pain in the back, and costiveness: afterwards croton oil was given every morning, and half a grain of strychnia twice a day to the 24th, with great relief: a scruple of strychnia was taken in a month. The heat and muscular power of the limbs remained better to March 10th, but the bowels still required aid, and castor oil answered best; the stools being then very deficient in bile, blue pill was added to the purgatives with considerable effect, the purging always being felt useful to the end of the month, when strychnia was again resumed: but it was soon dropped, as it seemed to make a feverish tongue; and castor oil, with liquor potassæ, was also continued to the middle of April, when being better, but not well, the medicine was discontinued.

CASE XXIV.—A lady, about 46 years of age, had influenza, in February 1837, after which she observed that her left arm and leg began to tremble, but without loss of feeling or of muscular power. At the end of a year she came under my care; the affected limbs cold and discoloured, but not feeling cold to herself; the bowels torpid; sleep lethargic; tremors constant, in-

creased in straining at stool, and relieved on piles discharging; pulse weak; menstrua regular; habits sedentary, and two glasses of wine taken daily.

Regulated diet; one glass of wine only, taken at noon; walking exercise in dry weather; compound decoction of aloes, and pills of colocynth, blue pill, and camphor; friction of the limbs with a hot flannel and hot salt.

This treatment relieved the bowels of an immense load of fæces, and was followed by considerable amendment in six weeks; but not by complete recovery.

CASE XXV.—A lady, beyond 40 years of age, had long been subject to severe rheumatic neuralgia of the shoulders and lower limbs, for which hot mineral baths had been tried unsuccessfully. The douche on the sacrum in her pregnancy had induced abortion with profuse hæmorrhage. For the general debility and semi-paralytic state of the legs, she had taken much quinine and the gum resins before coming under my care: at this time, she was nearly a cripple, the bowels lax, and the constitution debilitated. Her recovery was complete in the course of six months, after taking at first, Plummer's pill with rhubarb, decoction of *sarsaparilla* comp. with lime water, and iodide of potassium to a large quantity, after strychnia had been used in vain. The only local application was a tight flannel roller.

Section III.—ON HYDROCEPHALUS.

This disease presents some interesting varieties in its external form, whether occurring as a primary or a secondary affection.

(1.) Primary: *e. g.* (a) the leading symptoms—vomiting and costiveness, and pain in the head, inducing the idea that the bowels are the chief seat of disease, when a minute inquiry will discover some previous complaint of the head, with lassitude, drowsiness, and occasional vomiting. (b) A singularly obscure remittent form, in an adult, marked by a throbbing headache, with occasional vomiting, yet without sufficient illness to lay him up; then an aggravation of the symptoms; for which the usual treatment was used with relief, the pulse falling from 70 to

60; in three days an amendment, then a sudden relapse of agonising pain persisting for some hours and terminating in death without coma.

(c) In a boy five years old, the sutures, after having been firmly united, yielding to the distending force of the effusion, and becoming widely separated, and followed by an improvement in the coma and convulsions.

(d) The symptoms merely heaviness in the head and restlessness at night, slightly aggravated during dentition, yet inspection showing that at the very time serious organic disease was forming in the brain.

Experience will impress on every medical man the importance of directing attention to the head, whenever, in infants, shivering, lassitude, and fits of screaming occur, with either a depression of the circulation or febrile symptoms, without obvious disease in the chest or abdomen.

The relation of a particular group of symptoms to a particular seat in the brain, presents an interesting subject of inquiry: the same symptoms appear in many cases to be connected with different anatomical characters; such as vascularity, effusion of serum, and supuration; but the severity of the convulsions, and the early fatal termination of the case, has appeared to me to be often connected with disease of the medulla oblongata.

Convulsions generally accompany this disease in the young. In some very important cases in children, the early symptoms are those of depression of the nervous and vascular functions, as in idiopathic fever; the remittent character of which is apt to delude the attendant. The progress of such a case is often rapid; sometimes the vomiting subsides after the outset, and the bowels are soluble; the leading symptoms are delirium alternating with stupor; the vital powers then quickly failing, the pulse being simply frequent to the last.

In another variety the rise of the disease is very insidious and slow, marked by intermitting pain in the head, and vomiting occurring once or twice in a day; the illness not severe enough to prevent the child's continuing its school, or its play; yet at this very time a disease is subsisting that will be quickly fatal! An outburst of delirium is followed by irregularity of

the pulse, stupor, and death in a week from the first serious symptoms!

(2.) *Secondary Hydrocephalus.*

In a case of severe inflammation in the pericardium and diaphragm in the course of rheumatic fever, the first indication of disease in the head was high and persisting delirium. In another case, after two attacks of pulmonic inflammation at a short interval, the symptoms of a head affection were disturbed sleep, starting up in bed and shouting as if in a wild disease, but with no complaint of the head during the day: then loss of appetite, lassitude, wasting, for a fortnight: a cessation of all pulmonary symptoms on the head becoming affected: then vomiting, pain in the head, but not severe, for a few days; then, the first alarming symptom, the pulse suddenly becoming intermittent, attended with obstinate costiveness; then low vital powers, with hectic, convulsions, and the countenance and tongue as in synochus, and death on the sixteenth day from the acute attack.

Every practitioner has seen a severe threatening of the symptoms of hydrocephalus in connection with worms; the relation of the two conditions is probably not yet determined.

Cases occur of acute enteritis, which remits, and is followed by acute pain in the head, vomiting, and costiveness; yet little attention is directed to the real seat of the more important disease.

A most deceptive form of protracted encephalitis is met with, leading to organic disease; yet the symptoms, until shortly before death, are those of ileus! *e. g.* most urgent daily vomiting, with obstinate constipation for a month, yet the appetite unimpaired; no fever, no disturbance of the sleep, or of the mental faculties; the pulse nearly natural. The symptoms going on with slight remission for seven weeks; then an aggravation with febrile state, but the blood not inflamed; the bowels still appearing to be the chief seat of irritation: then coma, an irregular pulse, and death in a few days from the first unequivocal symptoms of a head affection.

The Prognosis.—In some cases, an unexpected but deceitful remission of alarming symptoms is seen, while collapse of the vital powers is going on: this exhaustion, however, is not

always fatal, if the pulse is not intermittent, and if the eye does not indicate pressure on the brain. Sometimes we see coma and convulsions subsiding, and general palsy remaining; the functions of organic life continuing for many weeks! Many severe symptoms, such as fever, convulsions, and coma, will remit, yet the dilated pupils and intermittent pulse show that incurable lesion is done to the brain. Sometimes, after a purgative, the pulse, which had been irregular, will become natural, yet the case will be hopeless.

Slight symptoms in these secondary cases should not encourage a too favourable prognosis. Sometimes death occurs in the midst of delirium, in the second week of the disease, without coma. In the slighter attacks, a remission of the more alarming symptoms is not to be too much depended on, while the tongue remains white and dry.

A cutaneous eruption supervening is a well-known favourable prognostic symptom.

The prognosis should indeed be always cautious; for, in many cases, at the moment that alarming symptoms set in, effusion has already begun. Irregularity of the pulse, continual tossing of the head, and a fixedness and dilatation of one pupil, are very bad symptoms; on the other hand, severe symptoms in a case protracted for two months, giving unequivocal evidence of effusion in the brain, have terminated in recovery. Sometimes, however, the utmost that medicine can do is to convert acute hydrocephalus into the chronic form, the inflammation, though controlled, going on to disorganise the brain, even when an improved state of the natural functions and of the nervous energies might seem to give a hope of convalescence.

The prognosis is to be founded on the severity and duration of the early symptoms, and on the treatment of the early state of the disease; for when this has been inadequate, there is little hope of recovery, although the alarming symptoms may for a time have remitted.

The blood not presenting the usual appearances of inflammation is a bad sign; as is the pulse becoming progressively more rapid and irregular: in one subject, fifteen years of age, it was as high as 206 shortly before death.

Convulsions, and especially tonic spasms in the latter stage, are generally hopeless.

Antecedent disease in any of the thoracic or abdominal viscera will give high importance to slight head symptoms.

Danger is not always announced by any particular set of symptoms: there is in some of the worst cases no vomiting, except at the outset of the disease, no costiveness, no screaming, no tossing of the head, no irregularity of the pulse; but delirium is succeeded by coma or convulsions, and rapid death. If one week has passed away, after decisive symptoms of inflammation, without adequate treatment, the case is often hopeless, whatever the symptoms may be in the second week of the disease.

Pathology of the disease.—In attempting to illustrate pathology by morbid anatomy, it is requisite to remember, that in the dead body the true condition of the organisation during life is not shown; the state of death itself, and the treatment before it, tending much to alter or to efface the natural anatomical characters.

Inflammation of any portion of the encephalon may give rise to the symptoms of hydrocephalus: there is no fixed relation of particular morbid changes to a particular group of symptoms; but inflammation at the summit of the hemisphere is characterized more by headache, delirium, and febrile symptoms, and inflammation at the base of the brain, by convulsions, and changes in the pupils and the pulse, and by rapid death, which occurs without profound coma. The seat of the inflammation is sometimes determined by the nature of the exciting cause: *e.g.* the medulla oblongata and the cerebellum have been especially inflamed after strong muscular exertion during exposure to the sun.

The scrofulous character of the inflammation is manifest; the disease often co-exists with scrofulous tubercles in other parts; and although this species of inflammation is most generally seen in weak constitutions, and exhibits a languid character, it is sometimes extremely acute, and rapidly induces intense congestion and serous effusion, suppuration, induration, softening, and ulceration. In some cases the disease is more of an erysipelatous

nature, extremely diffusive, and succeeding to external erysipelas; and most inadequately manifested in the state of the pulse and of the symptomatic fever.

Effusion into the ventricles is sometimes the direct effect of inflammation of the membrane lining these cavities; at other times, it is merely the effect of a determination of blood to the brain in general. This effusion is not always a sign that the morbid action was asthenic; the other morbid appearances (as well as the symptoms during life), such as a general enlargement of the arteries, diffused vascularity and fulness of blood, and firmness of the brain, prove that the disease is truly sthenic.

In an instance of acute inflammation which passed into a chronic state, supuration and inflammation of the inferior part of the brain was found in an infant five months old.

In a patient of a scrofulous family, in whom the disease advanced rapidly to its fatal issue in the second week, the pulse and fever did not adequately show the danger; the vomiting was little urgent, the bowels easily moved by medicine, and no convulsions had existed; yet there was found intense vascularity of the brain and its membranes, without much effusion.

In a case in which there was no screaming, no tossing of the head, no irregularity of the pulse, no vomiting, but lassitude succeeded by convulsions, delirium, and sinking of the vital powers, in the third week, we found marks of intense inflammation of the membrane, particularly about the tuber annulare, with much serous effusion. It was manifest here, that effusion had begun from the moment alarming symptoms had set in.

In a case where urgent vomiting and costiveness were for weeks the leading symptoms, to which at length coma was superadded, a scrofulous tumor was found in the inferior part of the cerebellum.

In one case, marked by intense but remitting pain in the head, without delirium, convulsions, or coma, an abscess was found in the hemisphere, with induration of the surrounding brain: yet there was an astonishing approach to convalescence while the supuration was going on. In another case we found extensive softening of the central and posterior parts of the hemi-

sphere, serous effusion, enlarged arteries, the membranes intensely vascular; the disease connected with scrofulous tubercles in the lungs: the symptoms at first obscure, slow in their progress, and finally resembling those of fever. In one case, sudden lethargy and syncope, preceded by torpor of the liver, appeared to arise from sanguineous congestion in the whole encephalon. In another case, slight marks of vascularity, and little serous effusion, were found in a cachectic state of the constitution in an adult, in whom headache, vertigo, confusion of thought, squinting, and convulsions, had indicated a very severe disease of the brain.

It is important to remember, that some of the symptoms of hydrocephalus, such as delirium, convulsions, and coma, do not always arise from the same condition of the organization; they may be really of a different nature in different cases, and at different periods of the same case; they are seen in an exhausted state of the system, as well as in a plethoric and inflammatory state of it; they are at one time truly designated nervous symptoms, and at another, inflammatory. In states where they have not appeared to arise from pressure combined with increased momentum of the circulation, they have been usually attributed to anæmia of the encephalon; but it seems probable that a congestion, and slow or impeded circulation of the blood in the dilated vessels of the part, which involves a want of oxygenated blood, is the true proximate cause of these nervous symptoms.

[To be continued.]

ON THE ERGOTIZATION OF THE TIPULIDÆ BY HYDROCYANIC ACID.

To the Editor of the Medical Gazette.

SIR,

A COMMUNICATION appeared, some time since, in the Dublin Journal of Medical and Chemical Science, from the pen of Dr. Scanlan, in which it was stated as an important practical fact, in reference to the effects of prussic acid on the animal economy, that it "*ergotizes the tipula, promoting parturition by strong convulsive efforts!*" Subsequently, the parturient exciting powers of this agent were gravely commented on by

the learned translator of Majendie's "Formulary," as a "curious truth," which had been ascertained beyond the shadow of a doubt.

We cannot well comprehend the nature of the inductive process which led to the experiment on the ill-starred tipula: nevertheless, it stands upon the record, and affords an example for one of those hasty generalizations in which many inquiring minds are prone to indulge, and which, in every age, have so seriously obstructed the progress of scientific truth.

The female tipula, or crane-fly, is provided with an ovipositor, consisting of a sort of pincers, or forceps, of a horny consistence, and sharp at the point. By gentle pressure, the eggs, which are extremely minute and black, like the grains of gunpowder, may be easily extruded. These eggs lie at the extremity of the abdomen, surrounded by strong symmetrical horizontal bands of muscular fibre, and so intense is the instinct implanted by the God of Nature in these creatures, to expel their eggs at the proper season, that it becomes a mechanical operation, which nothing but the death of the insect can prevent. If the abdomen be severed from the thorax by dividing the abdomino-thoracic articulation, the work will still proceed uninterruptedly. I once watched a mutilated female crane-fly, in the season of egg-laying; its head and thorax had been accidentally completely crushed upon the spot on which it had alighted; the abdomen being uninjured, alone preserved its vitality; still the process of depositing eggs continued as vigorously, though not, perhaps, so systematically, as if the insect had been perfectly entire. The same is recorded of the whole family. The *Cecidomyia Tritici*, of Kirby, deposits its eggs with such intensity that it may be readily taken, and when placed in a situation where its operations are perpetually interrupted, will continue its labour. This was observed by Mr. Shireff, an intelligent naturalist of East Lothian, who put a fly then laying between the face and glass of a watch, where it deposited its eggs, though its limbs were invariably entangled by the revolving moment-hand.

It is almost ridiculous, therefore, to deduce this new property of prussic acid from such an experiment as that of Dr. Seanlan; and we should be equally

justified in concluding that severing the head from the body, crushing the thorax, or otherwise mutilating the tipulidæ, are ergotizing agents, because the vitality of the abdomen not being destroyed, they do not interrupt the process of ovipositing.—I am, sir,

Your obedient servant,

R. H. ALLNATT, M.D.

Parliament Street, Whitehall,
Feb. 15, 1845.

EFFECTS OF THE CYANIDES.

NO III. CYANIDE OF SILVER.

To the Editor of the Medical Gazette.

SIR,

THE three accompanying cases, which have been casually taken from a great many, will indicate the poisonous properties of cyanide of silver.

It might, at first, be supposed from the insolubility of this salt, that little or no poisonous action would result from its entrance into the system, and my earlier experiments seemed almost to bear out this supposition, for when the compound, previously well dried, was introduced either into the stomach or peritoneal cavity of a healthy animal, no ill effects of any consequence were produced, if I except that when it was given by the mouth, it invariably produced vomiting and its own ejection; but, on pursuing these inquiries, I soon found that very different results were manifested when the cyanide of silver was administered in a moist state, just as it is precipitated, care having always been taken to free it entirely from every soluble compound; it then entered the circulation with facility, and proved a violent poison: for instance—

Exp. I.—Six grs. of cyanide of potassium were dissolved in water, and completely precipitated by a slight excess of nitrate of silver. This would form about 10 grs. of cyanide of silver, which, after being well washed, were given mixed with food to a young mongrel terrier; in ten minutes, the animal began to vomit, and soon the food, together with the cyanide, were ejected. The vomiting, however, still continued, and it threw up a quantity of thick mucus; in thirteen minutes, the dog lay down, apparently exhausted, and was much disturbed by the continued retching; in the course of a few mi-

minutes this subsided, and after the lapse of one hour the animal appeared to be perfectly restored and well. At this time, when its stomach was completely empty, 10 grs. more of the cyanide were administered; in two minutes it began to stagger, then fell, and was slightly convulsed, the head being drawn back, and its limbs extended; in half a minute more the convulsion became violent, the dog uttered loud cries, its respiration became difficult, and the action of the heart fluttering and irregular; in three minutes it threw up about an ounce of a thick mucus, without odour, but suspending the white cyanide of silver; from this time, the animal lay deprived of all voluntary motion, the sphincters of bladder and rectum became relaxed, and the action of the heart more and more tumultuous, fluttering, and beating with three or four rapid jerks at each inspiration; the breathing was also carried on with a peculiar sighing effort, the result of a sudden and deep inspiration; in fifteen minutes the eye had lost its sensibility, and could be touched without winking; after the lapse of half an hour the respirations had become fuller and easier, the heart's action more regular, and the eye had regained its sensibility, and I was led to believe that the animal would recover, but in another twenty minutes it again relapsed, had a few weak convulsions, and breathed with a moaning noise: from this time the respiratory efforts became slower and weaker, and at the expiration of three hours from the administration of the last dose, it died quietly, and without the least struggle.

The body was examined twenty-four hours afterwards. The pupils were much dilated; the vessels of the brain congested and full of black blood. The stomach contained about 2 oz. of a thick brown fluid, in which a little cyanide of silver still floated; it had a slight odour of prussic acid, was neutral to test paper, and gave ample evidence of the presence of both cyanogen and silver, by their appropriate reagents. The coats of the stomach were highly congested, and in many places the blood appeared extravasated. The lungs were collapsed, injected here and there in patches, so as to give them a mottled appearance; both sides of the heart were full, and the right gorged with black blood.

Exp. 2.—Five grains of moist, and similarly prepared cyanide of silver, were introduced into the peritoneal cavity of a small terrier; in four minutes it appeared uncomfortable, holding its nose to the ground, and going round and round as if it were about to lie down; in six minutes it lay as if it were tired or exhausted, but on being roused it got up and walked about. In fifteen minutes it lay stretched on the ground insensible, there having been no previous convulsion; but it had gradually become comatose, appearing to have slept off into this state; its breathing was now slow, and accompanied with a peculiar sighing and moaning noise. The eye was insensible to touch, the heart's action laborious, and in one hour, the respiration having become gradually slower and slower, it died without a single convulsion.

The body was opened the next day. The pupils were much dilated. The vessels of the brain full. The peritoneal cavity still contained a quantity of the white cyanide, and its walls appeared slightly congested. The right heart was full of coagulated black blood; the lungs collapsed and redder than natural.

Exp. 3.—Five grains of recently prepared cyanide of silver were injected into the jugular vein of a large bull terrier; instantly it began to cry and struggle violently, and on being released, it ran about uttering loud cries, as if it were in the greatest agony; in one minute it fell and was convulsed; the breathing became laborious, and in two minutes it was dead; a large quantity of clear fluid ran from its mouth, and this was followed by a white frothy liquid, both of which came from the lungs, for the trachea was full of it. On opening the chest the heart was found to be still fluttering, its right side gorged almost to bursting with black blood. The lungs had not collapsed, they looked paler than usual, and when cut into exuded the same white frothy liquid streaked with blood.

The question in this last case was, whether the effects had resulted from any specific agency of the cyanide, or whether they were merely due to its mechanical action in stopping the capillaries of the lungs; and to determine this five grains of chloride of silver were thrown into the jugular vein of

another dog; in both instances the greatest care was taken to exclude all air from the apparatus; in three minutes the animal fell, making great efforts to respire; these became still more energetic during the next minute, when it began to cry, but not loudly. No pulsation of the heart could be felt, notwithstanding the continuance of the respiratory acts, and in another minute it was dead. On opening the chest, the heart, as in the previous case, was still fluttering; its left side contained a little fluid blood, but its right as well as both cavæ were gorged. The lungs were paler than natural, had not collapsed, and when cut into they shrunk and exuded a little frothy fluid; but there was none of this in the larger bronchi or the trachea. Both of these experiments were repeated, in order to be certain of the results, and the conclusion was, that the cyanide killed the quickest, and that it produced convulsions which were not seen in the other cases. The ultimate effects of both, however, appeared to be the stoppage of respiration by the production of a frothy fluid in the air-cells and smaller bronchi.

Conclusions.—From all these experiments it appears that cyanide of silver acts as a local irritant, producing great vomiting and a congested state of the vessels of the stomach; that when it has been dried before its introduction into the system no other ill effects follow; but if it is administered in a moist state, it is then capable of becoming absorbed, and perhaps decomposed, for an albuminous solution has the property of dissolving the cyanide, and moreover the contact of it with any of the chlorides of the systemic fluids would produce a double decomposition, and the formation of a soluble cyanide, whose effects would be similar to that of cyanide of potassium.

The dose which is capable of killing a dog is five grains; its specific action seems to be on the brain, producing occasional convulsions, always coma, paralysis, a peculiar sighing respiration, a fluttering, irregular, and tumultuous action of the heart, and it ultimately kills by a gradual exhaustion of the involuntary acts, death taking place in from one to three hours after its administration.

The *post-mortem appearances* are a dilated pupil; an injected state of the vessels of the brain; the heart gorged and full of black blood, especially on its

right side; and when the poison has been administered by the stomach, that organ is exceedingly congested, completely emptied of solid matters, and may smell slightly of prussic acid; but there is no difficulty in detecting chemically the presence of both cyanogen and silver.—I am, sir,

Your obedient servant,

H. LETHEBY, M.B.

Lecturer on Chemistry at the Medical School of the London Hospital.

12, Tredegar Square, Feb. 17, 1845.

ANALYSES AND NOTICES OF BOOKS.

“L’auteur se tue à allonger ce que le lecteur se tue à abrégé.”—D’ALEMBERT.

Outlines of Chemistry, for the use of Students. By WILLIAM GREGORY, M.D. Professor of Chemistry in the University of Edinburgh. With numerous engravings on Wood. Part I.—*Inorganic Chemistry.* Taylor and Walton. 1845.

WE congratulate the Edinburgh School of Medicine and Philosophy on the appearance of this ably compiled, unambitious little volume, as an earnest of the resuscitation about to be effected in the vital chemistry of that city, after half a century of torpor. The researches of the late Professor, Dr. Hope, on Strontites, which gained him his chair and his reputation, were made in the preceding century at Glasgow, and, as was well known to the Doctor’s friends in that city, were made with the ingenious but unacknowledged aid of Mr. John Laurie, the chemical operator in the great firm of Knox, Tennant, and Macintosh.

Though Dr. Gregory’s work is professedly designed for the perusal of students attending lectures on chemistry, yet we cannot agree with its modest author, that such is its exclusive use; for it exhibits in a compact and economical compass a lucid systematic detail of the leading facts of the chemistry of inorganic bodies.

The subjects of heat, light, electricity, and magnetism, are properly relinquished by our author to the writers on natural philosophy; by several of whom, especially in France and Germany, they have been treated with equal profundity and copiousness. In those cases where these imponderables come into close contact with chemistry,

Dr. Gregory has not neglected their mutual illustration; and he justly enjoin all his students to make themselves acquainted with the principles of physics.

There is one feature of the work, to which, in common with the author, we would direct attention. After describing chemical processes and changes, he adds a symbolical representation of the reaction in the form of an equation. This plan, so well fitted to simplify the comprehension of the metamorphosis, and to imprint it on the memory, has been generally adopted by Professor Gmelin, in his admirable *Handbuch*, now in progress of publication. Such equations, given in a few letters, serve also to guide experimenters in the proportions required for laboratory operations. We are inclined to think that he might also have imitated the learned Professor of Heidelberg, in his repudiation of the binary salt hypothesis, who states several facts evidently inconsistent with the notion that the salts hitherto regarded as consisting of an acid combined with an oxidised base, are composed of an acid, plus oxygen, combined with the metal itself; and that, accordingly, hydrogen, and not oxygen, is in all cases the acidifying principle. In the present state of our knowledge we do not see any practical advantage in this hypothetical representation of the acid and saline bodies.

In the first portion of the Outlines, the doctrines of the elements, combustion, decomposition, and definite proportions, are well discussed. Under the head of Atomic Theory, there is a succinct account of chemical symbols, equations, and formulæ; as also combinations by volumes. We have next a distinct statement of the somewhat intricate subjects of isomorphism and isomerism. He then proceeds to the details of the simple bodies, which, after the late fashion of compilers, he groups under two classes of metalloids and metals. Now Dr. Gregory, who is a classical scholar, as well as a chemist, knows that the affix *oid*, from the Greek word *ειδος*, signifies *form* or *state*; and surely neither oxygen nor nitrogen betray anything metallic in their nature or aspect. Even chlorine, one of the most condensable of the gaseous "metalloids," shows no metallic appearance under the intense solidifying power, recently applied to it, in the admirable

researches of Professor Faraday. Hydrogen alone might with some plausibility be styled a metalloid, since it forms with the elements of ammonia an alloy possessed of metallic properties.

The section on symbols and formulæ, equations and their uses, will prove to the student a most valuable part of the book; enabling him to pursue the complex investigations of Liebig, Berzelius, Dumas, &c. through every atomic permutation.

As one example of our author's luminous manner of writing, we insert the following paragraph from the article Hydrogen, p. 52.

"In relation to acids, therefore, water acts the part of a base; in relation to bases, that of an acid; and in relation to neutral salts, that of a neutral or indifferent substance, or, indeed, of a neutral salt. Taking the three examples of hydrated sulphuric acid, HO , SO_3 , hydrate of potash, KO , HO , and dry sulphate of iron, FeO , SO_3 , + HO , it is to be observed that the water in the first can only be replaced by a base, such as potash, KO , which would yield sulphate of potash, KO , SO_3 ; the water in the second can only be replaced by an acid, such as sulphuric SO_3 , which would yield the same salt, KO , SO_3 ; and the water in the third may be replaced by a neutral salt, such as sulphate of potash, KO , SO_3 , which would give rise to the double salt, FeO , SO_3 + KO , SO_3 . Water in these three different characters is called basic water, hydratic water, and saline water, and, in addition to these, we have water of crystallisation."

In treating of the analysis of atmospheric air by explosion with hydrogen, Dr. Gregory has committed a curious oversight, which will perplex most readers. He has given, with his usual neatness, a figure of Ure's modification of the eudiometer of Volta, but has described the apparatus and manner of using it as if it were Volta's upright glass tube, from which, as is well known, by the sudden expansion, an unknown proportion of the gases is apt to be ejected, so as to render the result fallacious. Ure's syphon eudiometer obviates this evil; for when the electric spark is made to pass between the two points of the platinum wires, near the sealed end of the glass syphon, this is not inverted in either water or mercury, as Dr. G.'s description leads one

to suppose, but is removed from the pneumatic trough, and applied with the hand to the electric machine as the woodcut shows it, while the open end of the syphon-tube is closed with the point of the finger. The expansion of the exploding gas in the sealed leg of the syphon cannot now cause any discharge of gas, but merely a momentary compression of the atmospheric air in the space between the finger and the surface of the mercury, and this recoil upon an elastic fluid prevents the glass from being broken by the most violent explosions, even of olefiant gas with oxygen.

From Dr. Gregory's figure of the apparatus for distilling phosphorus from the usual mixture of acid phosphate of lime and charcoal, we surmise that he has never performed that troublesome operation upon any scale, for he represents the neck of his retort, and its prolongation tube, both in a horizontal position, whereby he would soon find them to become so obstructed by the condensed product as to cause the retort to burst. The neck of the retort should, on the contrary, be inclined downwards at an angle of nearly 45° , and its beak be directly dipped just beneath the surface of water in a basin. Even under this disposition for favouring the running down of the liquified phosphorus, the neck of the retort sometimes needs to be made pervious by placing a hot iron or cinders under it. At page 110, a clerical error occurs which may puzzle students. "When no more phosphate of lime is formed, the whole is digested with cold alcohol, and the clear solution allowed to stand as long as it deposits crystals of phosphate of magnesia." As no magnesia is present, it is impossible to imagine how crystals of its phosphate can be produced.

Our author describes, with habitual precision, the usual process for preparing sulphuret of carbon; but in referring to that form of a condenser tube in which cold water is made to flow upwards between it, and its tubular case, he calls this useful contrivance Liebig's condenser; not being aware that it was invented and made the subject of a patent in this country nearly thirty years ago, by Taylor and Martineau; and was by them mounted upon a great scale in the Apothecaries' Hall, and many other establishments. Liebig's

condenser is merely one member of that many legged zig-zag most compact and powerful refrigerator. It is probable, however, that the great chemist of Giessen knew nothing of Taylor and Martineau's plan when he constructed his condenser.

As a specimen of our author's happy talent for practical tuition, we quote his instructions for preparing pure hydrate of potash, an essential chemical reagent not a little troublesome to make in the common way.

"*Syn. Caustic Potash.* $\text{KO}, \text{HO} = 56.176$.—This important compound is best prepared by acting on pure carbonate of potash, dissolved in water, so as to deprive it of carbonic acid. Two parts of carbonate are dissolved in twenty of boiling water in an iron pot, and one part of quick lime, being previously slaked by covering it with boiling water, so as to form a kind of cream of slaked lime, is added to the boiling liquid in small portions, the mixture being allowed to boil a minute or two after each addition. When all the lime has been added, the whole is to be boiled for five minutes, care being taken to keep up the original quantity of water; since, with less water, the potash actually takes back the carbonic acid from the lime. The vessel, which ought to be more deep than wide, is then covered up with its lid, and allowed to stand for 24 hours. At the end of that time, if the above directions have been exactly followed, $\frac{2}{3}$ of the liquid may be decanted off perfectly clear and colourless. This is a pure solution of potash, and to obtain the hydrate we have merely to boil it rapidly down, in a clean deep iron or silver vessel, till the residue flows like oil. It is then poured out on a plate of silver, and, on cooling, broken up into fragments, and preserved in well-stopped bottles."

Under arsenic, he details at length the elaborate processes of Fresenius and Babo; and recommends the often prescribed antidote of hydrated peroxide of iron; which we fear will prove an utterly abortive means of neutralizing solid particles of arsenious acid in contact with the coats of the stomach. For the detection of the poison and measurement of its quantity, in any liquid, the committee appointed by the Prussian Government have recently contrived an exceedingly neat apparatus, which deserves to be gene-

rally known to medical men, and which we shall describe in a simplified form in the next number of the *GAZETTE*.

We take leave for the present of Dr. Gregory, impressed with a deep sense of the obligations which he has conferred on the study of chemistry in this country by the publication of his *Outlines*; and we look with anticipations of increased pleasure for the appearance, promised in spring, of the second part of his work, on *Organic Chemistry*; a department in which he has become no mean adept, under his celebrated German master. Medical practitioners, who wish to bring up their arrears of chemical knowledge, cannot do better than make themselves familiar with Dr. Gregory's work.

Contributions towards a Fauna and Flora of the County of Cork; the Vertebrata by DR. HARVEY, the *Mollusca*, &c. by J. D. HUMPHREYS, the *Flora* by DR. POWER. London: Van Voorst. 8vo. pp. 130.

THIS slender volume comprises a set of elaborate catalogues, forming part of a series of communications on the local history of the county of Cork, which have from time to time been contributed to the Cuvierian Society of that city. It is calculated to be a useful guide-book to naturalists who may explore the above district of Ireland. Its authors deserve great credit for the ability displayed in collecting and arranging the amount of scientific information it contains; for it is by no means an easy task to compile a work of the kind.

MEDICAL GAZETTE.

Friday, February 21, 1815.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

THE QUESTION OF MEDICINE STAMPS.

It has been repeatedly urged in many of the petitions lately forwarded to Parliament, "that Government should not lend its sanction to empiricism, by granting patents for secret medicines."

We do not pretend to extenuate or deny the principle of quackery being thus ostensibly licensed; but we submit, with all deference, that the question is one of state finance, and with which, consequently, medical men have no proper right to interfere. In the year 1783, when the nation had been drained by a long and expensive war, it was found necessary to raise the sum of £650,000, in order to pay the interest of a loan of twelve millions sterling. Lord John Cavendish, the then Chancellor of the Exchequer, proposed, along with other things, quack medicines as very fit objects of taxation; and he believed that the House of Commons would be surprised at the amount which he had good grounds for anticipating would be thus realized, namely, £15,000 a year. It was accordingly provided, that "all persons who sold medicines, and who were not regularly bred to the profession of doctors," &c.* should take out a license; and this being done, there should be a duty of 8d. per cent. laid on the medicine. The love of being drugged, so conspicuous among the English, Lord John Cavendish foresaw might be turned to good account; and there he was right, for the tax has occasionally produced nearly treble of what was originally contemplated.

Having been at some pains investigating this matter, we are glad to perceive that the revenue derived from so disreputable a source has been gradually declining during late years, as the subjoined tabular statement, deduced from the most recent Parliamentary Returns, will shew:—

Medicine Stamps.

1831.....	£39,084
1832.....	44,379
1833.....	38,375
1834.....	31,007
1835.....	30,516
1836.....	31,376

* Parliamentary History for 1782-83.

1837.....	30,495
1838.....	29,422
1839.....	29,858
1840.....	29,492
1841.....	30,289
1842.....	30,502
1843.....	28,936

In proportion as people are better educated, and information more extensively diffused among them, will the lust for nostrums diminish. We infer this from the fact that in Scotland there is scarcely any sale for articles of the sort. This may, no doubt, be partly due to the circumstance that in the above country drugs have never acquired in vulgar estimation that exaggerated value which must inevitably be the case wherever medical men are remunerated for their wares and not for their attendance. We are firmly convinced, that were the profession established on one general scientific footing, to the exclusion of all trade in pharmacy, the proceeds from stamps and patents to the sale of secret remedies would eventually dwindle to a nullity. Ministers might in this way be saved the trouble of repealing so odious an impost.

It has been said, can any reason be given why you should prevent a man from bettering his fortune by making a useful discovery in medicine, when in every other department of science and art the State allows individuals to protect themselves by concealment, or affords them the exclusive use of their invention for a certain time, if they chose to make it public? To this our answer is, that nearly all the so-called discoveries in medicine which their authors have thought fit to shield by patent, have been mere impositions. Let a man who has found out anything new and important, communicate it fairly and openly, and he will have his reward.

The Marquess of Normandy expressed a hope last week that Govern-

ment was prepared to introduce some stringent regulations which would have the effect of putting a stop to the indiscriminate sale of drugs now permitted. We think Government could not do better than modify Lord J. Cavendish's preamble, by enacting that all persons who sold medicines, and who were not regularly bred to the profession of doctors, &c. should take out a license, after having been properly educated and duly examined by a Board under its own control.

MOVEMENT IN THE PROFESSION.

WE have received a printed document, of the 12th current, signed by eighty members of the Royal College of Surgeons practising in Hampshire, addressed to the Council, expressive of their great dissatisfaction, and of the deep sense of the injustice with which they have been treated under the new charter. These members protest against the injustice by which six hundred of the body have been arbitrarily selected to form a higher class, who have neither had a better classical education, a more extended professional one, nor have submitted to a stricter examination, than themselves; whilst they, their professional equals, are required to submit to a second examination in order to attain the rank bestowed without examination on the others.

A copy of a remonstrance to the same purport as the above has been forwarded us from Bath, and to which forty-one names are attached. It was signed, we are informed, within a few hours, by almost every member of the College practising in that city.

The National and Manchester Associations have each propounded their views as to what should be the main points of the charter they desire. On one head they are absolutely at variance. The Manchester Association proposes that the country members should vote by proxy, while the National Association would wholly exclude proxies. Now, says the *Times*, this would be most unjust to the country members; it would virtually deprive them of all direct influence in the government of the College, throwing it almost exclusively into the hands of

the London members; and it may be easily foreseen "that unless the National Association agrees to voting by proxy, they will soon be national only in name. They should at once declare their approval of voting by proxy; if they do not, they will speedily find themselves deserted by almost the whole of the country practitioners."

MEDICAL TESTIMONY.

WE were reminded of Chief Justice Dallas' memorable declaration at Severn and King's trial, that "these are not days of triumph, but days of humiliation for science," on perusing the report of a case tried in the Court of Queen's Bench on Saturday last. The nature of the action was as follows:—The defendant, a gentleman of the name of Lowe, aged 64, but vigorous and healthy, was about two years ago seized with a pain in his toe, which turned out to be spontaneous gangrene. He applied to Mr. Baker, a surgeon at Hampton, and the plaintiff in the cause, who administered stimulating medicines, with brandy, meat, and wine; and after four or five days removed the toe. The disorder continued, however, to spread over the foot; and Mr. Liston, who was called in, cut off that also, after having in vain tried to save it by the adoption of the "soothing system," the very reverse of Mr. Baker's, consisting in the abandonment of "stimuli," in the administration of sedatives, and in temperance and quiescence. Subsequently the plaintiff continued his attendance upon the defendant, and finally sent in his bill, which included 437 visits at 7s. 6d. each, with a charge of £13 for medicine,—in all £193 odd. The defendant, loth to part with both his foot and his money, refused payment, and the action was brought to recover the amount.

The counsel for the plaintiff, anticipating the defence, brought forward three surgeons of note, together with Mr. Liston himself, in order to prove the propriety of the treatment. Their joint evidence went to show that "spontaneous gangrene was not the result of any previous external injury to the part affected, but the symptom and the consequence of a debilitated constitution, and that such debility may co-exist with the appearances of health and vigour in the patient, and that it might therefore have been pro-

per in such a case, as the one in question, to have administered stimulating medicines, and to have allowed stimulating diet." In the face of all this comes the evidence of other three surgeons of repute, who give as their deliberate opinion, taking the representation to be correct, that the administration of brandy, meat, and wine, was totally incorrect, as it must have tended to increase the inflammation and extend the disease. Further, that to cut off the toe was the worst course which could have been pursued, as the necessity for amputating the foot appeared to have been the result of removing the toe; in short, that the treatment of the case was wholly improper.

Notwithstanding such conflicting testimony, the jury, after having retired for about half an hour, found a verdict for the plaintiff, £138 14s., in arriving at which sum they calculated the visits at 5s. a-piece.

THE NEW POLAR EXPEDITION.

THE ADMIRALTY'S TREATMENT OF THEIR MEDICAL OFFICERS.

SOME months ago, speaking of the treatment which medical men are so apt to receive from the various public departments of the state, we had occasion to mention the shabby way in which the medical officers of the late Antarctic Expedition had been met. Every officer engaged in that expedition, from the Commander downwards, received a step on his return, save and except the medical officers; they alone got nothing; naked they went out, naked they came home, naked they still remain! Yet did these officers voluntarily consent to expatriate themselves from their homes, and to encounter the dangers of unknown seas, for the long period of four years, and finally brought back their crews without the loss of a man from disease. More than this, the Antarctic Expedition was without any naturalist beyond a botanist; and as for the prospects that could be entertained of a botanist being of any use among the ice-bound islands or continents of the Antarctic ocean, he might as well have been left at home; but where the vegetable world fails, there does the animal kingdom teem with unusual life; and so it turned out. The medical officers of the Antarctic Expedition performed

the duties of general naturalists, and brought home many new and unknown, and interesting specimens, both of minerals and animals.

There is another Polar or Arctic expedition in process of being fitted out, the *Erebus* and *Terror* are getting ready in the river for the Polar Seas. Surgeons, we presume, will be required for these ships; but will any be found ready to volunteer their services in an expedition from which nothing is to be looked forward to but risk and privation in its course, heartless neglect when it is concluded? We have heard it stated that the surgeon who accompanied Captain Back was actually the *eleventh* who had been appointed—ten struck—would not go; the *eleventh* had it signified to him that he had better make a virtue of necessity, and accept. Our brethren have had the farther experience of the Antarctic Expedition to cool their zeal for Her Majesty's Naval Medical Service; and we trust that the Director-general of the Navy Medical Department will find not *ten* but *twenty* surgeons with courage enough to say nay to his proposals for a voyage in either the *Erebus* or *Terror*; the conclusion of which, in so far as the medical officers are concerned, will be an accumulation of scurvy treatment from superiors in office, and as the result of this, of contempt and neglect in the eyes of the world.

In the late army Brevets the poor medical men were alone neglected. Even the Commissariat were not overlooked: the provider of forage, of beef and mutton, soap and candles, and other mercantile matters for the army, had their benefit of these brevets; the men of science and education were alone left out of the question.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Tuesday, February 11th, 1845.

MR. STANLEY, President, in the Chair.

On Extravasations of Blood into the Cavity of the Arachnoid Membrane. By Mr. PRESCOTT HEWETT, Curator of St. George's Pathological Museum.

THE author, for the sake of perspicuity, arranges the extravasations in four divisions, according to their degrees of simplicity.

1. The extravasated blood may either be liquid or coagulated; if in the latter state, it may be in clots, or spread out in the shape of a thin membranous layer.

2. Sometimes the extravasation presents itself under the shape of a false membrane, possessing more or less of the original colour of the blood.

3. The blood may be fixed to the free surface of the arachnoid, and there maintained by a membrane which, to the naked eye, presents all the characters of the serous membrane itself.

4. The blood is frequently found enclosed in a complete cyst, of various degrees of thickness, which may be removed unbroken from the cavity of the serous membrane.

The author, having fully considered the various appearances put on by the extravasations mentioned in the first and second division, which were illustrated by cases and preparations, passes on to the more important subject of the third division, which, he thinks, derives an increased degree of interest from the fact, that these cases were for many years described as "extravasations of blood between the dura mater and the parietal arachnoid." After having quoted a case thus described by Dr. Hodgkin, he states that the result of the investigations carried on within the last few years by several foreign pathologists, and by himself, is so directly opposed to the opinion adopted by Dr. Hodgkin, that he cannot but think that that author has been led into an error, of which the case itself bears, he thinks, internal evidence. All recent investigations, illustrating this point, tend to prove, that the fine delicate membrane which covers these extravasations is not a portion of the arachnoid stripped off from the dura mater, but a newly formed membrane. This opinion is confirmed by the cases related in the fourth division, which were also, at one time, described as "extravasations of blood between the dura mater and its serous lining;" but the correctness of this opinion is made manifest by the stripping off of the cyst containing the blood from the parietal arachnoid to which it has become adapted. These points were illustrated with cases and dissections, of which two preparations were exhibited.

The author next proceeds to examine how this membrane is formed. He dissents from the generally received opinion, that it is the result of an exudation of lymph poured out from the arachnoid irritated by the presence of the blood; and thinks that the fibrine of the extravasated blood gives rise to the false membrane, independent of any inflammatory action in the neighbouring tissues. This he illustrates by various cases in which there were no appearances of inflammation either during life or after death.

1. Blood extravasated into various serous cavities, and covered over by a false membrane, without the least trace of inflammation in the neighbouring tissues.

2. Blood extravasated into tissues also becomes surrounded by a membrane, dependent upon the fibrine of the extravasated blood.

5. Even blood coagulated in the vessels at times is covered by a false membrane, also dependent upon the fibrine of the blood. Here are given two cases of large aneurism, cured by nature, in which the surface of the coagula was covered by a delicate membrane similar to the membrane of the artery; and one case in which a clot of blood was found, in a vein, covered by a delicate membrane, in which were several large vessels, as yet unconnected with the general circulating system.

With regard to the source of the hæmorrhage, the author thinks that, in those cases where no ruptured vessel has been detected, the blood must have been produced by an exudation from the rupture of some vessels so minute as to escape the ordinary means of investigation.

These extravasations the author has generally met with in cases where there has been a decided determination of blood to the head. He has met with them in cases of great and protracted anxiety of mind, in poisoning by opium, in drunkards, in delirium accompanying phthisis, in maniacal patients, and in aged people, in whom the arteries have been thickened by atheromatous deposit.

The author having pointed out the difficulty of the diagnosis in those cases which have been found to present the symptoms of diseases of a totally opposite character, concludes by directing the attention of the Society to the remarkable circumstance, already observed in several cases, of an intermission in the symptoms, either of coma or even of paralysis.

Mr. Stanley referred to a question propounded in the paper as to the proportion borne by cases of false membrane from effusion simply, to those resulting from inflammation.

Dr. Mayo made inquiry whether the false membrane itself did not present appearances by which its true origin could be determined; whether, in fact, it was the result of inflammation, or of mere effusion of blood?

Mr. Hewett replied, that the distinction between the appearance produced by an inflammatory effusion and those of an effusion of blood into the cavity of the arachnoid, might, he thought, be established; in the first case, the investing membranes of the brain were thickened and vascular, with effusion most frequently in the sub-arachnoid

cellular tissue, whereas, in the second case, the cerebral arachnoid generally retained its natural polish and thickness, and presented no increased degree of vascularity.

Mr. Stanley referred to some preparations of false membrane in the museum of St. Bartholomew's Hospital. In one of these cases the membrane was so adherent to the dura mater, that Mr. Abernethy at first sight considered it to be the arachnoid, but on separating it from the dura mater, that membrane was found perfectly smooth beneath it. In another case in which the patient had been maniacal for some time before death, the false membrane extended over the entire dura mater; and in another instance, there was a double false membrane, with effusion into the sac.

Dr. George Burrows made some inquiries of Mr. Hewett, in consequence of the abstract which had been read being insufficient to convey an adequate idea of the author's meaning. The cases before the Society had reference to the interesting question as to whether the blood of the extravasation retained its vital properties, and had the capacity of self-organisation? The delicate false membrane which surrounded these extravasations of blood into serous cavities, had the important properties, after becoming vascular, of acting as secreting and absorbing surfaces. It was, indeed, through the medium of these membranes that the extravasated blood became absorbed, and through their agency also, the irritating effects of these extravasations, which acted as foreign bodies, were mitigated and circumscribed. It did not appear from the paper, that it was clearly determined whether the false membranes in question were the result of a mysterious vital process in the effused blood itself, or whether they had their origin from the vessels of the contiguous serous membrane. He, Dr. Burrows, considered that the blood when effused had the capacity of exerting this vital power; but under these circumstances, as it acted on a foreign body, and, of course, produced more or less irritation in the contiguous parts, these vessels, under such influence, might throw out lymph or fibrin which might become organised at a subsequent period; although the vascular actions, or excited, might not amount to inflammation. Mr. Hewett conceived these membranes were not the result of vascular action in the arachnoid, because on examining its surfaces there were no signs of the existence of previous inflammation. Dr. Burrows inquired whether the author, in stripping off layers of lymph which had resulted from genuine inflammation, had not occasionally found the subjacent serous tissue scarcely at all altered in structure, and without any signs of increased vascularity? He, Dr. Burrows, had observed

this condition in the pleura, pericardium, and peritoneum, when they were thickened by effused lymph. These false membranes, highly vascular, were often found around extravasated blood in the substance of the brain. Dr. R. Bright, in the "Medical Reports," had given illustrations of some of these cysts which had formed round clots of blood in the substance of the brain. These sacs appeared to be more connected with the surrounding cerebral substance than with the extravasated blood.

Dr. Webster, like Dr. Burrows, complained of the abstract of Mr. Hewett's paper just read. It failed to fully elicit the views and opinions of the author. He wished to inquire of the author the effects which changes of structure of the arachnoid had on the mental faculties. In 72 cases examined by Mr. Lawrence at Bethlem, nearly a fourth exhibited thickening and opacity of that membrane of the brain. Mr. Stanley's case was an illustration of the fact also. Had Mr. Hewett observed maniacal symptoms in any of the cases he had detailed?

Dr. Cursham observed that one of the cases recorded in the paper was phthisis accompanied by mania.

Mr. Henry Lee stated that it appeared to him that the conclusions arrived at by Mr. Hewett were of the greatest importance, inasmuch as they involved the acknowledgment of an inherent power in the blood of generating vessels, and that quite independently of any increased action in the surrounding parts. But in estimating the truth of this proposition much important evidence is gained by considering the analogous processes which take place under similar circumstances in other parts of the body. Mr. Hunter states that when a small extravasation takes place in the cellular membrane, if the blood coagulates, the union of the ruptured vessels is produced by the coagulum becoming vascular; and he also states that when the coagulum is large the whole will not become vascular, but that surface only which is in contact with the surrounding parts. The analogy between this process and that described by Mr. Hewett appears sufficiently evident. Another illustration of the same subject is where blood has been retained for a considerable time in a vein by means of pressure. The exterior portion of the coagulum, as in an instance to which Mr. Lee referred, will shew a thin firm layer, distinct from the central and more uniform substance. This layer may be mistaken for lymph effused upon the lining membrane of the vein as the result of inflammation. The chief diagnostic mark between the two is, that whereas the lymph adheres to the whole surface from which it is secreted, the layer derived from the coagulum

of the blood has very partial adhesions, and may be separated from the coats of the vein with the greatest facility. A difficulty may present itself in considering in what way it is possible for vessels to form spontaneously in a coagulum; but in granting this power to exist, we allow nothing more than that which continually takes place in the development of the fœtus, where the blood is formed before the capillary, the capillary before the vein, and the vein before the heart. But from whatever source the vessels are derived, the mode of the formation of the false membranes, or the exterior vascular layers, would appear to be strictly analogous in all the cases referred to.

Mr. Solly, in all cases of patients dying from acute mania whom he had examined with Dr. Conolly at Hanwell, had always found effusion of blood upon the surface of the brain. In respect to the diagnosis of effusion of blood upon the brain, he had found one symptom invariably present, and this was, an acute pain in the head.

Dr. Dickson confirmed a statement of Mr. Hewett with respect to the alternation of coma and paralysis in one case which he had seen with that gentleman. In that case there was no effusion into the arachnoid, and no adhesion of the false membrane, so that it was difficult to conceive that it had been the result of inflammation. He recollected seeing, in 1827, in the Hôtel-Dieu, a case in which there was aneurism of both popliteal arteries. Dupuytren refused to operate, as the arterial system generally was diseased. The man died, and in the larger aneurism there were twenty or thirty layers of false membrane, and in the smaller, ten or twelve layers. The disease was of old standing in one of these, and here the layers were like serous membrane. In the more recent tumor the layers were thicker, resembling the buffy coat of the blood after it had been subjected to pressure.

Mr. Prescott Hewett had had frequent opportunities for detaching a false membrane from a serous surface, without finding any increased degree of vascularity in the serous membrane; but then these cases were, as Dr. Burrows had stated, of some standing, whereas the cases mentioned in Mr. H.'s paper were, for the most part, quite recent. Of this, the case read by the Secretary was a good example. The patient having survived a severe injury of the chest nine days only, the pleuræ was found filled with blood, completely enveloped in a false membrane two lines in thickness, and yet the serous tissue, in contact throughout its whole extent with the newly formed membrane, presented, with the exception of very slight roughness, the appearance of the opposite pleura, which was quite healthy. Mr. Hewett thought, that the pleura, had

the false membrane been the result of inflammatory effusion, would have, at so early a period as nine days, presented at any rate some signs of inflammation. He had come to the conclusion that the blood possessed the power of producing from its fibrine a false membrane, without the intervention of any inflammatory action, from many dissections which he had made, the details of which were given in his paper. He mentioned a case in which a loose coagulum enveloped in a transparent membrane with a smooth and polished surface, was found in the superficial femoral vein, the cavity of which it did not completely fill. The internal surface of the vein presented a perfectly natural appearance, with the exception of a few points where it was slightly adherent to the membrane enveloping the clot. He alluded also to some cases of aneurism cured by nature, in which he had found the slightly cupped surfaces of the coagula blocking up the aneurismal opening, which was about the size of a crown-piece in one case, covered over by a false membrane, so beautifully adapted to the original serous membrane of the artery, that it was impossible to point out the exact limits of each of these membranes. The false membranes enveloping the extravasation of blood, so often found in the ovaries, afforded, he also thought, a good example of this power of the blood. But one of the strongest proofs which he had seen of this power was in a man who survived injury of the head for nine days. In the cavity of the arachnoid was an extensive extravasation of blood divided into a visceral and parietal position; the visceral portion formed a thin, smooth, and flattened clot, which corresponded to the whole of the upper surface of the hemisphere. The parietal portion was disseminated in patches of various sizes and thickness, many of which were firmly bound down to the free surface of the serous membranes by thin delicate membranes of a fawn colour, with smooth and polished surfaces, and bevelled off at their margins so as to be adapted to the original serous membrane. Had the membranes covering these clots been the result of inflammatory effusion, they must have been produced by the visceral arachnoid, but that membrane could not have been produced by them, for it was, as already stated, covered by a layer of coagulated blood. Extravasation of blood in the cavity of the arachnoid had been frequently found in maniacal patients. Mr. Hewett had observed intense pain in the head in one case only, in which the pain put on the character of brow ague, lasted for two or three hours, and then disappeared, but recurred, for several days, twice in the twenty-four hours. The symptoms then became typhoid.

Dr. Burrows inquired, what was meant by an alternation of coma and paralysis, as referred to both by the author of the paper and by the last speaker.

Mr. Hewett explained, that coma came on at one time, and disappeared; that then paralysis came on, and also disappeared.

Dr. Mayo referred to a case which he had published in the *MEDICAL GAZETTE* as bearing upon the occurrence of brow ague as mentioned by Mr. Hewett. In this case the pain at first was periodic, and he thought he had been mistaken in referring it to pressure. It became worse under the use of the liquor arsenicalis. It subsequently became continuous, but was nearly removed by calomel and antimony.

On the Formation of the Buffy Coat of the Blood. By GEORGE GULLIVER, F.R.S. Surgeon in the Royal Regiment of Horse Guards. [Communicated by Robert Liston, F.R.S.]

After noticing the well-known fact that the red corpuscles will sink much faster in the entire blood, while the buffy coat is forming, than they will do in the serum alone, the author remarks, that two of the most eminent authorities on the physiology of the blood, Mr. Hewson and Dr. Davy, concluded that the rapid sinking of the corpuscles on which the buffy coat depends is due to an attenuation of the liquor sanguinis. On the contrary, Professor Hermann Nasse, and Mr. Jones, attribute the quick sinking of the corpuscles to their increased aggregation in inflammatory blood. (*British and Foreign Medical Review*, No. 28.)

Finding that the blood of the horse regularly affords a buffy surface, measuring as much perpendicularly as the lower red part of the blood-clot, the author made many experiments on the sinking of the red corpuscles in the liquor sanguinis, in the serum, and in these fluids variously altered in viscosity and specific gravity. The experiments are particularly detailed, in order that they may easily be repeated, and that no errors may arise from the different effects which Mr. Prater has shown may be produced by different quantities of the same substance.

The author is of opinion, that if we admit that the sinking of the red corpuscles affords an accurate test of the consistency of the liquor sanguinis, we must also admit the improbability that the liquor sanguinis becomes *thinner some minutes after the blood has been received in a vase*, at which time the falling of the red corpuscles is most rapid.

The author asks whether the well-known utility of saline medicines in inflammation may not be explained by their effects in preventing or destroying the aggregation of the red corpuscles, and in preventing or lessen-

ing the buffy or inflammatory condition of the blood.

The author arranges some of his conclusions as follows—

1. There is a remarkable acceleration, after a few minutes, in the rate with which the blood corpuscles sink in the liquor sanguinis.

2. The acceleration may be increased by increasing the aggregation of the corpuscles; and prevented or reversed by preventing or destroying the aggregation of the corpuscles.

3. The sinking of the corpuscles is slower in blood thinned by weak saline solutions than when mucilage is added with the salt.

4. The sinking of the corpuscles may be slower in serum artificially made thinner, and lighter than in serum artificially made thicker and heavier.

5. In the crur of horses' blood, the corpuscles are more aggregated, and with more appearance of agglutination between the corpuscles than in very buffy human blood.

6. There may be no buffy coat, or only a comparatively thin one, on the blood of the horse, when the blood has been made thinner and its coagulation retarded.

7. The corpuscles of the horse sink much quicker in his serum than the corpuscles of man do in his.

8. Increasing the proportion of corpuscles in the blood hastens coagulation, and prevents or diminishes the formation of the buffy coat more than increasing the serum only.

CLINICAL LECTURE

ON

DISEASES OF THE SPINE.

By SAMUEL SOLLY, F.R.S.

Senior Assistant-Surgeon to St. Thomas's Hospital.

GENTLEMEN,—We must on this occasion return to the subject of rheumatic caries of the spine. I concluded my last lecture with the relation of a case which illustrates, in the most striking manner, the gradual and serious progress of this disease, and the obscurity of its symptoms in the early stages of it. To-day I shall relate a case in which the symptoms were more clearly developed in the first instance, and in which the progress of the disease has been arrested by prompt and decided measures.

Dec. 1842.—E. F., aged 37, fair complexion, slightly inclined to strumous diathesis; six feet in height, well-formed broad chest; great muscular power in lifting heavy weights; very temperate, and active habits; able to endure fatigue; not particularly robust, but seldom ill. Has lately suffered from occasional feelings of rheumatism in his joints, so that, on first moving them in the morning, they have felt stiff, and as if the surfaces grated upon one another: when suffering from dyspepsia, all his rheumatic feelings were aggravated. At the beginning of 1843 he first began to feel pain in his back, especially when leaning against a chair, and all chairs felt equally uncomfortable; but to this he attached no importance, believing the pain to be under the angle of the scapula, until his spine was examined, when he recognized the pain he experienced from tapping it as the same he had felt so long. He had a sensation of tightness round the chest, as if girt in by a belt. During this time he was a good deal harassed by business, driving and walking

about for many hours together. He gradually began to find that he could not walk so far or so fast, or so upright, as he used; and this inability increased upon him. He experienced a sensation of weariness in his legs, which he could not attribute to ordinary fatigue; it annoyed him a good deal, as he was fond of walking, jumping, &c. By degrees he found that he could not turn in bed without pain, and this increased in severity. His heart's action became irregular and intermittent. But all these symptoms he was disposed to attribute to dyspepsia, and the effect of anxiety in his business: at this time his bowels and liver acted naturally, but his appetite was uncertain and capricious.

About the middle of December, 1843, all these symptoms increased so much, and he became so irritable and nervous, that he came up to town and consulted me regarding them. From his statement I felt very little doubt as to their spinal origin. On stripping him I found no irregularity of these bones; but on tapping the spine downwards, as soon as I came to the third dorsal he cried out; the fourth and the fifth were also tender. He said that it was not acute pain that he experienced from the examination, but a horrible sickening feeling, which lasted more or less for a quarter of an hour afterwards.

From my house he proceeded, by my advice, to Sir Benjamin Brodie, who, after a careful examination, confirmed my diagnosis that it was a case of rheumatic caries.

I now insisted upon his lying down, without interruption, for at least two months; and although this, at the time, appeared to him to be a sacrifice of all his professional prospects, nevertheless, feeling that he required rest, he complied with the directions, and ordered a double-inclined couch for the purpose. For two days he kept the recumbent posture on an ordinary bed, but he was wretched, and he said that no words could express the relief he experienced on

being removed to his couch. On the ordinary bed he could scarcely place himself in any position in which his back was free from uneasiness or pain.

On the 24th of December, he commenced a course of mercury, by taking one grain of calomel three times a day, and six leeches to the region of the 3d, 4th, and 5th dorsal. From these he experienced relief, but they made him feel so weak, that for some days he could not raise himself in bed without fainting. He continued the same dose of mercury for three weeks, when his mouth became gently affected, and we now reduced it to a grain every night. At the end of six weeks he was able to turn on his couch without pain, and at the end of eleven weeks he was so well that I allowed him to leave his couch, but he could not sit up without fainting. I therefore ordered for him a spinal support, made by Mr. Bigg, of Leicester Square. This has proved so useful to him, that he has never experienced any feeling of syncope since its application, and he has continued to wear it with the greatest comfort ever since. He now took the iodide of potassium in two grain doses, with sarsaparilla, and in a very short time was again able to resume his professional duties, and which he has continued to perform with perfect ease and comfort to himself, with every feeling of health; and up to this time he has had no return of his ailments.

I think you will agree with me in regarding the three cases I have just related as pregnant with matter for serious reflection. The first point that I think must strike you is the length of period for which this disease may exist, and its real nature remain undiscovered; also, the extent to which the cerebro-spinal system may be affected before there is any alteration in the form of the vertebral column, or any external mark indicating disease of the osseous tissue. No one who has listened to the graphic account which my friend has written of the rise and progress of his sufferings, that I gave in my last lecture, can, I think, doubt that they depended on irritation of the spinal cord. But whence the exciting—the proximate cause of this irritation? In the ordinary, or strumous caries of the vertebra, I have already expressed my opinion that the subsequent paralysis is occasioned by fibrinous effusion into the canal, and not by the pressure of the overlapping bones, and so in rheumatic caries I have no doubt absorption of the bone, which ultimately demonstrates itself by the angular curvature, is preceded by inflammation of its substance. And, therefore, so soon as the inflammation of the bone has extended to the membranes of the cord, so soon do we have evidence of spinal irritation. If this view of the case be correct, it has a most important bearing on

our early treatment of this disease. Without troubling you with a detail of other cases of a similar character, those we have before us afford strong evidence of the truth of this view of its pathology. A. B. was always relieved, in the early stage of his disorder, by local depletion, and the disorder was evidently for the time arrested in its progress, though not altogether annihilated, as, its nature not being understood, the whole plan of treatment was vacillating and empirical. In Cripps' case, as soon as his system was affected by mercury, so soon did his paralytic symptoms subside. And in the last case, the same result followed the use of the same antiphlogistic remedies.

In treating this disorder as inflammatory, let me beseech you to remember, what I have so often dwelt upon in regard to the treatment of all affections of the nervous centres, namely, the general depression of the vital powers which attends an inflammation of their structure. It will scarcely ever bear active treatment, and the bloodletting should be almost invariably merely local. Indeed, all antiphlogistic treatment must be employed with great caution. Now, if the first case, that of A. B., exhibits the evils which ensue from a man pursuing his occupation, and following his profession, in spite of all his suffering, so does the third case demonstrate the value of perfect rest, with efficient antiphlogistic treatment, in staying the progress of this formidable disease.

I need hardly insist on the importance of a correct diagnosis and prognosis in these cases; and if it is important for you to distinguish between lateral curvature and angular curvature, so is it even still more important that you should distinguish between ordinary or *strumous* caries of the spine, and the *rheumatic* caries of Sir B. Brodie, for I am convinced that the two diseases are essentially different, both as regards their origin, progress, and termination, and the treatment required for their cure; and again, between the latter, and disease of the chord independent of disease of the bone. Sir B. Brodie, in a lecture published in the *Lancet*, of the 30th of Dec. 1843, has remarked that rheumatic caries is always accompanied with pain; scrofulous caries, though frequently, not so invariably; and in paraplegia, from disease of the chord, independent of disease of the vertebrae, there is an entire absence of pain. The history of each case will also assist you—the presence or absence of a rheumatic or of a scrofulous diathesis—the moral history of your patient, independent of disease of the chord being generally the result of excess in venery, by persons leading sedentary lives, and engaged in continual mental exertion. But in these last cases—and I have seen several—there is

no pain on tapping the spine. But, on the other hand, there are cases of spinal disease in which the diagnosis is not so easy. The patient suffers severe pain on pressure over the spinous processes, with total loss of power of the legs, but without any irregularity of the vertebræ, or other evidence of the existence of disease of the bones. The most anomalous symptoms, however, generally occur in females; and when we find in our examination of these cases that there is no evidence of a rheumatic tendency previously, that they have never suffered from rheumatic pains, and that the tenderness on pressure is not confined definitively to any particular portion of the spine, severe pressure not inflicting more pain than slight; again, the pain shifting, sometimes in one portion of the spine, sometimes in another; and if, in addition to this, you find clear signs of an hysterical diathesis, you may generally refer such ailments to an hysterical origin. This term, however, is liable to mislead; hysterical complaints are often set down as altogether imaginary, but such is not the case, they are often most serious to the patient, and most harassing and difficult to the practitioner.

There are cases on record in which females have been confined to their couch for years with most of the signs of spinal disease, and who have suddenly recovered the use of their limbs, and lost all pain in their back, under the excitement of some strong mental impression; such as the fear of fire having broken out in their house, &c. Then, again, there are other cases in which severe pain and weakness in the vertebral column had been induced by over-exertion in young and delicate females of tall stature, and slight muscular power, at a time when they have been lowered by menorrhagia, or other debilitating causes. Not long ago, I was consulted by a lady, residing in a healthy situation in Surrey, who is now 30 years of age, and has been more or less on her back for 18 years, but in whom there is no irregularity of the vertebral column whatever, or other indications of disease of the bone. She cannot bear the slightest pressure over the lumbar vertebræ, but finds relief from pressure over the dorsal and sacral vertebræ.

She first began to suffer pain in her back seventeen years ago, which she attributed to over exertion when suffering from menorrhagia. Her pain was always aggravated by a long walk, by carrying anything heavy, or any over exertion which produced fatigue; and this increased so much, that if she sat up for any length of time together, she lost the use of her limbs, but always recovered it after lying flat for a short time. After a year or two this was followed by violent spasms and cramps in her arms, by which her limbs were firmly fixed, horrible night-

mare, and a feeling as if a thick cord were tied round the chest: this spasmodic feeling was relieved by castor oil.

She gradually more and more lost the use of her limbs; at last, she could not sit up for more than fifteen or twenty minutes without experiencing a most distressing difficulty of breathing. She told me that after striving for three years against it, she found that not only could she not breathe, but that she had severe pain and anguish between her shoulders. During this time she only found relief from the very hardest mattress. She informs me that, now, the only way she can keep her back at all free from pain is by lying on a thick pad laid inside her stays; though it is very uncomfortable with it, it is absolute anguish without it, for then she can scarcely speak or move. She cannot lie in any position for more than two hours at a time, and finds relief by lying on her chest and on her right side, but never on the left. She is a sensible woman, of naturally good constitution, healthy parents, and has never exhibited any signs of hysteria. She is thin and wasted, and her digestion much impaired; she cannot digest any meat, lives principally on fish and vegetables, and farinaceous food. She is cheerful and contented. I persuaded her to try and sit up in a spinal support, similar to the one which gave so much relief in E. F.'s case, but the distress which the change of posture occasioned was frightful. She seemed almost suffocated; she described it afterwards as absolute inability to breathe, but not palpitation of the heart: this she felt subsequently.

My impression, after carefully investigating all the circumstances connected with this lady's afflictions, is, that her sufferings do not arise from any positive disease of the vertebræ; and my chief reason for this opinion is, that there is no deformity, although the disease has now lasted seventeen years, and the entire absence of rheumatic symptoms: nevertheless, the exact pathological condition is by no means clear. But its very obscurity renders the case instructive, for if it should prove to be rheumatic caries, to which in many respects it bears considerable resemblance, it will throw some light on it. If, on the other hand, it is a case of spinal irritation without actual change of structure, it shows to what an extent functional derangement may occur without disease. With regard to treatment, her extreme debility put all antiphlogistic measures, even of the mildest character, quite out of the question. You all know how much I value the cod-liver oil as a remedial agent; I was therefore much pleased when, after suggesting this with various other tonics, she told me that it was the only one that ever agreed with her.

Her general health has decidedly improved since she has been taking it.

Pathology of rheumatic caries.—Ever since I became acquainted with the existence of the disease which Sir Benjamin Brodie has thus designated, I have naturally revolved carefully what is the condition of the bones; are they really in a state of ulceration, as in strumous caries, or are they in a totally different condition? As I have not yet had the opportunity of examining the bones in this disease after death, all that I have to say on the subject is necessarily conjectural; and I do not wish you to receive my opinions in any other light than as a theory.

I believe that this disease is local, *mollities ossium rubra et fragilis*. I know that this view will be objected to, on the ground that *mollities ossium* is a general, not a partial disease, and that it is always fatal. In the paper which the Medico-Chirurgical Society did me the honour to publish, on the pathology of *mollities ossium*, I related two cases which occurred in the practice of Mr. Hodgson, of Birmingham, in which this disease was confined to one bone, and I have little doubt, that when the characters of this disease are better understood, we shall find it more limited than is at present supposed. It has been long known to the accoucheur that the bones of the pelvis will be alone the subject of *mollities ossium*, and also that they will again recover their natural condition. Dr. Rigby, in his excellent work entitled "A System of Midwifery," page 186, says, "*Mollities ossium* seldom attacks women who have had no children; sometimes it begins shortly after delivery, and very frequently during pregnancy, during the progress of which it continues to increase. Hence it occasionally happens that a woman has given birth to several healthy children without any unusual difficulty in her labours, and where, after this, the pelvis has gradually become so deformed from *mollities ossium* as to render delivery impossible by the natural passages." "Where the disease," continues the same author, "has ceased some time before death, and bone earth has been again deposited—shewing that the disease is arrested." Again, at p. 188 in the same work, we find: "*Mollities ossium*, to a slight extent, we believe, is not very uncommon, although cases of extreme deformity from this cause are of rare occurrence."

Dr. Davis, late Professor of Obstetric Medicine at University College, states, in his work on obstetrics, "that *mollities ossium* is in many cases an exclusive affection of the bones of the pelvis and of the inferior portions of the spinal column. A lady in the neighbourhood of the author's

residence had been the subject of severe pain in the back and loins for some months antecedently to her last pregnancy. These pains, as is usual in such cases, were referred to and treated for a rheumatic affection of the muscles of her loins. During her gestation the disorder became greatly aggravated, and she became totally helpless and bed-ridden. She eventually died. Upon examination after death, the pelvis presented the characteristic deformities of malacosteon; whilst, also, several of the lumbar vertebræ, which were imbedded in grume and pus, from ulceration and destruction of the immediately contiguous soft parts, were in a state of caries. No other parts of the skeleton of this subject than the pelvis had suffered distortion, nor could any of her cylindrical bones be discovered to have been in any degree affected by the disease." It is to be regretted that in this short description the exact appearance which the disease exhibited had not been more accurately described, but as far as it goes it tends to support my hypothesis.

In the paper which I have referred to in the Medico-Chirurgical Transactions, I have stated my opinion that *mollities ossium* is essentially an inflammatory disease, and as such ought to be treated; and if this view be correct, you will see that in this respect also it resembles this rheumatic caries.

I am very glad to be able to quote the opinion of the intelligent friend whose case I have related in his own words, in support of this hypothesis. In one of his letters he expresses the opinion "that the condition of the bone is simply that of *mollities ossium*; that *mollities ossium* is, as you have conjectured, *ab origine* inflammatory."

There is another circumstance which appears to strengthen this argument. During the progress of true *mollities ossium*, there is a deficiency of secretion of phosphate of lime into the bones, while there is an excretion of it from out of the system by the kidneys, the urine being loaded with it. In A. B.'s case the urine became phosphatic just previous to the alteration in the bone, which exhibited itself in angular curvature; and since he has been at Brighton he has passed a calculus composed of phosphate of lime, and shortly after this the urine ceased to deposit blood or phosphate of lime. The excretion of blood I believe was occasioned by the irritation of the calculus; his spinal disease was arrested. In one of his letters written at this time he says,—"you will be delighted to hear that I am a good deal improved. The hæmaturia terminated in a small calculus of the triple phosphatic character, since which there has been no news of importance from the renal districts. It is so long since I heard from my back that I am almost in hope that I shall never hear

from it again." This was written prior to the medical attendance which fatigued him so much, and threw him back again. So that it would appear that after the inflammatory stage had ceased, the natural deposit of lime into the bone was arrested, and then, but not till then, did the deformity of the spine take place, and when the abnormal excretion of this earth by the kidneys ceased, and its normal secretion by the vessels of the bone recommenced, then did his sufferings cease, and his recovery begin. In another letter A. B. makes the following ingenious suggestion: "If you consider phosphorus is required both for the brain matter and bone matter, you can get at something like a reason why nervous exhaustion should cause a diminished supply of phosphate of lime in the bones, for as the brain is more worthy than the bone, the constitution would give phosphorus for medulla first before bone."

Acting upon this suggestion, I should not hesitate to give phosphoric acid internally in this stage of the disease. It will do no harm even if it does not act specifically, for it is a good tonic, and often agrees with the digestive organs better than the sulphuric acid. You may begin with ten minims of the dilute acid in water for a dose.

I think that it must be evident to all pathologists who have examined the condition of the vertebral column after death in caries of these bones, that there are two different diseases; in the one there is a deposition of scrofulous tubercle, and the softening which exists appears to depend on this deposition; in the other the bones are red, and charged with soft grumous matter. It is true, that this form of disease is sometimes accompanied with suppuration, and so far this would appear to militate against my theory that angular curvature without suppuration is dependent on a different disease; but my object is to bring before you all the pathological facts which bear upon this subject, even though I may not be able to explain their relation to one another at present.

I was very much struck with the account of the post-mortem appearances in the following case related by Sir B. Brodie, in his work on *Diseases of the Joints**. The appearance of the bones is exactly similar to that which I have observed in true mollities ossium.

"CASE LXVI.—Edward Griffiths, 45 years of age, was admitted into St. George's Hospital, on the 15th of April, 1818, on account of an abscess which presented itself in the left groin. He said that about four months before his admission he had been seized with pain in the loins, and that the tumour in the groin had appeared about six weeks after the commencement of the pain. He was directed to remain constantly in the

horizontal position, and in a short time the tumor formed by the abscess in the groin disappeared, and another shewed itself over the os innominatum. On the 15th of May, this abscess was opened, and about forty ounces of pus were discharged. After this he gradually sunk, and died, worn out by profuse suppuration, on the 19th of August following.

On dissection it was found that the cancellous structure, and all the dorsal and lumbar vertebræ, was of a dark red colour, and softer than natural, so that they might be cut with a common scalpel, or even crushed by the pressure of the thumb and finger. The opposite surfaces of the bodies of the second and third lumbar vertebræ, and of the cartilage between them at the posterior part, were extensively destroyed by ulceration.

Anteriorly the bones and the intervertebral cartilage were entire, and the latter was in a perfectly natural state, but the bones throughout were of a dark and almost black colour. On one side of the body of the twelve dorsal vertebræ there was a small ulcerated spot, forming an opening which extended itself into a small cavity into the centre of the bone. The bone was also of a black colour, but the intervertebral cartilages connected with the other vertebræ were in a perfectly natural state.

The abscess had originated in the carious surfaces of the second and third lumbar vertebræ, and had extended itself behind the left psoas muscle, as low as the upper and anterior part of the left thigh, where it made a turn backwards on the inside of the tendon of the psoas muscle, and thus made its way to the place where it was opened on the posterior part.

The ribs were throughout unusually vascular and brittle, so that they might be broken by the slightest force. There were vomice in the lungs, and tubercles in the liver."

But I must not detain you any longer on the consideration of these views of the pathology of rheumatic caries, by which name we will continue to designate the disease, until we can shew by post-mortem evidence that the term *mollities vertebralis* may be substituted for that of caries. Time and further facts alone can shew their truth or error; resting satisfied at present, that the diagnostic marks of the disease are strong and clear, that the plan of treatment which ought to be pursued is equally so, and that if the disease is not detected in its early stages, that your prognosis must be unfavourable.

I will now conclude with some further remarks on one point in the management of these cases, to which I have scarcely sufficiently adverted.

In the treatment of all affections of the spinal chord, whether dependent on disease of

the vertebrae or not, it is especially important to bear in mind the sympathy which exists between it and the brain. The mind must be kept at rest; the mental powers must not be exerted; the mental energy must be husbanded, or the spinal chord will suffer.

The brain itself is more irritable, and less capable of enduring fatigue. I have lately seen this painfully illustrated in the person of my friend, to whom I have often referred. He had been obliged to attend an old patient of his, who came to the same watering place as he had chosen for his own health.

The case was an anxious one, and the attendance was heavy. The consequence was that he felt, to use his own words—"the full amount of nervous force very sensibly diminished, which proved itself to me by occasional giddiness, sleeplessness, and loss of flesh."

In another letter he thus vividly enumerates the various ways in which the brain is sympathetically affected in these diseases.

"1. Despondency. 2. Torpor. 3. Strange sensations; *a*, a wave breaking forwards over the forehead; *b*, a sound or flash of light within the calvarium; *c*, spectral illusions—exceedingly vivid; *d*, tolling of bells in the ears; *e*, occipital pains. 4. Throbbing in the head—clappings. 5. Sleep disturbed; *a*, fearful dreams.

"To live in terror of those fearful dreams
That shakes us nightly—
—better be with the dead
Than in the torture of the mind to lie
In restless ecstasy." MACBETH.

b. Unrefreshing repose—morning weariness; *c*, broken by sensations of fire or falling.

Indeed, Shakspeare must have thought of *me* beforehand, when he penned this:—

"Oh! I have past such miserable nights,
So full of ugly sights, of ghastly dreams,
That, as I am a Christian faithful man,
I would not spend another such a night,
Tho' 'twere to buy a world of happy days:
So full of dismal terror was the time."

RICHARD III.

THE PERIODICAL MATURATION AND EXTRUSION OF OVA, INDEPENDENTLY OF COITUS, IN MAMMALIA AND MAN,

PROVED TO BE

THE

PRIMARY CONDITION TO THEIR PROPAGATION.

By TH. L. W. BISCHOFF,

Professor of Medicine, and Director of the Physiological Institute at Giessen, &c. &c.

Translated by

HENRY SMITH, Esq. F.R.C.S. &c.

[Continued from p. 506.]

THE following are my own observations in reference to this part of my

subject (*viz.* that the ova quit the ovary and enter the fallopian tube, when the act of coition is not effected at all):—

At four o'clock in the afternoon of the 7th December, 1843, I obtained a lamb, which had presented signs of being "at heat" about an hour previous, but which had not received the male. The animal was forthwith shut up alone. The following morning I admitted the male to it; he several times shewed a disposition to effect the act of coition, but was prevented. Since, according to Kuhlemann (*l. c.* p. 13, note), sheep remain "at heat" during twenty-four hours only; since Kuhlemann and Hausmann profess to have seen the Graafian vesicle open twelve hours after coitus, and Von Baer has observed the ovum of the sheep in the fallopian tube before the end of the first day afterwards; I thence concluded that the ovum would quit the ovary during the first twenty-four hours of the period of "the heat," and therefore had the animal killed between three and four o'clock in the afternoon.

The same afternoon I observed, to my great satisfaction, that a Graafian vesicle on the right ovary had burst. The spot did not project upon the surface of the ovary, but attracted observation by a delicate lively red circle of vessels around a small opening, an appearance already familiar enough to me in dogs and rabbits; but one which may be easily, and certainly has been very often, overlooked by such as are not experienced in similar investigations. The diameter of this small opening was about $\frac{2}{3}$ P. line, = $\frac{9}{100}$ millim. I then searched throughout the vagina and the entire uterus most closely for spermatozoa, in order to gain the additional negative certainty that no act of coition had taken place; naturally enough, however, I could not find a trace of them, since it had been rendered absolutely impossible.

On the following morning I searched for the ovum. I laid the fallopian tube upon a plate of glass, spread out the fimbriae of its infundibulum carefully, and examined them first with the simple microscope. I found nothing there, but remarked a thread of mucus (*schleimfaden*) gradually extending itself into the infundibulum, the particles of which, when viewed under the microscope, seemed to me to have a great resemblance to thrust-off cells of the membrana granulosa of the Graafian

vesicle. I then cut open the first third of the tube with a pair of fine scissors, separated the margins, and examined every little fold carefully with a magnifying glass, and the assistance of a fine needle. I was so fortunate as to find the ovum in that part of the tube, at a distance of 5 P. lines, = $11\frac{1}{2}$ millim., from its entrance. I consider this as an extremely lucky occurrence, notwithstanding my acquaintance with the object; for the investigation is really so difficult, that one cannot wonder when nine out of ten times the search proves fruitless.

The ovum, when removed from the tube, still presented, under the microscope, altogether the appearance of an ovarian ovum. The zona was still surrounded by the cells of the discus, and although they were not extended out into fibres, yet they had perceptibly commenced to coalesce together. The diameter of the ovum with the discus was 0,0079 P. in., = $\frac{1}{11}$ P. line, = $\frac{1}{11}$ millim. The yolk completely filled the interior of the zona, in the form of a finely granulated, slightly obscure mass. After I had separated the cells of the discus from the zona with a fine needle, I found the diameter of the ovum in the zona to be 0,0054 P. in., = $\frac{1}{15}$ P. line, = $\frac{1}{30}$ millim. The thickness of the zona itself was 0,0006 P. in., = $\frac{1}{150}$ P. line, = $\frac{1}{30}$ millim. I could not perceive a germinal vesicle shining through the yolk, though it is generally possible in the ovarian ovum of the sheep.

After the ovum had remained for a time in contact with an aqueous solution of albumen, with which some common salt was mixed, the following very remarkable changes were developed in it. Firstly, an endosmosis took place into the zona, whereby it was distended, and the ovum assumed a somewhat elliptical form, measuring after a time, in its larger diameter, 0,0071 P. in., = $\frac{1}{12}$ P. line, = $\frac{1}{10}$ millim., and in its smaller, 0,0060 P. in., = $\frac{1}{15}$ P. line, = $\frac{1}{30}$ millim. As a farther result of the same action, the yolk no longer filled the interior of the zona completely, but shrank away considerably from its inner surface. In the interspace between it and the zona, a small somewhat yellowish shining vesicle or granule, having a pretty strong refracting power, now became visible; it measured 0,0005 P. in., = $\frac{1}{180}$ P. line, = $\frac{1}{72}$ millim., and corresponded accu-

rately to what I have seen and described as existing in the neighbourhood of the yolk when it no longer fills out the zona, in the ova of rabbits and bitches found in the upper third of the fallopian tube. I have started the supposition that this corpusele might be the nucleus of the germinal vesicle, which had itself undergone liquefaction, and confess that I find this opinion rather strengthened by the investigation in question; for in this instance it was extremely probable that the germinal vesicle had disappeared but a very short time.

In addition to the above appearances, the yolk of this ovum, after its separation from the zona, presented the most deceptive appearance of an especial vitelline membrane that has ever presented itself to my notice. I remember, also, that several observers, Professor Bruns, for instance, state that they have seen this vitelline membrane particularly distinct, and especially in the ovum of the sheep. The yolk had a very sharp outline, which, under a certain adjustment of the microscope, appeared like a dark line, as though formed by a membrane. It seemed even as if an interspace existed between it and the granular vitelline mass. Notwithstanding, however, I remained convinced, even in this instance, that the yolk possesses no especial vitelline membrane besides the zona, but rather that it is a gelatinous or albuminous sphere, in which the vitelline granules are suspended and distributed. The fewer the latter in proportion to their connecting material, the less opaque and dark is the yolk; as is the case, for instance, in the ovum of the sheep. The surface and margin of a section of the sphere are for the most part formed of this connecting material, and give it therefore a very sharp outline, which appears to be produced by a fine transparent investment. That this is the correct explanation is proved, in the first place, by very careful observation with a good microscope; by the aid of which, and by very gently changing the focus, one can directly convince oneself of the relation of parts just now described. In the second place, by continued observation, I saw how the yolk evidently absorbed gradually the fluid which had penetrated into the zona. Here and there it swelled up to a certain extent;

the sharp outline was lost, whilst it remained at other points; so that this could not possibly have been produced by the bursting of a delicate investment. Thirdly, after I had burst the ovum by means of the compressorium, some of the separate fragments of the yolk even exhibited the same sharp margin, which could not therefore be produced by an investing membrane. Lastly, the before mentioned granule near to the yolk, proves that the latter could not possess an especial covering; for the granule must, at all events, have been previously within the yolk, although inclosed immediately upon its surface, but it was now free in the interspace between the yolk and the zona. Had the yolk possessed an investing membrane, this would have been impossible.

I attach great importance to this point, since this question respecting an especial vitelline membrane is decisive in reference to the further development of the ovum. As I must in the prosecution of this examination from time to time contradict it, I wished that others might also be strengthened or corrected in their views.

The above described observation, however, made upon a young animal, which had never been impregnated, and never been "at heat," proves altogether indubitably, and in the most complete manner, the maturation and extrusion of the ovum from the ovary, quite independently of coition.

On the 18th and 19th December, 1843, I first remarked that a large bitch which I had in my possession commenced to be "in heat." The vulva was much swollen, and the dogs followed her eagerly. On the 19th, I tried if she would receive the male. But, although she played about with him actively, she would not permit coition to take place. I then kept her closely shut up, and on the 21st admitted a dog to her again. She now seemed by her actions to be willing to receive the male: I did not, however, permit it, but separated the animals again. At ten o'clock in the morning of the 23d, I cut out the left ovary and fallopian tube, and closed the wound by suture. It proved on examination that the Graafian follicles had not yet opened; four of them, however, were much swollen, and had a diameter of 2 to $2\frac{1}{2}$ Par. lines = 4 to 5 millim. I removed them cautiously from out of

the stroma of the ovary, and placed them, as cleanly dissected as was possible upon a small plate of glass. As I opened the first, an ovulum, provided with its discus, escaped with the fluid; it had a diameter of 0.00078 P. Inch = $\frac{3}{17}$ millim. To my astonishment, this Graafian vesicle contained a second ovum, with a discus of 0.0081 P. In. = $\frac{1}{4}$ millim. in diameter. The three other vesicles also each contained an ovum of about the same size. The inner surface of the Graafian vesicle was already lined with delicate granulations, the elements of the mass forming the corpus luteum, which, as it appears to me, develop themselves from the cells of the membrana granulosa; I observed here, very distinctly, in several Graafian vesicles, the manner in which the ovula are stowed in them. The cells of the discus (namely) form a small cone, the roundish head of which receives the ovulum, with which it projects free into the cavity of the Graafian follicle, that being filled with fluid; with its basis it rests upon a point of the wall of the follicle, probably at the precise spot where the latter opens.

These ova, moreover, appeared evidently not yet fully matured for their exit. The Graafian vesicles, for instance, were not only not much thinned, but the cells of the discus were also not extended out into those fibres which denote the full maturity of the ovum. When they were removed with the aid of a needle from the zona, the ova in the latter measured 0.0060 — 0.0065 P. In. = $\frac{8}{17}$ — $\frac{1}{4}$ millim. The yolk completely filled the interior of the zona in all of them, and only in one little spot had the vitelline granules receded from it to such a degree as had the germinal vesicle. In these instances I could neither obtain an accurate sight of it so long as the ova were yet closed, nor when I had opened them with the compressorium. I think I may feel convinced from the foregoing details, that had the bitch received the male then, the spermatozoa would certainly have had time to reach the ovary before the Graafian vesicles had opened.

I did not kill the animal until five days afterwards, in order to be certain that the opening of the follicle had taken place. The very first sight of the ovary, indeed, immediately showed that it had opened. The tunica vaginalis of the ovary, formed by the peri-

toneum, contained a considerable quantity of limpid serum. Four corpora lutea were well developed in the ovary. In two of these, the mass of granulations forming them grew out a considerable distance from the previous opening in the follicle, in a manner which I have seldom seen in the dog. The opening had probably closed at an earlier period in the other two, before the mass of the corpus luteum had arrived at so considerable a growth, and they were therefore now imbedded in the stroma of the ovary.

After I had carefully dissected the fallopian tube, I extended it out upon a wax tablet, and opened it with a pair of fine scissors: I found the four extruded ova already far advanced in its cavity; they were close together at a distance of 3 P. in. = 8 centim. from the ostium abdominale. The tube itself was 5 P. in. = 13 centim. in length. Three of these ova had the usual normal round appearance; the fourth, on the contrary, had an anomalous form, such as I had often previously seen in the dog, being elliptical, or almost like the figure of a guitar. All still had their discs around the zona, yet it was clear that these cells no longer retained their full, normal appearance, but had already commenced to undergo liquefaction. The ova had somewhat increased in size, for they measured with the discus 0,0090—0,0097 P. in. in diameter. Such was not the case with the yolk, for that seemed rather to be somewhat condensed, and on that account it no longer completely filled out the zona in all the ova. It had its usual form, and no trace of a division was developed in it. In the interspace between the yolk and the zona in one ovum, that large vesicle or granule ($\frac{1}{10}$ P. in. = $\frac{1}{32}$ millim.) which, as it seems, is always observable in ova at the commencement of the tube, presented itself: I have on a former occasion pronounced it to be the nucleus of the germinal vesicle. I saw nothing of the sort in the other three ova. I no longer found any trace of the germinal vesicle itself in any of the ova.

I do not believe it to be possible to prove the entire process of the maturation and exit of the ova during "the heat," and without coition, more completely than it is done by this twofold observation instituted in one and the same animal.

On January 4, 1844, I obtained the

genital organs of a sow, which had manifested the strongest signs of "the heat" during 48 hours, but had not been admitted to any male. The Graafian vesicles, however, were still closed. A considerable number of these, indeed, were much developed in both ovaries, and were very conspicuous from the rest, in consequence of their greater vascularity; but none of them had burst, and I forthwith obtained the ovum from one which I had removed from the ovary and opened upon a glass. It was, as usual, surrounded by the cells of its discus, which, moreover, were still round, and not extended into fibres. It measured in the diameter of its zona 0,0060 P. in. The yolk, which consisted for the most part of pretty large fat globules, did not completely fill the interior of the zona. After I had removed the cells of the discus with a needle, and the ovum lay level upon the glass, its diameter had increased to 0,0068 P. in.: the yolk now filled the interior of the zona completely, and as its particles had receded somewhat from each other, a clear circular spot became apparent at one point of its circumference, and which was readily recognisable as denoting the presence of the germinal vesicle, although, being covered by the vitelline granules, its outline was not perceptible. In fact, on crushing the ovum by gentle pressure, the vesicle with its germinal spot came out free; the spot was unusually large, but did not admit of any insight into its structure even under a very high magnifying power.

Thus this animal was evidently killed too early, at a time when the phenomena of "the heat" had not yet advanced to the opening of the Graafian vesicles, and exit of the ova.

Some weeks previous, on December 4, 1843, I had examined the genital organs of another sow, which had been kept distinct from the male from its birth. The possessor of the animal assured me that on former occasions he had several times observed it to exhibit signs of "the heat," and that they had been present again at the time of its death, but he could not afford me the necessary information as to how long they had existed before death. On examining the ovaries, it appeared that fresh corpora lutea were present in both. There were eight on the right ovary. In size they were all equal to

large peas, and projected considerably forwards upon the surface of the ovary. They had a dark brownish-red colour. A small bright red coloured spot was observable upon the highest point of each of them, but a distinct opening was no longer perceptible. When, however, the tunica propria of the ovary, with its serous investment, was dissected from off the surface of one of these corpora lutea, it presented a small opening precisely corresponding to the above mentioned spot. The corpora lutea consisted of a peripheral stratum (about a Parisian line in thickness) of flesh-like granulations, just such as are always developed from the inner surface of a Graafian vesicle in its transition into a corpus luteum. This enclosed a considerable cavity filled with a dark red coagulum, which was intimately connected with the granulations. I could not discover an ovum in any one of them. On the left side were two corpora lutea presenting the same condition; near to these, two others, which were considerably larger, and had an almost transparent reddish glistening appearance. The peripheral stratum in these was much less developed than in the others. It enclosed a pellucid, reddish coagulum, and also a considerable quantity of what looked like an uncoagulated fluid, but which coagulated so soon as it was exposed to the air upon a plate of glass. This coagulum was also connected to the walls. These two last described might have been taken for Graafian vesicles which had not as yet burst, for the mass of the corpus luteum commences its development from the walls even previous to its opening—such is the case, at least, in the bitch. But, 1, the small red spot on their summits, the point of opening, 2, the extravasation of blood which had taken place into their interior, and 3, the absence of an ovulum (which, at least, I could not find) may be received as evidence that both these vesicles had also already burst; but that then (as I have also seen in bitches in which I found the ova in the fallopian tube) the opening had again closed, and a second secretion of liquor sanguinis had taken place afterwards into the evacuated vesicle, whereby it had once more become distended.

Unfortunately I did not succeed in finding the ova in the tubes, although

I searched for them carefully for several hours. But it is a task of so much difficulty, both from the considerable width and length of the tube, and the many folds which it has, that I do not consider this negative result as proving anything. Besides, it is probable, that the ova, being unfecundated, had already undergone liquefaction. The advanced development of most of the corpora lutea, as well as the fact of the uterus and vagina no longer presenting any striking degree of turgescence, seemed to indicate that "the heat" had already some time since passed over.

I saw completely developed corpora lutea in the ovaries of another sow, which had likewise never received the male, and which had been observed to be "at heat" fourteen days previously, but I felt that it would be to no purpose to search for the ova.

Soon after, however, I obtained the genital organs of a young sow which had never been with young, and which I knew for certain had been shut up alone for the previous thirteen days. The first traces of "the heat" appeared five days before, and after that they had commenced to pass off, the animal was killed (on the morning of the fifth day.) It was evident, at the first glance of the ovary, that the ova were already extruded, for seven recent corpora lutea were developed on one of them, and on the other, six. There was no longer any opening perceptible in them, nor did they any longer contain large cavities filled with blood or serous fluid, but the Graafian vesicles were already filled up by granulations of the usual character. The point of rupture, however, was still distinctly recognizable from its deep redness. I proceeded at once to make an accurate investigation of the fallopian tube, which was about 11 Paris inches in length, and very full of folds, particularly in the first half of its length. By removing the epithelium cautiously in small portions, and examining them with a simple microscope, I succeeded in finding ten ova in the lower portion of the tube, at about from two to four inches from the ostium uterinum, and at some distance from each other. When examined with the microscope, they bore a general resemblance to an ovarian ovum when deprived of its discus proligerus. They had a diameter of from 0,0064 to 0,0068 Paris

in. (about equal to $\frac{1}{15}$ Paris line, or $\frac{1}{8}$ millim.) There was no trace of albumen developed around the zona, but the latter formed the sole investment of the ovum, and had in most instances a thickness of 0,0005 Paris inch, $=\frac{1}{7}$ Paris line, $=\frac{1}{8}$ millim. The yolk did not completely fill the interior of the zona in most of the ova, and varied in its diameter from 0,0040 to 0,0054 Paris in. $=\frac{1}{20}$ to $\frac{1}{15}$ Paris line, or $\frac{1}{10}$ to $\frac{1}{30}$ millim. Its composition exhibited those larger fat vesicles which also distinguish the ovarian ovum of the sow; they were, however, in most of the ova, so unequally distributed through the vitelline mass, as to give it an irregularly spotted appearance. The outline of the yolk was in this instance again so sharp, particularly in a certain adjustment of the microscope, that the existence of an especial vitelline membrane might have been assumed (as has, indeed, been the case with Dr. Meyer in reference to the ovum of the sow); but the same circumstances which I have already mentioned above in reference to the ovum of the sheep, here again afforded complete proof that such was really not present. I could no longer discover anything of the germinal vesicle; here, again, however, there was in some of the ova a very pale granule between the yolk and zona, which, as I have before stated, might correspond to the nucleus of the germinal vesicle, the germinal spot.

These three observations, then, upon the sow, furnish, so far as regards that animal, the most complete proof of the law laid down by me.

[To be continued.]

OBSERVATIONS
ON THE
NATURE AND TREATMENT OF THE
MORE IMPORTANT DISEASES
OF THE NERVOUS SYSTEM:

With Illustrative Cases.

BY EDWARD BLACKMORE, M.D. Edinb.
Member Extraordinary of the Royal Medical
Society of Edinburgh, and Physician to
the Bath Penitentiary.

[Continued from page 675.]

The treatment of Hydrocephalus.—A review of many cases shows that the fatal event was owing to early neglect, after the symptoms of an oppressed brain

had shown themselves; if the first week has passed without proper remedies, the case is often hopeless.

That the treatment should be actively antiphlogistic in the early stage, is generally admitted; but the records of cases show that leeches are sometimes trusted to, when a general bleeding ought to have been employed. Every practitioner of much experience will have had reason to regret that he had not bled more largely in the early period of this disease. I have bled a child eighteen months old, from the back of the hand, where alone a vein could be found, to an ounce and a half, with the best effect; and have seen stupor and obstinate febrile symptoms instantly relieved by a single bleeding from the jugular vein, when the most active medicines had been given in vain. Bleeding from an artery in children seems to be injuriously infrequent.

Next in value to bleeding, is the cold affusion; or a long-continued stream of cold water on the head, or applying a cooling lotion with a large paint-brush, which is preferable to laying a wet sponge or cold cloths on the head, the refrigerating effect being certainly greater. A spirituous lotion is not always so safe as plain vinegar and water; for alcohol in the lotion has seemed to excite delirium.

Of sedatives, the colchicum is far preferable to digitalis: many cases show that mischief has been done by an administration of the latter drug such as would not generally be thought incautious; it has induced symptoms that falsely appeared to be the effects of serous effusion from the natural progress of the disease. The tincture of foxglove should never be given to young children, nor to older subjects of a weak habit, after chronic disease in other parts of the system. In cases, beyond the age of infancy, when there is much delirium with a small tense pulse, narcotics have been given; they are safe and often highly useful, after proper bleeding; but at the beginning of the disease, or during the height of the inflammation, they are decidedly hurtful; and even the favourite combination of opium with calomel is, I believe, often unadvisable: antimony with a purgative, and the steady affusion of cool water, are the best means of improving a hard quick

sharp pulse in children, when bleeding cannot be carried farther.

In the latter stages of the disease, when much mercury has been given, and the system is irritable, henbane or muriate of morphia is safe and beneficial; but when opium has been given, having appeared to be required by the intermittent headache, its effect has been a matter for regret.

The extensive pustulation of the scalp by antimonial ointment has appeared a powerful means of lessening the stupor: but its irritant action has induced delirium.

Mercury, employed so as to affect the system, without previous bleeding, has not been successful. The use of it by inunction, with small doses of calomel, has been more satisfactory than the enormous quantities of the latter which are sometimes given.

Costiveness being a predominant symptom, violent doses of drastic purgatives are sometimes given, with an unsatisfactory effect: the repetition of small doses of calomel and gamboge, or calomel dropped on castor oil, with a senna clyster, and the cold affusion on the spine, are better means of acting on the bowels.

The severity of the vomiting has led to an attempt to stop it by mineral acids, or by the hydrocyanic, not always with a desirable effect: the vomiting is a useful criterion of the state of the brain, and has seemed to relieve the inflammatory tension of the vascular system. If it is thought right to stop it, ether on the epigastrium I have found safe and efficacious.

The spasms in the latter stage of the disease are relieved by giving a little spirit of ammonia, and an opiate, applying at the same time on the spine a cloth wetted with tepid vinegar; or by dropping elder-flower water on the head, and administering a turpentine clyster.

For the depression of the circulation, that sometimes attends the outset of the disease, the cold affusion on the head, and a stimulant pediluvium, are the best cordials. A state of exhaustion also sometimes occurs in the progress of the malady, and death is threatened by a sinking of the vital powers: in one such instance, in a boy seven years of age, I gave half a pint of sherry in a few hours, with success! In such a state, of course, the cordial should be

given in very small doses, repeated at short intervals.

In a case where unequivocal symptoms of effusion seemed to forbid a hope of recovery, the child was restored by a combination of purgatives, mercurials, counter-irritants, and narcotics, in the course of two months.

CASE XXVI.—A child, $2\frac{1}{2}$ years old, in April 1821, appeared heavy in the head, and had restless nights; the symptoms were thought to be from dentition, from which it had generally suffered. About the middle of May it seemed worse, and on the 25th it became affected with urgent vomiting, costiveness, fever, and a tendency to stupor, with intolerance of light. On the 31st the vomiting and lethargy continued.

Purgative clysters, calomel and scammony.

The next day, being weak and low from purging, a little wine was given. This was followed by an increase of coma for the next four days, when fatal convulsions ensued.

Inspection.—The membranes of the brain adhering; fibrine on the arachnoid over the hemispheres; the brain very soft; serum in the ventricles, the floors of which were very thin, as if from absorption; scrofulous tumors in the optic thalami, and in the cortical matter of the cerebellum.

CASE XXVII.—A young infant, in September 1821, had shivering, screaming, and fever, succeeded in a few days by occasional convulsions; these symptoms continued for a fortnight, and were then accompanied by vomiting and costiveness alternating with diarrhoea, flushing of the face, swelling of the head, and spasms of the limbs. It was not apparently teething, and could suck well.

Leeches, calomel and magnesia.

On the 4th day of the more acute disease, spasms of the eye-balls, and stupor, were superadded; the pulse strong.

Leeches, a blister, calomel and purgatives.

The next day, more decided convulsions; the vital powers low.

Mercury, a warm bath, and a little wine.

The 6th day, heat of the head, and coma, which was relieved after the cold affusion.

Leeches, mercury and cold, repeated.

Thenslightconvulsionsandvomiting.

A blister on the head.

On the 10th day, apparent blindness, and the pulse irregular: wine-why given; and its use was followed by a return of vomiting and fever.

A blister and purgatives.

At the 14th day an extraordinary amendment; the natural and vital functions good, the sight restored, and the breast taken. In a few days more, however, about the middle of the fifth week from the first attack of illness, the vital powers sunk, and death ensued without convulsions.

Inspection.—The sutures firm: six ounces of serum in the ventricles; much thickening of the membrane; pus at the inferior part of the cerebellum, and an appearance of ulceration at its base.

CASE XXVIII.—A girl, aged 15, was affected at the end of March 1822, with symptoms of enteritis, which were relieved by the usual treatment in ten days. She then complained of headache for about a similar period, and used leeches with only temporary relief. On the 10th day of the head affection the symptoms were, slight pain in the belly, severe pain at the forehead, vomiting, which was always increased by the erect posture, costiveness, thirst, and dysury; the tongue white, the pulse low and irregular.

Bleeding to twelve ounces, the blood natural; the head shaven; calomel and scammony every four hours; and a purgative clyster.

The next day, little change, except that the pulse was more regular.

Ten leeches to the head, tepid sponging, an opiate clyster, and calomel.

The 12th day, the vomiting, which was checked by the clyster, returned; some hard stools passed; severe headache, followed by delirium; pulse 80, irregular.

Calomel and the clyster repeated, and leeches to the head.

The 13th day, headache and delirium severe; bleeding to eighteen ounces, followed by relief; then vomiting, and the pulse 126, and variable.

Purgatives, leeches, and a blister on the head, and calomel.

The 14th day, free purging, without relief of headache, or delirium; then a

little relief on eight leeches bleeding; the aspect typhoid; pulse 150, but after several more natural stools it fell to 120; the heat of the body by the thermometer 103°; the pupils fixed and dilated.

Mercurial purgatives, and cold to the head.

The next day, the pulse again 150; a squint and fits of screaming, with a tendency to coma, and involuntary stools. The 16th day, much delirium; pulse 160: 17th day, pulse 204, coma and death.

Inspection.—The dura mater vascular; serum betwixt the membranes at the base of the skull; the brain very firm; its arteries much enlarged; much serum in the ventricles. The small intestines vascular in the peritoneal coat; the mucous coat also vascular in spots, and abraded; the mesenteric glands enlarged and vascular.

CASE XXIX.—A boy, 6 years of age, at the beginning of December 1827, complained of pain in the head, and loss of appetite, and seemed to be wasting, but continued to go to school. At the end of ten days he was affected with vomiting, pain in the bowels and diarrhoea, and voided some worms. On the 14th, febrile symptoms, cough and pain in the side, in addition to the former symptoms.

Calomel and antimony, salines and digitals.

15th.—More headache and fever. the diarrhoea stopped, vomiting continued.

Leeches and purgatives.

In the next three days a remission of all the symptoms, except the vomiting, and he sat up; but in the evening of the 16th, acute pain in the head returned, with delirium, sleeplessness, vomiting and diarrhoea, but with little fever.

Leeches, and calomel with opium in small doses.

In the next evening, severe delirium and screaming alternating with stupor.

20th.—Still more stupor, and costiveness, the pulse slow and irregular, the skin cold. Three doses only of the calomel had been given, and the leeches which had been ordered three times had bled very little.

A blister on the head, the warm bath, sinapisms to the feet, scammony and calomel in repeated doses.

21st.—Less stupor and screaming.

In the evening, the vital powers low; costiveness, which had persisted for two days; pupils dilated.

A blister to the neck, a purgative clyster.

22d.—Copious stools from the clyster, calm sleep, the general circulation improved, but the pulse very irregular.

Mercurial antimonial ointment on the head, clysters, calomel and scammony.

23d.—The bowels purged, pulse more regular, more natural warmth, and a power of swallowing. In the evening, more stupor.

24th.—The vital powers sinking.

25th.—The pulse regular, stupor lessened; but the face flushed, and an occasional convulsive tremor; the pupils dilated. Death the next day, one week from the severe relapse, and from the first considerable disturbance of the pulse; a fortnight from his discontinuing to go to school.

Inspection.—The dura mater extremely vascular; the arachnoid opaque at the vertex and base of the brain; the pia mater extremely vascular, and coated with fibrine. Four ounces of serum in the ventricles; the substance of the brain condensed and vascular; the membranes of the upper part of the spinal chord also very vascular.

CASE XXX.—A puny boy, 4 years old, complained, about January 7th, 1830, of shivering and pain at the head, but not severe: pain also in the hypochondria, attended with costiveness, and followed in a week by delirium.

22d.—The case appeared to be chiefly pleuritic, for which the attendant ordered leeches to the side, and calomel, antimony, and scammony, with relief.

24th.—A slight cough remaining; a return of delirium with a comatose tendency, and an aspect of exhaustion.

The medicines repeated, and squills.

26th.—Delirium continuing, and slight convulsions; little fever; the bowels purged.

A blister and aperients.

27th.—The symptoms relieved. In the next two days, a return of convulsions.

Purgatives.

30th.—The vital powers low, the eyes vascular, the pupils not dilated, the head hot, bowels costive.

February 1st.—Spasm of the eye-

balls, and death in the fourth week of the illness.

Inspection.—The skull large and vascular; the dura mater and the membranes of the brain excessively vascular; fibrine on the arachnoid at the pons varolii; the brain large and condensed; the four ventricles formed one large cavity, filled with six ounces of serum. The arteries at the base of the brain enlarged and flaccid; serum in the vertebral canal. More intense appearances of membranous inflammation could not be exhibited.

CASE XXXI.—A fine girl, 5 years of age, about the 15th of May, 1830, was affected with pain at the head, feverishness, vomiting and costiveness: which continued more or less for a fortnight, without recourse to remedies—despair having paralysed the attendants, another of the family having died with similar symptoms.

15th.—Spasms of the limbs, stupor and moaning; the vomiting had subsided; the head hot, pulse regular; little fever.

The head shaven, leeches and cold to the head, a stimulant foot-bath, calomel with scammony in repeated doses; clysters; salines with colchicum and antimony.

On the next day, more sense, so as to complain of pain in the bowels; some squint, the eyes not suffused, but the pupils dilated; no fever; the bowels purged of fetid stools.

The medicines repeated, and mercurial antimonial ointment on the head.

21st.—The brain still oppressed; the pupils more dilated; the pulse regular, and not quick.

22d.—Vision gone, coma increasing.

23d.—In the same state.

24th.—The pulse quick, respiration regular; the power of hearing and of deglutition remaining, the limbs affected with spasms.

Clysters and tepid sponging.

25th.—Restlessness soothed; coma increasing.

26th.—Tranquil death.

Inspection.—The sinuses of the dura mater very much loaded with blood; the arachnoid very opaque and thickened; the pia mater very vascular and florid; five ounces of serum in the ventricles; their walls vascular and much softened, as was the optic thalami

and corpora striata; the brain's substance generally very vascular. The medulla oblongata much softened, and, as well as the optic nerves, coated thickly with fibrine. The arterious circle of Willis very large. Probably this case is not surpassed, in the peculiarity of its symptoms, and in the character of the morbid appearances.

CASE XXXII.—A fine boy, of a very precocious mind, was seized in his 5th year, while travelling, with acute pain in the head and vomiting, followed by constipation: a blister and purgatives were employed, and local bleeding omitted, the attention of his medical adviser being chiefly directed to the bowels, on the supposition that the head symptoms might proceed from worms. The usual symptoms of effusion in the brain followed, with convulsions and paraplegia; the sutures of the skull, which had been firmly united, gave way, and became widely separated: after this the stupor and convulsions abated, and his superior mental faculties remained, but when I saw him he was blind and palsied. Life was prolonged in this state for eighteen months. The cold affusion was the only thing that seemed to alleviate the symptoms.

Successful Cases.

CASE XXXIII.—A child, 3 years of age, on February 14th, 1830, had been lethargic, and costive for a week; then was affected with "fits," and tossing of the head, and about March 14th showed a tendency to stupor, but could at times notice objects; its arms were in perpetual motion, yet not altogether spasmodic; the pupils dilated; much emaciation; no fever.

Mercurial-antimonial ointment, calomel, magnesia, and henbane.

17th.—Quieter from the medicine.

20th.—Spasms subsided; more sense, but vital functions low; salivated by the mercury.

23d.—Exhaustion and costiveness.

Aperients.

24th.—Fits of screaming for two hours together, but no spasms; pupils dilated; eyes staring; sleeplessness, the head seemingly enlarged.

Calomel, Pulv. Ipecac. cum. Opio; Aperients.

31st.—The head much enlarged; eyeballs rolling much when asleep.

April 3d.—Sleepless and costive.

Calomel, castor-oil, and acetate of morphia.

Progressive amendment to the 16th, when it was convalescent; and in May it was continuing well.

In the last month of treatment, the child used of calomel a scruple, ung. hydrarg. fort. a drachm, croton-oil 12 drops, scammony a drachm, rhubarb a drachm and a half, magnesia a drachm, Epsom salts an ounce and a half, Dover's powder a scruple, acetate of morphia a grain, tincture of henbane two drachms.

CASE XXXIV.—A very fine boy, aged 7, at the end of April 1830, was affected with cough, and symptoms of encephalitis, for which leeches, with calomel and antimony, were used; but the symptoms persisting in the next three days, he was bled, on May 2d, to five ounces, which induced syncope; the blood was very sily.

Head shaved, leeches repeated, antimonial ointment, purgatives, salines, with colchicum.

The next day, some antimony excited severe vomiting.

4th.—The head relieved; cough remaining; pulse low.

A blister on the breast; salines.

6th.—Restlessness and much pain in the forehead; pulse low; scalp sore from the ointment. In the two following days, a similar state.

On the 9th, the vital powers extremely low, but he was sensible.

Stimulant fomentations. Mild food.

10th.—Cold and pulseless at the wrist; the action of the carotids also feeble; foetid stools passed.

Hot alcoholic fomentations; quinine and sherry wine.

By these means, continued to the 13th, the collapse went off, but pains in the head, cough, and feverishness, returned.

Stimulants stopped; squills and acetate of ammonia given.

The next day still better, but stools foetid.

Calomel with magnesia.

16th.—Cough easier; slight headache.

Medicines repeated, and meat-broth.

Convalescence progressive from the 14th to 25th.

During the state of collapse, in five

days, four ounces of alcohol were used as an embrocation, and twelve ounces of sherry, with half a drachm of sulphate of quina taken.

[To be continued.]

TEMPORARY PROTRUSION OF THE EYEBALL,

WITH LOSS OF VISION,
FROM RHEUMATIC INFLAMMATION FOLLOWING SCARLATINA.

BY ISAAC G. PORTER, M.D.

New London.

[THE following interesting case we extract from the American Journal of the Medical Sciences.—ED. GAZ.]

Though single observations in pathology are, ordinarily, read with little interest, yet they possess no small value when they throw light upon controverted physiological principles, or newly-discovered points in anatomy.

In the Dublin Journal for July 1841, is a highly interesting article, by J. M. Ferrall, Esq., exhibiting his views respecting the anatomy of certain structures in the orbit of the eye, and the pathology thence deduced. The benefit of these new views was not enjoyed by the writer while the following case was in progress, as they were not published in this country until nearly a year after its occurrence; but in no way, except by their adoption, can its peculiarities be explained. Granting the anatomy to be as maintained by him and others, and the difficulty is easily solved on common pathological principles.

Early in October 1841, a daughter of P. S—, six years of age, was attacked with scarlatina, then sporadically prevalent. The efflorescence was but slight, and the soreness and redness of the fauces transient, and of so little account, that medical advice was not then sought. No unusual exposure, or error in diet, could certainly be regarded as the occasion of what followed, though from the slight illness of the child, both may have occurred without the knowledge of her parents. Ten days, however, from the appearance of the rash, there were slight febrile indications, followed by symptoms of jaundice, the skin and albumina being discoloured, urine red and

sparing, fæces ash-coloured. This continued about a week, and, doubtless, arose from gastro-duodenal inflammation; and as it subsided marks of irritation in other portions of the intestinal canal were evidenced by fever, picking the nose, grinding the teeth, discoloured and offensive dejections, with other indications of infantile remittent fever. Profuse diarrhœa followed, and, as this yielded, severe rheumatic pains attacked the extremities. These made their appearance about two weeks after the rash, and were thenceforth intermingled with other symptoms, affecting sometimes the wrists and arms, and then migrating to the ankles—the part affected being so tender and painful as to forbid all pressure or motion. Moderate swelling was the only external sign of inflammation. The treatment, thus far, consisted in meeting symptoms as they arose. The jaundice yielded to counter-irritants and fomentations over the stomach and liver, with calomel, pulv. ipecac. comp., and laxative enemata.

The diarrhœa, as in other cases following scarlatina, was speedily checked by one or two mild cathartic doses of pulv. rhei, two parts, and hydrarg. chlor. mit. one part. The rheumatic pains were alleviated by anodyne fomentations and sinapisms, and pulv. ipecac. comp.

One month from the appearance of the rash, these pains, which had continued for a fortnight, began to diminish, when the right eye became swollen and painful. At first it was supposed to be confined to the lid, but it was soon evident that other structures were affected. The eye soon protruded one-half or three-fourths of an inch, giving a hideous aspect to the countenance, and was very hard and firm to the touch*. The lids became of a dark-red or purple colour, and so great was the projection of the eye that they were forcibly separated from each other one-fourth of an inch; the eyelashes, from the same cause, being removed far asunder. The conjunctiva assumed a peculiar aspect, lying in folds, surrounding or overhanging the cornea, as in chemosis, though "amber-coloured," being filled with serum instead of blood. The iris was scarcely

* Though not a case of hydrophthalmia, yet, from its appearance, it might justly receive one of its synonyms "buphthalmus," or ox-eye.

visible, and the cornea, so far as seen, was dull and hazy, though, owing to the encroachment of the conjunctiva, no satisfactory view of it could be obtained. The sight of the eye was probably nearly lost, yet from the age and debility of the child it was impossible to settle the point. The amount of pain did not seem very great, perhaps from her being constantly under the influence of anodynes. A sense of distension, or, perhaps, of itching, seemed almost constant in the swollen lid, and very slight friction with a brush seemed grateful, though pressure gave extreme pain. Reserving the treatment instituted for a subsequent place, we next advert to another phase of the disease. As the eye was reduced to its ordinary size, the hands and wrists became again painful, stiff, and swollen. Soon they were entirely relieved, when evident symptoms of pericarditis appeared. The countenance became indicative of extreme distress, and there were severe darting pains in the region of the heart, with palpitation, difficult, catching respiration, with inability to lie on the left side. At times there were paroxysms of faintness and distress, resulting in profuse cold perspirations. Occasionally there was febrile action, but the pulse was so weak as to forbid bleeding. A blister was applied to the region of the heart, and, under the administration of calomel, opium, and colchicum, the disease soon left her, since which time, after recovering her strength, she has enjoyed her usual health.

Was this true rheumatism, or only "an analogous affection," which follows scarlatina? Watson (*Principles and Practice of Physic*, p. 882), whose opinion is entitled to great respect, is inclined to believe that it is not genuine rheumatism; for he says, "I have noticed the painful joints were eased and benefited by friction, a circumstance which may help to distinguish this affection from true rheumatism. Another distinctive circumstance is, that although all these patients were children, the heart in no case became implicated with the tumid joints." The validity of this latter argument, the present case, with its strong cardiac symptoms, must destroy. That pericarditis may not occur after scarlatina unconnected with rheumatism, we will not affirm, or even that there might not

be a like occurrence while the joints were, or had recently been, swollen with that disease; yet in such connection, as a general principle, the old law maxim, "*noscitur a sociis*," will be of safe application. It may be of little importance whether this affection be or be not regarded as genuine rheumatism, yet, could the true pathology be ascertained, it might greatly influence our practice. As is true in that disease, so these pains are migratory, while their situation in the fibrous tissue, the aspect of the part, and the constitutional symptoms, are all likewise similar. The effect of remedies is also the same in both—colchicum, mercury, and opiates, proving in each equally serviceable. Is it not possible that, from the peculiar irritability of the system after scarlatina, the ordinary causes of rheumatism, acting in a slight degree, may be adequate to the production of the effects in question? and that, were the methods of cure, in severe cases, more decisive (in mild cases only the mildest means should be used), consisting of such articles as were used above, rather than in external applications, so apt in rheumatism to render it metastatic, yet, which are chiefly recommended by those who have alluded to the affections, as following scarlatina, it would be less likely to prove wandering, and thus dangerous?

That the affection may safely and properly be regarded as true rheumatism, we would also argue from that most interesting feature of the foregoing case, the protrusion of the eye; there having been, from our first attendance, a scanty secretion of thick and bloody urine, though symptoms of anasarca were never very prominent, yet when the swelling of the eye commenced it was referred to an œdematous state of the lids; but as it increased the impression became predominant that it was hydrophthalmia, and was so regarded by a consulting physician of large experience in diseases of the eye. The urine, however, exhibited no coagulability by heat, and the symptoms, including the serous chemosis, which prevented an examination of the internal structures, did not justify the diagnosis; and neither has the result (this disease) proved much more amenable to medicine than hydrophthalmia. On the supposition of its dropsical

origin, while anodyne and mucilaginous fomentations and poultices were applied to the part affected, nitre and digitalis were administered, without advantage to the eye, or in increasing the quantity of urine; and it was not until after calomel had been continued for some days that any benefit was perceived. The protrusion, however, continued nearly three weeks.

But the internal structure of the eye had received irremediable injury, and the sight was lost. The organ is now (November 1844) smaller than its fellow, its atrophied condition being manifest not only by inspection, but by laying the fingers alternately on each globe covered by its lid. There is also a duskiness of the conjunctiva, which has been persistent, except as it gives place to evident vascularity from the effects of exposure to cold.

We now return to the views of Mr. Ferrall, alluded to in the early part of this article. That gentleman, encountering a case of rheumatism, accompanied or followed by a painful affection of one eye, with evident projection of the globe three-fourths of an inch beyond its fellow, and being unable to account for the protrusion, instituted a thorough anatomical survey of the eye and its investments. A distinct sheath was found, surrounding the globe, of fibrous consistence, of a yellowish-white colour, and which protected the globe from the action of the muscles, &c. This fascia* he calls "*tunica vaginalis oculi*," and as it was this which was affected in the case which originated the investigation, and in two or three other cases where a similar protrusion existed, he named the disease "*rheumatic inflammation of the tunica vaginalis oculi*." I cannot better present my own views respecting the case which occurred in my practice, and which differs from Mr. Ferrall's only as it was a sequel of scarlatina, than by transcribing his words:—

"Protrusion of the eyeball, which, when attempted to be explained by uncomplicated periostitis, requires some stretch of the imagination, appears a very simple and inevitable result of inflammation of the *tunica vaginalis*

oculi. There are here no soft parts to receive and divide the pressure, or protect the globe. The tunic is supported by other fibrous layers on its outside, as well as by the muscles, of which they constitute the sheaths. Inflammation of this capsule must, then, be immediately followed by pressure, and when we recollect its conical form, and that, as happens in cases of inflammation of other fibrous tissues, effusion at once takes place into the cellular membrane connecting it to the ball of the eye, we perceive there is nothing to prevent the dislocation of the latter.

"This effusion into the cellular tissue will make itself evident in another way. The conjunctiva, at the place where it forms the fold, in being reflected from the eyelid to the eye, closes up the *tunica vaginalis* in front. At this point it will not only receive the pressure of the effused serum, but will become separated from its connection with the sclerotic coat by the extension of the infiltration; hence the amber-coloured chemosis without vascularity of the conjunctiva. Chemosis, originating in conjunctivitis, always presents, in addition to serous infiltration beneath, one or other of the forms of hyperæmia. The chemosis of which we treat is, in uncomplicated cases, the consequence of effusion from a deeper source."

SOME OBSERVATIONS
ON THE
MEDICAL TOPOGRAPHY, CLIMATE,
AND DISEASES, OF THE BIGHTS
OF BENIN AND BIAFRA,
WEST COAST OF AFRICA.

By W. F. DANIELL,
Member of the Royal College of Surgeons of
England, &c.

[Continued from p. 645.]

YOUNGTOWN, or Newtown, is another native village built on the verge of a swamp, at the entrance of the creek leading to Warrée, and directly opposite the town of Reggio. Towards the close of the last century it was the usual custom for slavers and trading vessels to anchor abreast of this village, and the traffic which originated from these sources tended to elevate it into a place of some repute; accordingly, we find, in several old works, minute directions given for the attainment of

* This fascia was previously described by Tenon, in a paper read before the French Institute in 1804. See "*Mémoires et Observations sur l'Anatomie, la Pathologie, et la Chirurgie, et principalement sur l'Organ de l'Œil.*" Paris, 1816.

its anchorage. In proportion, however, as the slave trade declined, this part of the river became less and less frequented, and was finally deserted on account of its insalubrity, the palm oil vessels preferring to remain near the mouth of the river, where the danger from noxious exhalations and other morbid influences was considerably diminished by the cool and invigorating sea breezes, and the more open expanse of the stream. The population of Youngtown varies from 600 to 1000, and, from the unhealthy situation, is exposed to much sickness. Lepra, psoriasis, scabies, frambesia, and other morbid affections of the skin, are common not only in these but in the other districts of the delta of the Quorra. With the exception of syphilitic diseases, these may in general be estimated as the most numerous. Variola occasionally occurs after long periods, when it assumes an epidemic character, invariably sweeping off two-thirds of the inhabitants of those villages exposed to its pestilential visitations. Several years since variola of a peculiar malignant type broke out in Soudan, and passed from thence into the neighbouring kingdoms of Haussa and Benin, and so fearful were the ravages committed in its progress, that the majority of the Warrée towns narrowly escaped depopulation. Among the native tribes that inhabit the maritime regions of equinoctial Africa, there is, perhaps, no class of diseases that creates more terror or dread than the prevalence of these variolous epidemics. As but comparatively few negroes escape with life, when once attacked by epidemic small-pox, this circumstance may satisfactorily explain why so few are pitted with its characteristic marks, and also account for the custom that prevails, in some countries, of swearing by this malady; an oath which, from its dire import, is held inviolate. The other Exanthemata but rarely if ever appear.

Warrée, Owarrée, or Jackrée, is the metropolitan town of this river, and the seat of government. It stands on the northern side of the island of Warrée, an elevated tract of land separated from the circumjacent marshes by a bifurcation of the creek eighty or ninety miles to the eastward of Youngtown; both branches again uniting into one stream, that enters the Quorra a short distance below Eboe, as above

mentioned. This isle, from four to five miles in length, furnishes many beautiful and picturesque specimens of African scenery, and is richly endowed with all the wild exuberance of tropical vegetation. Its soil is a rich argillaceous loam with a substratum of red clay, of a moderate altitude above the surrounding mangrove forests, and alternately embellished by native farms and broken woodlands, that remind the stranger of a more northern country. The site of the town is one of the most eligible that could have been selected, being judiciously located on a gentle slope that commands both ingress and egress to each of the two streams. The number of its inhabitants amounts to six thousand. The *Bombax ceiba* (silk cotton tree), *Adansoniadigitata** (baobab tree), *Omphalocarpum procerum* (gourd tree), *Nymphaea lotus*† (white lotus), *Indigoferu enneaphylla* (trailing indigo), *Napoleana imperialis*, &c. flourish more or less in the cultivated districts of the island, with the ordinary accompaniment of cocoa nut, banana and plantain groves, or class of trees which on the coasts of Western Africa usually indicate the propinquity of native villages and plantations.

In Benin and Warrée circumcision is performed on all the males at a very early age, and the surface of the body, shortly after the operation, anointed by a white carbonaceous substance mixed with palm-oil, which, from its reputed prophylactic virtues, has been thought to obviate any injurious consequences that might otherwise ensue.

Excision of the clitoris, a rite universally practised by the females of other nations more to the southward, does not appear to be implicitly fol-

* This beautiful tree, which grows to an enormous magnitude in Bornou and other countries of Central Africa, is sometimes found in the elevated sandstone regions near the coast. Several portions of it are medicinally employed by the negroes in various maladies. In the interior it is known under the names of *kuka* or *kouka*, and Clapperton remarks, that "both leaves and fruit are considered to a certain extent medicinal. The leaves, mixed with trona and gussub, are given to horses and camels, both for the purpose of fattening these animals, and as a cooling aperient. They are administered to the former in balls, and to the latter as a drench. The white mealy part of the fruit is very pleasant to the taste, and forms with water an agreeable acidulous beverage, which the natives, whose libidinous propensities incline them to such remarks, allege to possess the virtue of relieving impotency."—*Journey from Kouka to Marmur*, p. 11.

† The sacred lotus of the Egyptians.

lowed by the women in this river, unless it is by those who have been formerly resident in some of the Eboe towns on the Quorra. A process, however, of quite a dissimilar character, is adopted by many females of the Jaboo country, and the result is, I believe, considered by them as ornamental; the clitoris is artificially elongated by means of small weights appended to it, and gradually increased in size until it has been lengthened several inches. Instances have come under my notice in which ulceration had gone on to such an extent as to require its immediate removal. In girls the catamenia generally appear about the eleventh or twelfth year, but their commencement and subsequent continuance often depend on the mode of life, habits, and constitutional peculiarities of the different grades of females, and likewise on those climateric agencies which so materially modify this uterine secretion. Pleuritis, pneumonia, phthisis pulmonalis, with other morbid conditions of the parenchyma of the lungs, are of greater frequency during the cold rainy months, and are accompanied by more vascular excitement than in the similar affections that occur in the dry months. Dysentery, diarrhoea, colic, and numerous disorders of the chylipoietic viscera, may be also more prominently noticed in the rainy months. Phthisis and dysentery are the most fatal complaints in low marshy localities, and carry off numbers of the aged and debilitated slaves. Of the species of intestinal worms, teniae and ascarides are the most common, particularly the former, and the populations of several inland countries not unfrequently suffer severely from their continual existence. Women, and the inferior class of slaves, who live exclusively on vegetable food without condiments, are those chiefly affected. More recently, the introduction and plentiful supply of European salt has somewhat diminished their occurrence. Hepatitis, induration, and other organic lesions of the liver, are rapidly increasing among the male inhabitants, from their immoderate use of ardent spirits of a very inferior quality, now abundantly brought by European traders for barter. Dyspeptic, and a wide range of nervous disorders, equally emanate from the same stimulant causes. Cerebral diseases of a very serious nature seldom

come under observation; but cephalalgia from febrile disturbance, constipation, and exposure to the sun, is extremely prevalent in both sexes, and at all ages. The custom of repeatedly shaving the head of every infant for several months, nay, even years, after birth, is one universally in vogue throughout these countries of the Bights, and is evidently regarded in the light of a prophylactic measure of no mean value. I may here observe, that most of the children of these maritime regions possess a weak and delicate frame, and do not enjoy good health until they have arrived at a mature age. Maniacal diseases are uncommon, and a remarkable exemption takes place from idiocy in most of the populations of the towns previously mentioned; whether children so affected are put to death, as some native doctors have gravely asserted, appears to me very questionable, if applied to this river; probably such may be the case in others.

Chronic ulcers, especially on the lower extremities, are frequent, and well-marked cases of elephantiasis may sometimes be seen in the slaves newly imported from Soudan. These comprehend the outline of the principal maladies that exist in the Rio Formosa and slave coast, but there are others, also endemic to them, to which I shall advert on a future occasion.

From Youngtown seaward, the right, or, as it is denominated, the Boobee side of the river, presents precisely a similar aspect to the one lately described. Shallow indentations and occasional projections of the banks, clothed by young mangrove bushes, with a solitary creek here and there, are the only objects that meet the gaze from the above town to Callear Creek, a distance of ten or twelve miles. This creek nearly faces the one leading to Jacqua, and is of greater magnitude than the others in this part of the stream. It has been supposed to communicate with the Rio Esclaves, as canoes from that river frequently visit the factories by this route. An inconsiderable village, named Battarra, is situated on the left bank, near the entrance, and a remarkable promontory, termed Jo Point, may be observed at its confluence with the river: in the vicinage of the latter is the town of Boobee. Bubie, or Boobee, is now the

principal seaport of the kingdom of Warrée: it is erected on the margin of the mangrove swamps, with a fine sandy beach in front, which also continues down the river to south-east point. It contains a population of seven hundred, who are an indolent and evil-disposed people. A small rivulet separates it from Ullaby, a miserable village, near which are the ruins of an old English factory. Salt-town lies a mile and a half distant, at the mouth of the river opposite north-west point. No mercantile establishment existed in this river before 1786, when the French erected a fort, adjoining one of the villages near its embouchure, which was destroyed by the British cruisers in 1793. It may be necessary to state that the most healthy anchorage for vessels visiting this stream is between the towns of Boobee and Salt-town.

The natives of the Rio Formosa are of Eboe descent, and partake of the same moral and physical traits that distinguish the people of that country. In place of the short muscular figure, thick lips, and flat expanded nose, of the Krooman, they are tall, slim, and more symmetrically moulded, with a skin varying from a light yellow to a dark brown, and a countenance the melancholic expression of which is rather prepossessing than otherwise. Yams, plantains, maize, cassava, various kinds of fruits, fish, fowls, monkeys, goats, &c., prepared with palm oil, and highly seasoned by pepper, comprise the diet on which they uniformly subsist. The beverage in general use is the exuded sap of several palm trees: the *Raphia vinifera* and *Elais guineensis* are those from which it is usually drawn. The liquor thus obtained is allowed to ferment, and hence it obtains those intoxicating powers which render it the favourite drink of all the inhabitants of the Western coast of Africa. It is also much valued for its diuretic properties, and is administered in different modes with other native medicines. The *Cypræa moneta*, or East India cowrie, constitutes the currency of the country.

[To be continued.]

REMARKS ON DR. PATERSON'S APOLOGY.

BY SCRUTATOR.

To the Editor of the Medical Gazette.

SIR,

THE members of the medical profession will surely be surprised, that in answer to the distinct charges, involving points of character, which ought to be dearest to a physician, Dr. Paterson has offered no defence. I may now, therefore, assume that he has been guilty of practising a gross deception, suppressing letters, and of various wilful misstatements. He has been arraigned before his profession for these deeds, and his justification is, that he had formed a bad opinion of the candour of the person with whom he had a dispute about a corpus luteum. "I feel," says Dr. Paterson, "that I owe a statement by way of apology, to my professional brethren, for the means which I adopted to procure the delivery of a candid opinion on the preparation in dispute, from Dr. Lee. For the following reasons I considered myself justified in having recourse to a plan with Dr. Lee, that I never would have had recourse to with any other member of the profession."

It would have been difficult to imagine, without the evidence of the fact, that any person possessing the education of a physician, and the station of a professional man, could have written in the above manner. Let me put this apology of Dr. Paterson clearly. His opponent was once guilty of theft; therefore he assumes the privilege of committing murder. Really, sir, the logic would be ridiculous, were not the conclusion monstrous. Such a defence might be applauded among mohocks, but in what atmosphere has the Doctor lived, that he should dare to insult us with his arrant trilling? Himself accused, he becomes accuser! He has neither the discretion to feel that he should defend himself against the strong evidence of facts, nor the delicacy to know that until he has purged himself of the stain of these grave charges, no accusation of his can attack the character of a respectable man.—I remain, sir,

Your obedient servant,

SCRUTATOR.

February 18, 1845.

ANALYSES AND NOTICES OF BOOKS.

“L'auteur se tue à allonger ce que le lecteur se tue à abrégé.”—D'ALEMBERT.

Practical Observations and Suggestions in Medicine. By MARSHALL HALL, M.D. F.R.S. L. and E. &c. &c. Churchill. 1845.

DR. HALL informs us that he has published these “Practical Observations and Suggestions” in an *unpretending* form; 1st, that they may appear in the *modest* manner becoming such a trifle; and 2dly, that they may be readily portable:” for his ambition is, “that they may become the companion of the student, and of the country practitioner, in some of his lonely drives, especially of those whose time is too much taken up by practice to admit of their reading larger and denser volumes.” After a eulogistic chronicle of his labours, the Doctor proceeds to discuss in proper spirit two systems of quackery which have recently occupied the public attention—homœopathy and hydropathy. The former is, indeed, “the art of amusing the patient whilst nature cures the disease:” the latter possesses great power. It may be compared to gambling when the stakes are high. The various profuse applications of cold water, internally and externally, which this system embraces, are measures which may be fraught with good and evil; and if scientific and honourable physicians had taken up the subject in the way of careful and philosophical investigation, much benefit might have been conferred on mankind by its means.

“But hydropathy is a system which comprehends various most powerful agents: the profuse ingurgitation of cold water, the violent affusion of cold

water, lotions of cold water applied over extensive surfaces, &c. These agents are combined and applied to patients whose diseases are equally complicated. Has this problem—To what special cases is each of these powerful remedies adapted?—been solved with all the care and attention so momentous a problem, big with life and death, health and disease, good and evil, demands? Who of our hydropathists is capable of solving such a problem, or has given a tithe of the time to the subject which the solution of such a problem requires?” * * *

“Without a remedy (homœopathy), and in spite of the remedy (hydropathy), patients may, and do, recover. The public then never stop to inquire, but conclude at once, very philosophically of course, that the *post* is *propter*,” p. 12. Again, “if we wish to ascertain the extent of the unaided power of Nature in the cure of disease, let us act fairly and honestly, and try ‘the médecine expectante,’ without attempting to lure, delude, or amuse the weak-minded patient by that absurdity homœopathy, with its infinitely silly, infinitesimally small, doses of medicines. Or if we would really prove the effects of the internal and external use of cold water, let us not begin by hydropathic institutions, but by cautious investigations, following the example of the late Dr. Currie, discreetly using this agent of power for the public good, to the honour of our profession.” p. 13.

We cannot compliment the Doctor for uniform perspicuity of style. The paragraph at the foot of page 18 would be apt to puzzle a practitioner in his lonely rides, especially if the roads were rough, and his nag “a trick of stumbling had.” The following parallel quotations illustrate the *modest* manner:—

“I conclude the present chapter by referring my readers for further information to my ‘New Memoir,’ which contains the latest facts and views on the subject, and by stating that I believe the results of *my* investigations present the key to the diagnosis of the diseases of the nervous system.” p. 24.

“I may be here allowed to refer to my ‘New Memoir’ on this subject, as containing the shortest, yet the most complete, view of this subject.” p. 159.

“I would refer those who wish to prosecute this subject (scarification of the gums) to my work on the ‘Diseases and Derangements of the Nervous System,’ but especially to my ‘New Memoir,’ which contains the most *lucid* and recent view of the whole subject of the physiology and pathology of the true spinal system.” p. 33.

In the remarks on the nature and treatment of stridulous convulsions in

infants, our author, unfolding the same modest manner, states that "the series of cases occurring in the same family, and given in the *Lancet* for April 17th, 1841, and for July the 9th, 1842, *must have excited the deepest interest in the profession!*"

In the succeeding chapters, on the use of setons, curvature of the spine, temperature of the sick-room, apoplexy and paralysis, the practitioner will find various useful suggestions.

For the prevention of milk abscess, and milk fever, the Doctor enjoins depletion of the milk ducts. For this purpose the infant should be put to the breast at the moment it is born. If, in spite of this, the mammae become in the slightest degree tumid, or febrile action be set up, another and a stronger infant should be applied *without delay*. Of course it will be the duty of the accoucheur to provide relays of vigorous suckers under such circumstances. "I do not pretend, in the above proposition, to have advanced any thing new; but in proposing such promptitude, perseverance, energy, and steadiness and decision of purpose, with which I recommend the measure to be adopted, if these be fully apprehended, I believe I do propose something new."

There is a curious chapter on "the temper-disease," from which we transcribe the following:—

"When a child's stomach and bowels are disordered, the temper is fretful; and the same thing is true of older children; so that the natural disposition, however amiable, becomes perverted, and the patient may become a burthen to his family and friends. In all such cases the patient is apt to be blamed, although really to be pitied; though it must be confessed that the perversion of temper might frequently be controlled, and the physician's attempts to relieve might be seconded where they are but too frequently opposed.

"The most frequent, yet the most extraordinary of these perversions of temper, are seen in young females. It is a species of aberration of the intellect, but short of insanity, real enough, but exaggerated, fictitious, factitious, and real at the same time. It frequently has its origin in dyspepsia, hysteria, or other malady, and in emotion of various kinds, such as disappointment, vexation, &c. Its object is frequently to

excite and to maintain a state of active sympathy and attention, for which there is, as it were, a perpetual morbid, and jealous thirst. It was rather aptly designated, by the clever relative of one patient, an *ego-mania*.

"One patient cannot articulate; another cannot walk; a third cannot eat, cannot swallow, or, if deglutition have been performed, does not retain the food on the stomach, but, without nausea, and apparently without effort, returns it, as it were, by an act of easy rumination.

"I think I have known one and the same patient forcibly to retain the contents of the intestines until an enormous tympanitic distension was the consequence; and to retain the urine until the pelvis of the kidney became distended, and the kidney itself enlarged.

"The abdomen of a patient, a malingerer in the hospitals and workhouses, was marked extensively by leeching, cupping, and setons, and it was proposed to extract a supposed diseased ovary, and to this operation the patient pretended to be ready to submit!

"I was consulted in the case of a young lady, who was affected with paroxysms of a violent, apparently spasmodic, action of the muscles which raise the left shoulder, attended by a partial inspiration; the attack usually came on *horâ somni*, and many were the wakeful hours which this affection caused to the patient, her friends, and her nurses. I then suspected, but would not believe, that these muscular actions were voluntary; I now believe they were so.

"In another young lady, a similar apparently spasmodic action, more constant or less in paroxysms, affected the muscles which raised the right thigh. I always regarded this affection as one denoting temper.

"In one patient the fingers were forcibly contracted into the palm of the hand. In other cases there are various forms of lameness. Every one remembers the famous case of Miss Pancourt.

"One young lady was affected with ptosis. Another was unable to write, except in zig-zag forms, a little like the effect of real tremor.

"This affection is not limited to females, or to grown-up persons; an athletic youth of 16 pretended to be affected by paralysis of one lower ex-

tremity. Sir B. Brodie saw him with me, and agreed with me that it was feigned; and our opinion was confirmed by perfect recovery.

"Nor is it confined to adults: one little patient, aged ten, under the influence of jealousy, feigned a regular evening attack of delirium, being frightened at lions, tigers, bears, &c. and at one time could not articulate, and at another could not swallow. A little boy, aged eight, feigned a regular evening attack of spasmodic affection.

"Having thus sketched the case of the temper-disease in general terms, I shall now proceed to describe this singular affection more particularly. I hope not to be mistaken. I do not regard it as entirely a feigned disease. It is, originally at least, the result of malady, or of some mental or bodily affection. It is allied to hysteria; and hysteria—hysterical palpitation, for example—is a real disease. It is best illustrated by the effects of derangement of the stomach and bowels in infants,—and who would think of correcting a child for temper which was the immediate, natural, and inseparable effect of bodily disorder? It is a perversity, an insaniola, originating in bodily disorder or mental affection, and perpetuated by a morbid indulgence of temper, and desire for sympathy and attention.

"In the midst of such a case as this, the last resort—a forlorn hope—has been to homœopathy and mesmerism."

Sterility is a favourite subject with the Doctor, under the name of *aphoria**. He admits that it frequently depends on organic defect; but the fact that a first child has been born after many years of marriage is sufficient proof that in other cases the defect has arisen from causes of a functional and less permanent nature. Taking advantage of the extraordinary sympathy subsisting between the mammæ and the uterus, he recommends, on reflex principles, a robust infant to be repeatedly and perseveringly applied at the return of the catamenial period, in the hope that the secretion of milk may be excited, and the uterine blood diverted from the uterus and directed into the

mammary vessels, and that a change in the uterine system, and a proneness to conception, may be induced. "I would propose, then, that the patient should sleep, for one week before and during each catamenial period, with an infant on her bosom." p. 157.

For prosecuting this ingenious scheme on a large scale, it would be desirable to have a "baby delivery company" established, which would supply lusty sucklings at so much a night. None manifesting any signs of *temper-disease* ought to be issued. We have no doubt the husband would get speedily reconciled to the mewling and puking of the little innocent, buoyed up by the prospect of his wife becoming a joyous mother of children. We only fear that delicate ladies might have their rest seriously disturbed by the struggles of the infant incubus, vainly seeking to allay its thirst at cisterns which hold no milk.

The following cursory remarks on prognosis are not unimportant:—

"The physician is made responsible for every case of sudden dissolution. His only protection is in a most explicit and even repeated prognosis of the event—a thing sometimes impossible.

"No one would prognosticate a sudden dissolution in chlorosis, however inveterate and severe. Yet I have known four examples of a sudden, or rapid, fatal termination in this disease.

"Few physicians would think it necessary to forebode such ill in cases in which profuse blood-letting had been adopted, or profuse hæmorrhage had occurred, if the patient appeared to be, however slowly, convalescent. Yet, in such cases, sudden death has occurred so frequently as not to be a very extraordinary event.

"But the most treacherous cases are those of intestinal obstruction, from various causes. The patient shall have suffered from sickness,—rejecting all food and medicine; and from constipation, resisting every kind of aperient or purgative, however administered, whether swallowed, injected as an enema, or applied to the tongue (croton oil), or externally: at length the bowels shall be moved satisfactorily, and the patient shall appear better in every respect! The appearances are fallacious. The powers of the heart, (so apt to be impressed through the medium of the stomach and bowels)

* A barefaced plagiarism of the substance of Dr. M. Hall's chapter on *Aphoria* will be found in a production that has just appeared, "On the Remedial Influence of Oxygen, or Vital Air," &c. by J. Evans Riadore, M.D. F.L.S.—See p. 80-84.

shall have yielded to the struggle; a state of the most insidious sinking has set in. Food is retained; the bowels are freely moved; all pain is gone; the patient, as I have said, appears better in every respect; but in the course of the night, or in the course of twenty-four hours, sinks and expires! I could not, if it were necessary to do so, describe this painful state of things, whether the feelings of friends or those of the physician be considered.

"In diseases of the head; in diseases of the heart; in diseases of the blood (whether mere anæmia, or that which occurs in asphyxia, diabetes, albuminuria, extreme dyspepsia, &c. &c.); in cases of the exanthemata, especially variola and scarlatina; sudden death occurs. Attacks of epilepsy are sometimes suddenly, sometimes less suddenly fatal. Cholera, dysentery, even diarrhœa, occasionally induce rapid and unexpected sinking. I have already noticed the effect of effectual relief to the bowels after constipation.

"Indeed, the influence of the intestine on the heart is most remarkable; in mere dyspepsia, the nose, ears, hands, and feet, are apt to be cold and livid; one of the most distinctive marks of tuberculous disease in the abdomen is a frequent, small pulse, with still greater lividity and coldness of the nose, ears, hands, and feet; in inflammation of the intestine, the pulse is known to be of remarkable smallness; the same thing is observed in hernia. This subject deserves to be prosecuted further, both in a physiological and pathological point of view.

"In the course of various diseases, the most insidious sinking is apt to occur, and the physician should treasure up any facts which lead to its prompt detection. I shall enumerate several of these:—

"The first is—breathlessness. This is observed when the patient moves about—in walking, or, in acuter cases, even in bed. It is heard by the attentive physician. It is merely what I have termed it—a little audible breathlessness. It occurs in diseases of the heart; in extensive diseases of the lungs; in cases of exhaustion; in cases of debility. It denotes great danger, and almost certain death.

"A second symptom of this kind is—a slight crepitus in the breathing, heard without the stethoscope. The

rattles in bronchitis, or other diseases of the lungs themselves, must be excluded. The crepitus to which I allude comes on in the course of fever, and other diseases of the general system; in extreme exhaustion and debility; in disease in the head or abdomen; as an early symptom of the sinking state.

"A third symptom, frequently conjoined with this crepitus in respiration, is tympanitic tumefaction of the abdomen. Both arise from the same cause—a deficiency and failure of the ganglionic nervous power.

"There is a fourth symptom, which I have observed in puerperal diseases, chiefly, of fearful, if not fatal, tendency: it is a peculiar severe pain in one side of the neck; I know not of what nature; but I have observed it in fatal cases so frequently, as to think it worthy of being thus pressed upon the attention of my medical brethren."

Chapters 29 and 30 contain some interesting pathological observations on gangrene of the face; and Chapter 35 furnishes the details of a case of senile gangrene treated by the nitrate of silver, by Mr. Higginbottom. The subject was a retired tradesman, of full habit, and seventy-three years of age. The third and fourth toes had assumed a dark colour and become a little swelled; and there were two small purple vesications on the lower part of the leg. The disease had existed for several days. The solid nitrate of silver was freely applied over the affected toes and surrounding healthy skin, previously moistened with water, as also over the denuded surfaces of the leg, the vesications having been previously removed. Adherent eschars formed; the inflammation was subdued, and all further mischief prevented. In due time the eschars were thrown off, leaving the parts underneath healthy: no constitutional remedies were employed. The patient lived three years after, without return of the complaint, and died ultimately of old age.

Dr. Hall attacks nævus, most chirurgically, by passing a needle of moderate size, and with cutting edges, through it, so frequently as to induce inflammation with deposit of lymph, and to obliterate and consolidate the vessels of which it is composed without incurring any risk of danger from sloughing. The needle

should be passed in various directions, from one point in the circumference of the nævus to several points more or less opposite. The punctures must be made near the surface in the superficial arterial nævus; but into textures more or less deeply seated in cases of the prominent capillary nævus. The operation needs to be repeated at distinct intervals of two, three, or four months, according to the state of the case, and the progress of the cure. The object of this plan is to avoid pain, hemorrhagy, and scar, and to substitute cicatrix for nævous tissue. Five cases are adduced in corroboration of the safety and efficacy of this mode of treatment. M. Blandin has of late been adopting a congenerous method; with a two-edged tenotome, a subcutaneous puncture is made at a little distance from the growth, and the instrument afterwards freely moved in different directions. Two compresses and a bandage are then applied over the tumor.

Chapter 40 is occupied with the means of preventing insidious diseases of the brain in children. Two cases are given; the first in the shape of an epistolary communication to an M.P. After pointing out various measures of hygiene, the doctor touches upon diet—a little mutton should be taken thrice a day, at breakfast, dinner, and tea; and the vegetable food should consist of stale bread, well-cooked rice, and mealy potatoes. When the bowels are not relieved once daily, a dose of *baume de vie* is to constitute a *chasse-diner*. The medicines recommended are from five to ten drops of steel wine, given in a table-spoonful of water in the midst of meals, alternated monthly with from half a grain to a grain of sulphate of quina, followed subsequently by a course of pale Indian ale. While we formally protest against the system of drugging food, as a general rule, we are not prepared to gainsay that in the skilful hands of an M.P.'s cook, even a *gigot de mouton au vin de fer*, or a *côtelette à la quinine*, may not be a palatable dish.

Tuberculous disease in the abdomen is discussed at some length in Chapter 43. It is, as our author judiciously remarks, the most insidious of all those diseases which may be considered as necessarily and progressively fatal; and is most unequivocally a family or hereditary complaint. Females are

more prone to it than males. It usually occurs from the age of fifteen to that of twenty-five years. It is mainly characterised by three symptoms:—great tendency to coldness and lividity of the extreme parts of the body, a frequent pulse, and slow but progressive emaciation.

“The aspect of the countenance is altogether peculiar, especially in cold weather, together with an obvious emaciation and expression of languor and disease; the end of the nose is livid in colour, and cold to the touch; and there is, in general, either paleness or a slight degree of flushing.

“Similar observations may be made respecting the general surface. There is emaciation; the skin is soft, and apt to become moist; and there are general perspirations during sleep, especially in the early part of the morning; to prevent this perspiration, the patient frequently endeavours to keep awake. There is an undue sensibility to cold observed on the slightest unexpected exposure,—as the opening of a door,—and the patient usually creeps over the fire. Sometimes I have observed the back of the hands and the fore part of the legs to assume a peculiar brown colour, from being burnt by this constant exposure to heat: the hands and fingers are apt to be extremely livid and cold.

“The mode of walking is peculiar, being attended by stooping, weakness, and caution.

“The pulse is always frequent, and generally regular. It is earlier and longer frequent in tuberculous affection of the abdomen, than in that of any other cavity. I have known the pulse to be between one hundred and one hundred and twenty for several years.

“The emaciation in tuberculous disease of the abdomen is uniformly, but very slowly, progressive. It is accompanied by a state of unvaried debility; and, in the later periods of the disease, by some œdema, generally observed more in one leg than the other.

“The other symptoms of this morbid affection are less constant; they are chiefly—an augmented appetite for food; copious, pale, alvine evacuations; and pain, and sometimes a perceptible tumor, in some part of the abdomen, especially in the iliac or

hypogastric regions. The catamenia simply become scanty, or cease, without undergoing the changes observed in some cases of disorder of the general health.

"There are altogether a peculiar appearance of the countenance, a peculiar mode of walking, and a peculiar attitude and manner in general, all denoting debility and great disease; and if to these be added the peculiar sensibility to cold, and tendency to coldness and lividity of the extreme parts of the body, the very gradual emaciation, and the habitual frequency of the pulse, it is scarcely possible to mistake the nature of this disease: but, in practice, the diagnosis requires very careful and minute observation."

The principal causes of this morbid affection are, among the poor, sedentary habits, scanty food, a damp atmosphere, and defective clothing; and, among the rich, warm apartments, reclusive studies, and a variable mode of dressing. The chief preventives are a nutritious and animal diet, an active and regular system of exercise, warm clothing, sponging the surface, and a strict attention to the general health.

Chapter 46 is devoted to the consideration of certain effects of intestinal irritation, which, although of an acute and alarming nature, have not, according to Dr. Hall, been always understood in practice, or discriminated from some other morbid affections of a totally different nature, and requiring a varied, if not an opposite, mode of treatment.

"The case resembles, in many instances, the most acute phrenitis; and it is this form of the disorder in particular to which I wish to draw the attention of the profession. In other instances, the affection has assumed the character of inflammation of the intestines or peritoneum. Occasionally, the seat and kind of pain have led to the suspicion of pleuritis. Or attacks of palpitation have suggested the idea of disease of the heart.

"Very frequently two or more of these affections take their rise in succession, the first or second probably ceasing entirely before the subsequent one is established—an event which has, I believe, often led to an erroneous idea of the metastasis of inflammation or other morbid affection from one organ to another.

"The attack generally takes place

rather suddenly. It usually begins with severe rigor, which is succeeded by great heat of skin, and eventually by perspiration. With the rigor or heat there is usually the accession of some severe local affection.

"The changes in the course of the disease are, like the first attack, generally sudden. The patient is better and worse, and the most urgent messages are sent at different times to the medical attendant.

"Generally the patient will be found to have been previously subject to disorder of the bowels; afterwards he is apt to experience similar attacks, unless he be attentive to diet and regimen, and to the state of his bowels."

The indications to be kept steadily in view as regards treatment, are, to prevent inflammation, by cautiously bleeding, if necessary; to remove the cause of the affection by free purging; to allay irritation by an ammoniated opiate draught; to obviate exhaustion by nourishment; and to relieve the local affection by cold lotion applied to the head, a liniment to the chest, and a fomentation and liniment to the abdomen, according as the pain occupies one or other of these regions of the body.

Next in order is an essay on the state of sinking from various causes, which will repay perusal. It embodies the views of Mr. Hunter and Sir H. Hallford on the subject.

At page 340, an instance of chronic inflammation is detailed, in which impending suffocation was averted by the operation of laryngotomy, and the original disease subsequently removed by mercurial action. By the way, Dr. Hall adduces as a means of diagnosis in laryngitis, that the patient cannot "snuff up;" the volume of air thus admitted into the larynx being insufficient to produce that effect, although its due velocity is not wanting. In this manner, laryngitis, in which there is thickening of the lining membrane of the glottis or larynx, and consequent diminution of this orifice, may be distinguished from tuberculous ulceration of the glottis or larynx, in which, so far from there being diminution, there is augmentation of the orifice.

The concluding chapters are: On the treatment of the atrophy of paralytic limbs, by W. F. Barlow, Esq.; and on the relation of the spinal marrow to parturition, by W. Tyler Smith, M.D.

In terminating our notice of these lucubrations, which contain much that is ingenious and useful, though oddly strung together, we would humbly suggest to the eminent author that there is "a call upon mankind to value and esteem those who set a moderate price upon their own merits," or, as Horace finely expresses it :

Quanto quisque sibi plura negaverit,
A Diis plura feret. —

On determining the quantity of Arsenic, and at the same time obviating the inconveniences encountered, with MARSH'S apparatus.

It is well known that fluids mixed with glutinous matter are very liable to froth up when hydrogen is disengaged in them from the mutual action of zinc and a dilute acid; and that the froth obstructs the due performance of the experiment of Marsh. It is equally known, that much of the arsenic contained in the poisonous liquid so tested, escapes condensation and eludes measurement. A committee, appointed by the Prussian Government, have contrived an ingenious modification of that apparatus, which may be simplified into the annexed form—

A, is a narrow glass cylinder, open at top, about 10 inches high, and $1\frac{1}{4}$ or $1\frac{1}{2}$ inch diameter inside; B, is a glass

tube, about 1 inch diameter outside, drawn to a point at bottom, and shut with a cork at top. Through the centre of this cork, the small tube C passes down air-tight, and is furnished at top with a stop-cock, into which the bent small tube of glass (without lead) E is cemented. The bent tube F is joined to the end of E with a collar of caoutchouc, or a perforated cork, which will be found more convenient.

The manner of using this apparatus is as follows:—Introduce a few oblong slips of zinc, free from arsenic, into B, and then insert its air-tight cork with the attached tubes. Having opened the stop-cock, pour into A as much of the suspected liquid, acidulated with dilute hydrochloric or sulphuric acid (each pure) as will rise to the top of the cork, after B is full, and immediately shut the stop-cock. The generated hydrogen will force down the liquid out of the lower orifice of B into A, and raise the level of it above the cork. The extremity of the tube F being dipped beneath the surface of a weak solution of nitrate of silver, and a spirit flame being placed a little to the left of the letter E, the stop-cock is then to be slightly opened, so that the gas which now fills the tube B may escape so slowly as to pass off in separate small bubbles through the silver solution. By this means the whole of the arsenic contained in the arseniuretted hydrogen will be deposited either in the metallic state upon the inside of the tube E, or with the silver into the characteristic black powder. The first charge of gas in B being expended, the stop-cock is to be shut, till the liquid be again expelled from it by a fresh disengagement of hydrogen. The ring of metallic arsenic deposited beyond E may be chased onwards by placing another flame under it, and thereby formed into an oblong brilliant steel-like mirror. It is evident, that by the patient use of this apparatus the whole arsenic in any poisonous liquid may be collected, weighed, and subjected to every kind of chemical verification. If F be joined to E by means of a perforated cork, it may readily be turned about, and its taper point raised into a position such as when the hydrogen issuing from it is kindled, the flame may be made to play upon a surface of glass or porcelain, in order to produce the arsenical mirror.

A Treatise on Corns, Bunions, the Diseases of Nails, and the General Management of the Feet. By LEWIS DURLACHER, Surgeon Chiropodist (by special appointment) to the Queen. Simpkin and Co. 1845. Svo. pp. 196.

In this stage of society the chiropodist is as essential and acknowledged a character as any other special practitioner, and if the public are somewhat niggardly in awarding him a rank above his handiwork, they are no doubt proportionably liberal in their compensation, for, according to Adam Smith, crafts which are reckoned less reputable have higher money wages.

The author tells us he has endeavoured in the present work to communicate the result of nearly thirty years' practical experience in the diseases of the feet. To two species of those growths which so materially interfere with locomotive comfort, he has given the names of "vascular excrescence" and "neuro-vascular corn." The diseases of the nails are also considered, and directions given for the treatment, both palliative and curative, of that troublesome affection, "the nail growing into the flesh." Copious instructions are contained in a succeeding chapter, touching the general management of the feet, which even cardinals aspiring to the papal chair might profitably study. The topical remedies upon which Mr. Durlacher relies, are, nitrate of silver, cold water, spirit lotions, and soap plaster. There are six coloured plates appended, which represent certain of the above ailments under a very formidable aspect. We conclude by declaring we should not hesitate to submit our toes to his operative skill, if ever pinched by neuro-vascular or other corns.

MEDICAL GAZETTE.

Friday, February 28, 1845.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

THE NEW BILL.

THE bill for the better regulation of medical practice throughout the United

Kingdom passed the first reading on the 25th current, and is to be read a second time on the 7th of April.

We congratulate Sir James Graham on the calm, able, and dispassionate manner in which he has dealt with this intricate subject. The whole tone of his speech, indeed, is one of conciliation towards all parties.

While certain very important amendments are introduced, some of the main provisions of the draught formerly submitted to Parliament are very judiciously retained in the present bill. The first of these is the establishment of a Council of Health, which shall have the superintendence and control over medical and surgical education, and which shall constitute a Board, the seat of which is to be in the metropolis, so as to be easy of access to the executive government, in order to assist in advising upon all questions affecting the health of the people at large; such as endemic and epidemic diseases. The second object which this measure is intended to effect is the abolishment of all monopolies in the medical profession, and to secure to all practitioners equal facilities of practice, as well as to afford a guarantee to the public of equality of attainments on the part of medical men. The chief end of legislation in such matters we have always maintained to be the protection of the public. Nor is this lost sight of; for whilst, on the one hand, equality of practice is conceded to the profession, on the other, equality of attainments is secured to the public. By the law as it will in future stand, no title to practise in the three kingdoms shall be granted in any one of the branches of medicine or surgery except to persons who have been previously examined before a competent tribunal, and pronounced fully qualified. None but such as have passed this ordeal shall be entitled to registration—a means

whereby their attainments shall be certified and made generally known. We think it highly desirable that the registry should be rendered compulsory.

The above were the leading objects of Sir James Graham's bill of last year, and he pledges himself to have them fully carried out, provided the present measure gains the sanction of parliament.

The proposed alterations are as follows: In the former bill it was contemplated to repeal the statute of Henry VIII. (14 and 15, c. 5), which gives to the members of the College of Physicians the exclusive right of practising in, and within seven miles of, the metropolis. It is not now the intention of the Right Hon. Baronet to repeal that act entirely, but only so far as to exempt from its penalties all physicians who shall be registered according to the provisions of the proposed measure. A clause, moreover, has been framed, whereby the Universities of Oxford and Cambridge will be exempted from its pale, and their graduates consequently confirmed in all their existing privileges. Sir James has found these learned bodies rather refractory as to foregoing their immunities, and, by way of conciliation, has inserted the above clause, whereby their graduates shall be entitled, as before, to practise according to their respective degrees throughout all England and Wales, save and except in the metropolis, and within seven miles of it. This provision will be certainly made in the proposed bill, unless the aforesaid Universities agree to come under its operation. We sincerely trust they will not hold out, if they mean their members to rank as registered practitioners, and to participate in the administration of the Council of Health.

To obviate all difficulty meanwhile, a particular arrangement has been

made between the College of Physicians and the Universities. An assessor is to be sent from thence to Oxford or Cambridge, who shall have the power of granting medical degrees in conjunction with these bodies, which shall confer upon their graduates the right of practising within the liberties of the College, if we may use the expression.

Sir James Graham has come to the conclusion, that it is not expedient to repeal the Apothecaries' Act in totality, but only in so far as parties who shall be registered under the proposed bill are concerned. The full exercise of the power to enforce penalties is to be left untouched. Hence the Apothecaries' Company will still be allowed to prosecute all unregistered practitioners, and all persons venturing to practise without holding their license.

An additional restraint, moreover, is to be imposed, which shall make it penal for any unqualified individual to assume the title of physician, of surgeon, or of apothecary, or any other title recognized by the bill. This clause is couched in the following terms:—

“And be it enacted, that every unregistered person who shall wilfully and falsely pretend to be, or take or use the name or title of physician, doctor, bachelor, or inceptor in the faculty of medicine, or surgeon, or licentiate in medicine and surgery, or apothecary, or any name, title, or addition, implying that he is registered by this act, or recognized by law as a medical or surgical practitioner, shall be deemed guilty of a misdemeanor in England and Ireland, and in Scotland of a crime and offence, and being convicted thereof, shall be punished by fine or imprisonment, or both, as the court before which he shall be convicted shall award*.”

This is obviously intended as a stringent means of protection for the public

* Times of Feb. 26.

and the profession against ignorant and unqualified pretenders.

It is further proposed to repeal that portion of the Apothecaries' Act which requires the examiners—who will henceforth be associated with physicians in the examination of the licentiates in medicine—to be members of a civic guild, the admission to which may be by purchase or inheritance, without any medical knowledge, or test of fitness. The qualification for an examiner shall be in future, that he is an apothecary of ten years' standing in practice, or a licentiate in medicine of the same standing; anticipating that after the lapse of ten years the examiners will be, in fact, licentiates in medicine under this act, and that under the general name of "licentiates" they will be general practitioners.

Sir James Graham expressed his earnest desire to have seen one common examination established for all men entering the profession, leaving it to the choice of each to take up the branch of surgery, or that of physic, according as it may suit either his studies or his peculiar ideas or wishes. To this plan objections have been raised which appear both reasonable and insuperable. The College of Physicians has always attached great importance to an University education; therefore, to enforce upon persons who have received that education such an examination as would be demanded of others at an earlier period, would greatly increase the protracted study of the physician, who is not to be eligible to practise till he is twenty-six years of age, by the new regulation. This objection, however, does not apply to surgeons; it is therefore provided that none shall be qualified as such till he is twenty-five years old, or unless he shall have been previously examined, and duly passed, as a licentiate in surgery and medicine.

Midwifery is to form a distinct object

of examination, and to be specified in the registration.

The Right Hon. Baronet doubts whether good would be done, or the honour and station of the general practitioners advanced, by dissolving the connection between them and the College of Surgeons, and giving them an institution of their own. He tells them they will have an opportunity of considering the changes now made, and of reviewing the requisition they have presented for a charter of incorporation, and that he will be delighted if the result shall prove a withdrawal of that requisition, and consequently a closer alliance with the College—

"A great and noble institution, which, with all its defects, has produced some of the most eminent and best surgeons in Europe; which possesses at this moment the finest museum in Europe, and, as a visitor, I may assert, one of the most renowned collections in physiology*."

He would not now anticipate a discussion on the recent charter granted to the College of Surgeons—that there are defects in it he is fully aware, but when he introduced for the first time a particular order into that body, which existed in every other College in England, Scotland, and Ireland, namely, the order of Fellows, it was necessary that a constituency should be created for the election of the Council.

Sir James Graham observes it was an obvious error in the bill of last session to ordain that a gentleman seeking to be qualified as a physician, should for the two years immediately preceding his examination at the College of Physicians have resided in the University. In many instances this would be found a great hindrance to education in a foreign country. It is therefore proposed to change the condition to two years' residence at the University, after matriculation, instead of two years before examination. With respect to at-

* Speech in Parliament.

tendance on foreign universities, it is deemed expedient to enjoin only one year's residence, out of the whole term of studies, which is three years.

The power of nominating permanently the Council of Health might be most safely left to the executive government, acting on its own responsibility in Parliament. But, as a mixed scheme of nomination and election has been proposed, the Home Secretary is inclined to abide by the provision introduced in the former Bill. In reserving to the Crown the nomination of six members of the Council, it is meant that a portion, at least, must be general practitioners, including country practitioners.

Among the omissions in the other bill, no power was given to the Council to remove a person from the register in case of flagrant misconduct. It is now intended to invest the Council with authority to remove from the register all parties who may be convicted in a court of law of any criminal offence, or who shall have used any false, or simulated testimonials, to obtain admission.

Another alteration is to be made, on the ground of misconception. It was proposed to give the faculty of physicians and surgeons of Glasgow equal power of licensing with the faculty of physicians and surgeons of Edinburgh. The proposition was made in the belief that the faculty of Glasgow had in the four counties adjacent to that city power to license practitioners both in surgery and in medicine; but the question has been directly raised, and it has been determined that they have no such power so far as medicine is concerned. The sole power is therefore to be entrusted to the Colleges of Physicians and Surgeons in Edinburgh.

Leave having been given to bring in the bill, Sir James Graham next moved for leave to introduce a bill for four new charters to be granted to the Col-

leges of Physicians in London, Dublin, and Edinburgh, and to the College of Surgeons in Edinburgh, which he said would serve to render more efficient the operation of the above measure. So far from rendering these bodies more close, the intended charters will render them more open.

MORTALITY OF THE METROPOLIS.

Deaths from all causes registered in the week ending Saturday, Feb. 15.

ALL CAUSES.....	1112
SPECIFIED CAUSES.....	1110
I.—Zymotic (Epidemic, Endemic, and Contagious) Diseases, 178; among which, of—	
Small Pox	33
Measles	19
Scarlatina	38
Whooping Cough	29
Croup	7
Thrush	8
Diarrhoea	9
Dysentery	0
Cholera	0
Influenza	3
Typhus	25
II.—Dropsy, Cancer, and other Diseases of uncertain or variable Seat 120; among which, of—	
Inflammation	0
Dropsy	38
Scrophula	3
Cancer	17
Atrophy	10

OF
Medicine and the Collateral Sciences.

FRIDAY, MARCH 7, 1845.

CASES TREATED IN THE WEST-
MINSTER HOSPITAL.

With Clinical Remarks,

BY BENJAMIN PHILLIPS, F.R.S.
Assistant Surgeon.

Eczema treated by arsenic and warm water.

W. K., aged 49, was admitted into St. Mark's Ward, under the care of Mr. White, suffering from eczema in an aggravated form. For six years it had affected the left leg and thigh. The limb was hypertrophied, so as to have a slight resemblance to the Barbadoes leg, and the surface was intersected in all directions by deep fissures. A variety of plans of treatment had been employed in the case, but beyond a passing relief they had done no good.

Ordered to take Hyd. Chlor. gr. v., Jalap gr. xv., twice, with two days' interval. To have the affected limb bandaged, to have the bandages wet with warm water, and covered with oiled silk, so as to constitute a constant tepid bath, and to take Liquor Arsenicalis, minim. v. bis die.

Under this treatment, in three weeks the integument had become soft and smooth, and in six weeks he was discharged cured.

A. R., aged 24, was admitted as an outpatient under the care of Mr. Phillips. Both his arms, from the shoulder to the wrists, were affected with eczema in a form little less aggravated than the last case, but not of such long standing. He was treated in the same way, and the good effect of the topical treatment was made very evident. He applied the wet cloths to the whole arm, but the oiled silk was not kept on above the elbow. In a fortnight the skin below the elbow became soft and natural; that above the elbow continued harsh, though much improved. In a month from the commencement of the treatment this severe affection was completely got the better of.

901.—xxxv.

REMARKS.—This simple plan of treating that extremely intractable form of skin-disease, chronic eczema, Mr. Phillips has followed with signal success in many cases. No case could have subjected it to a severer trial than the first. It was of six years' standing, the skin was greatly thickened and hardened, and it was intersected in all directions by deep fissures. It had been treated by various methods, with passing, but very temporary relief. It completely yielded to the above treatment, and within four weeks from its commencement the skin was as soft and as natural as that on any part of his body. He did not leave the hospital for a fortnight after the cure, in order to be assured that it was complete.

Strangulated hernia—Operation.

A. R., aged 52, and suffering from strangulated hernia, was admitted into Northumberland Ward, Dec. 20th, under the care of Mr. White. Soon after his admission he was seen by Mr. Phillips, who obtained from him the following history of his case. In 1829, while making a powerful effort, a portion of gut descended in each inguinal region. It was soon returned, and maintained reduced by a double truss. On many occasions it has escaped, but usually he has returned it himself. In several instances much difficulty has been experienced, and he has resorted to the hospital, where relief has been obtained. At present there is a large tumor on each side, extending to the scrotum. Considerable attempts have been made to reduce them; on the right side they have been successful, on the left they have failed. There is no abdominal tenderness, or constitutional irritation; but there is some nausea, with a clean tongue.

To be placed in a hot bath; to have the taxis applied; and, if those means fail, when taken out, to have ice applied to the tumor, to have Hyd. Chlor. gr. vj., and to have a castor-oil injection.

2 X

21st.—Those means failed; but the tumor is certainly smaller than it was yesterday. In other respects no change.

To have a large castor-oil injection every six hours. Ext. Coloc. Comp. gr. iij.; Ol. Carui. Gutt. ss. 4tis horis.

22d.—No relief. There is more sickness; the stomach has become irritable, but the tongue is clean; a slight tenderness over the lower part of the abdomen on the left side. Complains of want of sleep, but no general excitement.

To have the following enema every six hours: Sp. Tereb. ʒiij.; Ol. Ricini, ʒiss.; Liqueur Potassæ, ʒj. Turpentine fomentations to the abdomen, and Opil gr. j. at bed-time.

23d.—No material change. Sickness continues, and he is much inconvenienced by flatus.

To have Magnesie Sulph. ʒj., Aq. Carui, ʒj. every hour. A pill containing Ol. Rutæ, gtt. j. occasionally.

24th.—No very obvious change in the symptoms since yesterday; sickness still persists, but the flatus is less troublesome; the tongue is rather more coated; there is a slight increase of fulness and tenderness over the abdomen; pulse 86.

To persist with the aperient for the present; to have a common cathartic enema; to continue the turpentine fomentation.

25th.—This morning, soon after eight o'clock, he complained of more severe griping pain, which was soon followed by fecal vomiting. Between one and two o'clock, a consultation was held, and the operation decided on, because all means of acting on the bowels had failed, and because the symptoms were become more urgent. Even at this time the countenance was perfectly placid, the tongue moist, the pulse 84, the peritoneal tenderness not great, and the abdomen little distended.

The operation was performed by Mr. Phillips. A single incision, between five and six inches long, was made; it extended from above the neck of the sac to the lower part of the scrotum; the sac was soon exposed, and looked almost as strong as the aponeurosis of the external abdominal muscle. It was opened to the extent of nearly four inches, but there was scarcely any fluid in it except at its most depending point. The intestine was now exposed; it was very rough, and very dark from congestion, and it was evident that it would not bear much manipulation, but its condition was still not too bad to justify its return into the abdo-

men. The stricture at the neck of the sac was relieved so that the finger could be passed through the ring into the abdomen; although there was apparently ample room, there was much difficulty in inducing the intestine to return, so much so, as to give reason to think that there were adhesions, but, after very careful patient manipulation, it was returned.

10 o'clock P.M.—During the evening there has been considerable fecal vomiting, but no evacuation from the bowels; countenance still unchanged; pulse 92; some abdominal tenderness and considerable tormina.

To have an enema of a pint of warm water, and 2 oz. of olive oil, and to retain it as long as possible. Turpentine fomentations to the abdomen, and, if the vomiting continue, to have a drop of creosote.

26th, 8½ A.M.—Is much more comfortable; has had three copious evacuations from the bowels; the sickness has ceased, but not until after he had taken the creosote; tongue moist; some thirst; pulse 82; abdominal tenderness less.

9½ P.M.—Complains of sickness; has vomited several times small portions of sour bilious matter; tenderness a little increased; pulse 84.

To repeat the enema and turpentine fomentations, and to have Potassæ Bicarb. gr. x.; Acidi Hydrocyanic. ʒiij., occasionally.

27th, 9 A.M.—The bowels have acted freely, the tormina is lessened, there is some peritoneal tenderness, the tongue is somewhat loaded, the pulse is 80, and the stomach quieter.

To continue the fomentation, and, if there be much griping, the olive-oil injection to be thrown up at night.

28th.—Much relief was experienced from the injection; it remained up some time, and was followed by a copious stool. The wound is nearly healed by first intention.

29th.—He is in a more satisfactory state, but the tongue is coated. No stool since the night before last.

30th.—He complains of soreness about the wound, and a feeling as if "something had given way" while coughing. The wound is gaping, and a black sloughy-looking substance is apparent. The sutures are cut, the wound immediately opens to nearly its whole extent, when the black mass is found to be a large clot of blood in the course of breaking down.

Warm water dressing to be applied, and the olive oil injection to be administered.

31st.—He is very low; the edges of the wound have an erysipelatous redness; the bowels were relieved.

To have a mixture of Acet. Ammon. with excess of Ammonia, and 4 oz. of wine; to have a poultice over the dressing.

Under this plan he gradually recovered, and was discharged, at his own request, with a small sinus, which is now healed.

REMARKS.—The interest of this case appears to be comprised in the fact, that strangulation was so fully developed in a middle-aged person without occasioning any very pressing symptoms. The pulse did not exceed 86; the tongue was comparatively clean; there was little abdominal tenderness, and the countenance was free from anxiety, although near ten inches of intestine was under strangulation; still there were two capital facts present during five days—sickness of the stomach, and obstinate constipation.

The reason for this comparative absence of urgent symptoms is to be found in the circumstance that it was an old hernia, that there was a large ring, and that for some days the stricture upon the intestine was not close. It is true it was close enough to prevent the free return of venous blood, and ultimately to cause so much tumefaction of the intestine itself that the stricture then became a close one, and the necessity for operation urgent, although starving and ice were well followed up.

After the gut was liberated it suffered nothing to pass the protruded part for many hours, and the faecal vomiting continued. It was not until the emollient injection had remained some time in the intestine that stools were procured, and, even then, when the great quantity of cathartic medicine got vent, there was no profuse action.

On the third day, the external wound appeared to be nearly healed by first intention; on the fifth, it shewed signs of opening again, and the patient began to flag. On the sixth, the wound looked unhealthy, and an erysipelatous blush surrounded it.

Although there was still some abdominal tenderness, and a somewhat loaded tongue, it was necessary to give support, and that largely, under which he rapidly improved, and on the 27th day the wound had nearly healed.

OBSERVATIONS

ON THE

NATURE AND TREATMENT OF THE MORE IMPORTANT DISEASES OF THE NERVOUS SYSTEM:

With Illustrative Cases.

By EDWARD BLACKMORE, M.D. Edinb.
Member Extraordinary of the Royal Medical Society of Edinburgh, and Physician to the Bath Penitentiary.

[Continued from page 704.]

SECT. IV.—ON EPILEPSY.

SOME of its peculiar phenomena are highly interesting; such as (*a*) its singular feature, which distinguishes it from apoplexy, that the coma should go off entirely of itself, even when the disease is so severe as for the fits to be occasionally repeated ten or twenty times in a day: (*b*) that even when it has been congenital, or has existed from early childhood, it should persist through a prolonged life without much disturbance of the general health, or of the mental faculties: (*c*) that sometimes, when acquired in adult age, it passes into a periodical and purely spasmodic disease, the comatose part of the affection having subsided: (*d*) and that in some cases, after having become an established habit for many years, even after puberty, it entirely wears itself out.

It sometimes, yet astonishingly seldom, leads to palsy of the hemiplegic form. When it has become habitual, and its fits increasingly frequent, it is very likely to end in fatal apoplexy. When properly treated before the age of puberty, it is often cured; and even when acquired after puberty, and become habitual for years: but when it appears in early childhood, and persists to adult age, it is very seldom cured.

It is apt to induce a fatuous appearance of the countenance, but this is not always attended with a corresponding degree of mental imbecility.

"Will it recur?" is often a most anxious inquiry on its first appearing. There is generally much danger of its becoming habitual; yet even severe epilepsy has occurred once, and then entirely disappeared. If the exciting cause is recent, and not inevitable, if the head does not show irregular ossification, and if there is no family pre-

disposition, strong hope may be entertained of its non-recurrence if proper precautions are taken. Probably no other disease is so dependent for its recurrence on the habits and physical circumstances of the patient.

The immediate event of the fit is an equally anxious subject: it is very difficult, on the first occasion, to distinguish the coma of epilepsy, which tends of itself to pass away, from apoplexy connected with convulsions; the cases popularly styled "convulsions" in children are really often apoplectic; an accurate diagnosis may, however, be formed by considering the character of the spasms, of the breathing, and of the pulse, with the duration of the stupor. When consequent on other diseases, the prognosis is more serious than in the simple and primary affection; yet even when succeeding to apoplexy itself it is not incurable. Recovery is seen in young subjects, although coma has continued for eight hours, and after the vital functions have begun to fail. Hope is to be founded more on the nature of the predisposing and exciting causes than on the actual symptoms of the paroxysm.

The proximate seat of the irritation is the corpora striata, the medulla oblongata, and the encephalic portion of the spinal chord; and this irritation is often the effect of disease in other portions of the encephalon, the influence of which in inflicting pressure on the basal parts is easily understood from the structure of the head. Various cases show, indeed, that disease in the same remote portion of the brain may occasion either apoplexy, or hemiplegia, or epilepsy; the same sort or degree of influence is therefore not always communicated to the medulla oblongata and spinal chord; or, according to modern anatomical views, the cause of the difference in the effect is, that in epilepsy the organic portion of the spinal chord is irritable as well as the sensorium, and not in the hemiplegic or apoplectic cases; and in the former disease, also, the nervous origin of motor power is more affected than that of the sensorial functions.

The morbid appearances are, (a) a general enlargement of the arteries and veins, with fulness of blood; (b) sometimes a general softening of the brain; (c) an encysted abscess in the hemispheres, or suppuration at the crura

cerebelli; (d) induration and tubercles; (e) exostosis of the interior of the skull.

The most constant, and, in a practical view, the most important, condition which may be regarded as the proximate cause of epilepsy, is excited circulation in the encephalon: this state is either transient or more prolonged, and constituting an inflammatory condition, of which the convulsions are sometimes the first symptom. It is also primary and idiopathic, or symptomatic and secondary on irritation in other organs, particularly the gums and intestines in children, and the uterus and nerves external to the head in the adult. Confirmed habitual epilepsy has probably always its origin within the head.

Morbid congestion in general is spoken of as active or passive, *i. e.* attended with high action of the vessels, or with atony and inirritability.

It is doubtful whether the latter is ever the immediate exciting cause of the epileptic paroxysm; the analogy of convulsions in syncope from loss of blood might appear to favour an affirmative opinion, some pathologists maintaining that even blood-letting to excess makes congestion in the head; but whether this be true or not, convulsive syncope is not epilepsy.

Nor does a bloodless state of the brain ever seem to be the immediate cause of the fit. The predisposition is certainly connected in some cases with deficiency or poverty of the blood in a debilitated constitution—a weak nervous system being very liable to suffer from external irritants, and the weak-vessels being easily dilated by the distending force of the accumulated blood in them, lose their contractile power, and thus a state of passive congestion is habitually maintained in the head. This view of one variety of the predisposing causes is confirmed by the morbid appearances, and by the success of those remedies in the intervals of the fits which restore the contractile power of the vessels, and thus lessen their engorgement.

The invasion of the paroxysm, when supervening on exhausting diseases, or in weak constitutions, appears to be referrible to the same proximate cause—a fulness of blood in the brain, with strong action of its vessels; an action strong, if not absolutely, yet relatively, to the general powers of the vascular

system, in the individual patient, and by which the momentum of the encephalic circulation is for the time increased.

The predisposition is seen under the form of debility and impoverished blood, as above mentioned, and also under that of plethora and strength of constitution. It presents itself, in both its forms, in connection with a scrofulous constitution: its relation to a gouty habit is not so common. It is, in some cases, congenital and unalterable. The principal fixed elements of the predisposition are an enlargement of the vessels of the head; an irregular and protuberant ossification of the skull, with sometimes a deposition of osseous matter in the membranes; and hypertrophy of the brain itself. Of the variable elements of the predisposition, that of a loss of contractile power, with extreme dilatation of the vessels, appears to be the more important, and is more intimately connected with the chronic and habitual epilepsy.

The treatment of Epilepsy.

In all cases, in the paroxysm, either with turgescence of the vessels of the head, or with pallidness and coldness of the face, in the delicate and in the robust, in the recent and in the confirmed disease, the cold affusion is probably the most successful remedy; if then bleeding is practised, it should certainly be to a far less extent than in apoplexy; when excessive, it has only been the means of substituting one form of convulsions for another, or of inducing worse consequences. In that form of disease from a stroke of lightning, or a sun-stroke, or from a large quantity of spirituous liquors taken at a draught, experience shows that the best treatment consists of the cold affusion, followed by an emetic and ammonia, as soon as the power of swallowing has been recovered: bleeding in some such cases has been fatal. Besides the cold dash, a clyster of turpentine is alone required in most cases. Compression of the carotids also has been found useful.

In the intervals of the fits, the most generally curative treatment, in a vast number of cases which I have seen in public and private practice, has been the antiphlogistic, either evacuant or sedative. Small bleedings and cupping, shortly before the period of the

return of the paroxysms, have had a most salutary effect, while profuse bleeding has served to make the returns more frequent. In Case VII., under apoplexy, the good effect of scarifying the head is strikingly seen.

Purgatives are especially valuable; *e. g.* claterium and croton-oil. I have given, also, with good effect, a scrupulous dose of calomel; and in relaxed habits a combination of colocynth with the gum-resin of Cornel has succeeded well. The oil of turpentine is a most useful adjunct in these cases to castor-oil.

Emetics, particularly sea-sickness, have appeared safe and wholesome. Drains, such as the issue by incision on the occiput, are of unquestionable utility in most cases.

Sedatives, as colchicum and digitalis, have been often successful; and, when incautiously given, productive of equal mischief. The extent to which the latter drug is sometimes used deserves reprobation. The refrigerant sedatives, and the shower-bath, deserve more commendation; and as a means of keeping the head cool by night, the air-pillow is not contemptible. Terror is a sedative not easily managed.

In many cases of chronic epilepsy, on the other hand, the most successful treatment is not evacuant or sedative, but tonic—not that tonic plan which fills the vessels with blood, but that which increases their contraction, and equalises the general circulation. Of this class, the more successful, in my experience, is turpentine, in small and frequent doses: the sulphates of copper and of zinc, and the nitrate of silver, appear to act similarly to turpentine, but not so efficaciously.

When the fits have usually recurred in the night, the habit has been broken by an opiate at bed-time, and by the patient being awakened and leaving the bed.

Concubitus rite et legitime peractus has proved a remedy, just as its abuse has been one of the worst excitants of the malady.

CASE XXXV.—An unmarried female, aged 27, during the seven months preceding April 1827, was affected with epilepsy during the night season; the fits returned every fortnight, and were worse shortly before the menstrual periods; she had complained of severe pain in the head, vertigo, and occa-

sional delirium, before the convulsions were established. The fits usually began with the aura epileptica at the epigastrium; much urine was passed in the fits, the sleep profound after them. Her ordinary sleep was disturbed by frightful dreams. She had often, also, hysterical spasms in the throat; the bowels costive; the tongue white.

Croton-oil and Liquor of Potass.

These medicines purged strongly, and an ascaris was voided. After this the head felt better, and she passed a menstrual period without a fit. She then suffered from leucorrhœa, for which alum was given. At the end of a month the epilepsy and vertigo returned, and was connected with costiveness.

Croton-oil repeated, and a perpetual blister.

About May 19th, it was learned that the fits returned in sleep, although the blister had been discharging for three weeks. The general health was good. One drachm of oil of turpentine was then given daily, and exercise enjoined. She then escaped the fits for a month, while taking half a drachm of the turpentine daily, which made slight stupor; after which, being better, she ceased to apply for medical aid.

CASE XXXVI.—A baker, aged 26, in August 1827, after being worn down by hard work and exposure to the heat of the oven, got a second attack of epilepsy, for which he was bled at three times to three pounds within a fortnight. Afterwards, I saw him in an exhausted state, with a threatening of idiotcy, and complaining of severe nocturnal pains in the forehead; the pulse slow and empty. He was quickly relieved by oil of turpentine, ammonia, and tincture of rhubarb.

In February 1828, he came again under my care, having been ill for ten days of vertigo and severe pain at the heart in paroxysms of two hours, threatening syncope; his manner was stupified, and he was slow in answering questions; pulse 60; bowels very costive.

Leeches to the head, a blister on the neck, and croton-oil daily.

The oil vomited and purged, after which he had no return of the symptoms; and by continuing purgatives he was completely relieved.

In May 1829, he again suffered from

pain in the head, and costiveness, with a full pulse; and was again cured by purgatives.

CASE XXXVII.—A female, aged 28, had had epilepsy since she was seven years old, and had been bled occasionally for it. When seen by me, the fits returned every month; tongue white; pulse small; habit costive.

Purgatives and oil of turpentine ordered.

At the end of two months she had had no fit, and felt much better.

CASE XXXVIII.—A boy, aged 14, in March 1830, had two epileptic fits, which disappeared until the end of May, when he was affected with a sudden falling down, attended by deep sleep, and foaming at the mouth, but without spasms.

June 4th.—Pain at the forehead; manner stupid; eyes fixed at times.

Head shaven; bleeding to ten ounces; mercurial purgatives and salines.

6th.—Headache and vertigo; no fever; pulse slow and tense; senses good; tongue white; bowels purged.

A blister and cold to the head; rhubarb and magnesia.

10th.—An epileptic fit from exposure to the sun; pulse slow and irregular.

Leeches, and cold affusion.

11th.—Pulse 58.

Purgatives, assafoetida, and a turpentine clyster.

13th.—A feeling of a choking in the throat, and of a ball rising there; pulse still slow, tense, and irregular.

Purgatives.

15th.—Great relief after a purging of green mucous stools.

Purgatives continued.

On the five following days he had strong fits of involuntary laughter. Sleep lethargic; tongue white; pulse 70; bowels well purged.

23d.—Spasms of the eyelids. In other respects better.

26th.—Pain in the region of the spine the only complaint. He was then cupped, and quickly cured.

Case IX. placed under apoplexy well illustrates the condition of the encephalon by which every remedy is frustrated.

Case XIII. shows the relations of epilepsy to apoplexy, and simple spasm.

CLASS II. THE SPASMODIC AFFECTIONS.

THE cases subsequently narrated show that tetanus, convulsio, chorea, hysteria, and mania, regarded as generic diseases in a nosological aspect, are connected with states of the organization which, in a pathological regard, are really different: in some cases, or in one stage of a case, the proximate cause is allied to that of an inflammatory and febrile disease; in other cases, or another stage of a case, it is similar to that of a purely nervous affection, the internal physical character of which may be either bloodlessness of the part, or a congestion of venous blood.

A most important feature of these affections is the absence of febrile symptoms when the internal state is truly of an inflammatory or highly congestive nature. This fact is impressively shown by the morbid appearances in two of the cases of mania. The pulse is not a fair criterion of the pathological condition of the disease; in some cases of active congestion it is extremely low, both during the spasmodic paroxysms and in the intervals; and in proportion as the congestion is relieved, the symptoms sometimes assume a more febrile character. This feature is particularly to be remarked in many of the cases of tetanus, chorea, and mania. In the early period of all these diseases, it is probable that a state of vascular fulness and increased momentum of the circulation in the brain or spinal chord invariably subsists; and it may subsist even in a very debilitated state of the constitution; and it is often periodical in its recurrence, and that for a very prolonged period.

The cases also shew that symptoms of a truly nervous character, and which arise from a state of the organization the opposite of inflammation, or entonic congestion, may be rapidly succeeded by symptoms that arise from the congestive state. This transition of state is sometimes a source of much embarrassment to the young practitioner. An accurate diagnosis of these pathological conditions is only to be arrived at by earnest attention to the most minute particulars of the symptoms, and of the previous treatment of the case. See Case IX. XVI.

These spasmodic affections are sel-

dom fatal. In chorea, however protracted and severe, the prognosis may generally be cheerful.

A most interesting inquiry is, how far, where there is a family predisposition to insanity, the occurrence of a spasmodic disease may be expected to give immunity from a mental disorder? It appears, so far as my observation has gone, that although epilepsy does pass into mania of the most hopeless character, yet an habitual and purely spasmodic affection does, so long as it continues to recur, tend to keep off insanity.

The treatment—Regarding it as demonstrated by a sound experience that many spasmodic cases which do not exhibit febrile symptoms are to be treated with antiphlogistic remedies, it is also to be observed that, in general, these cases do not bear bleeding to the same extent as purely inflammatory disorders; a single profuse bleeding may either induce the most frightful nervous symptoms, or so depress the vital energies as to lead in a few days to death by syncope. On the other hand, in a subject apparently by no means plethoric, these diseases will sometimes only yield to a full bleeding; and in some cases the effects of a single abstraction of blood are most gratifying: see Case VIII. Cupping seems far preferable to leeches in all the diseases of this class: see Case XIV.

I would urge on the attention of the profession the importance of a remedy which I have lately used several times with gratifying success,—a deep incision of the scalp, and allowing the wound to bleed freely. In spasmodic cases of an encephalic origin, as well as in hemiplegia and mania, when there has been either a fixed pain in the head, or a tender portion of the scalp, so that gentle percussion has induced excessive pain, or a convulsion, or an hysterical fit, my experience, so far as it has gone, has proved that the bleeding from the free incision is a far more powerful remedy than any other mode of depletion. This practice should not be confined, as formerly, to cases of disease in the pericranium, nor should it be adopted merely as a last resource in chronic affections of the brain or its membranes; or as a first step to making the enormous issue lately recommended by some distin-

guished physicians. It would, I believe, be a valuable substitute for leeches and simple arteriotomy in many severe though not protracted cases of head-affections. The relief of headache by the incision, in some of my cases, was so delightful, that "it would be preferred a hundred times to suffering the horrid pain!" The severe extent to which this mode of forming a pea-issue has been carried may bring an important measure into undeserved neglect. A purulent drain, with seventy peas in the scalp, would be intolerable to many persons who would readily submit to a cut three inches in length, and a turpentine dressing followed by an emollient poultice for a few days. My attention was recalled to this measure in the last summer by my late beloved friend, Dr. Abercrombie, who had long used it with great success in cases where, in connection with symptoms of internal disease, a portion of the scalp had become tender. I would submit, however, that it should not be restricted to such a condition, and that it might be extensively adopted as a most efficient means of local bleeding.

The great utility of mercury is strongly shewn in some of the cases of tetanus and chorea; and inunction seems the better mode of using it.

Purgatives cannot be too highly commended. The drastic, however, such as colocynth, will sometimes disappoint the practitioner; it appears, when given in large doses, to produce spasm of the colon, and thus to occasion the retention of feces in its cells. When combined with a very little henbane, or with camphor and soda, its effects are more satisfactory. Aloes, also, by its powerfully emulgent effect on the liver, has conduced to irritation of the intestines, by which the spasmodic disease has been exasperated. The croton oil, and jalap with calomel, generally answer best.

From a few observations I am led to believe that the antispasmodic power of ipecacuanha renders it worthy of more frequent use in these cases than it has obtained. Digitalis, when given incautiously, has often induced alarming nervous symptoms; it might be safely discarded from practice in these diseases. As a sedative, hydrocyanic acid seems far preferable to it.

Counter-irritation, by drains, and the

antimonial ointment, is of undoubted efficacy.

In purely nervous states, cordials in small doses do good; harm, however, seems to have been done by an immoderate use of them. In one case they certainly favoured the occurrence of tetanus; and in another they kept up the periodic recurrence of convulsions.

The extent to which laudanum may sometimes be given is well shewn in one of the cases of hysteria, which is probably as extraordinary as any on record; and in one of mania. Iodide of potassium seems well adapted to these affections; my experience of it, however, has not been sufficient to establish its utility. The efficacy of turpentine, arsenic, copper, iron, zinc, and nitrate of silver, and creasote? is too well known to require a remark; the nitrate, in my experience, has done most good when it has acted as a purgative. Electricity, in one of the cases of chorea, was of decisive benefit.

The incision of the scalp mentioned above requires an additional remark. It has been recommended by Dr. Abercrombie, and subsequently by Dr. Pritchard and others, as a step to making an issue. I am convinced, however, from its instant good effect in four cases in which I have tried it, that the benefit is in a great degree owing to the bleeding of the vessels of the part which is the seat of pain, and of an important source of irritation, and also to the relief of the tension of the scalp and the pericranium.

In all cases of spasms, with headache or lethargy, I would examine the whole of the skull by percussion; and wherever tenderness should be evinced, I would deeply scarify the part. Suppuration might also be established, by inserting lint soaked in oil of turpentine into the wound.

[To be continued.]

PERICARDITIS AFTER SCARLET-FEVER.

To the Editor of the Medical Gazette.

SIR,

DR. SOMERVILLE SCOTT ALISON, in his article on the above subject, has alluded to several authors who have not, and to some who have, treated of the disease. I wish you to allow me the favour of stating, that I drew particular

attention to this subject in a paper on Dropsy after Scarlet-Fever, which I read to the Westminster Medical Society on Dec. 7, 1839. An abstract of the paper appeared in the report of the Society in the *Lancet*, seven days later. I related thirteen cases in detail to the Society, and out of these there was well-marked pericarditis in three cases, and extensive hydrops pericardii, probably unconnected with local inflammation, in two others.

I am not surprised that Dr. Alison is unacquainted with my paper, and I chiefly write to express my dissent from his opinion that pericarditis occurs at an early period in scarlet-fever. I consider that it arises only as a consequence of the renal disease which is apt to follow scarlet-fever. I admit that the kidney is generally disordered during the first few days of the fever, and that its functions are disordered during the rheumatic swellings of the joints which sometimes accompany the eruption, or appear very soon after it; but I am of opinion that pericarditis only comes on as a consequence of that congestive disease of the kidneys in which they fail duly to separate the urea from the blood, which disease is never established till a fortnight, and generally not till about three weeks, from the commencement of the fever. Dr. Alison remarks that pericarditis is liable to follow obstructive disease of the kidneys. I have seen it do so independently of scarlet-fever: it occurred only in this manner in the cases related in my paper. I have taken notes of a great number of cases of scarlet-fever, both with and without renal sequelæ, since reading the paper in 1839; these cases tend to confirm the opinion I have expressed respecting pericarditis, and I see nothing in the three cases related by Dr. Alison to induce me to modify that opinion. The subject of the first case was not seen till near death, between two and three months after the fever; in the second case the disease certainly commenced early, but the child, on a previous occasion, had had an attack of an inflammatory nature in the left hypochondrium, and Dr. Taylor discovered hypertrophy of the heart only forty-four days after the fever commenced: I therefore conclude that there was disease of the heart in a chronic form, which was rendered acute by the scarlet-fever, as

it might have been by any thing which would excite the circulation; and so I am inclined to look on this case as an exception, tending to prove the rule I have expressed. The subject of the remaining case was not seen by Dr. A. till nine weeks after the scarlet-fever, and there is no account by any medical man of the previous illness.

There are many valuable remarks in Dr. Alison's article, and I shall look forward with interest to his promised cases of anasarca following scarlatina.

I am, sir,

Your obedient servant,

JOHN SNOW, M.D.

Frith Street, Soho Square,
Feb. 25, 1845.

CASE OF
ENCEPHALOID DISEASE OF THE
TIBIA AND SOFT PARTS.

By EDWIN HALL, M.D.*

MAY 3, 1842, was called to see Thomas, son of James H—, aged 15. He was tall, of spare habit, with dark hair and eyes, and a very fair and light complexion. Though delicate in appearance, I learned that previous to this attack he had enjoyed good health. He complained of an intense and deep-seated pain in his right leg, which was not confined to one spot, but extended from the tubercle, giving attachment to the ligamentum patellæ, half way down the shaft of that bone. The patient located the pain in the bone—said "it was sometimes on the front, sometimes on the back side of it." The limb, though slightly swelled, had a natural look and feel, and was not tender to the touch, except in one spot, of the bigness of a lime, just below the attachment of the ligamentum patellæ. No cause could be assigned for the origin of the disease farther than this, viz., the patient thought he hurt his leg sliding down hill the previous winter, and it had pained him occasionally since that time. A small opening had been made into the limb by the physician who attended him prior to my being called; but for what purpose I know not, as there was no evidence of a collection of matter or other fluid. The wound, though open, was free from discharge. As regards the general condition of the patient,

* Amer. Journ. of the Med. Sciences, Jan. 1845.

his bowels were regular, tongue clean, appetite good, and pulse but little accelerated. Not being able to determine the nature of the disease, my prescriptions were such as the symptoms indicated.

In the course of two or three weeks, it became evident that the disease was rapidly increasing, but whether it would prove to be malignant was a question as yet not easy to be determined. The limb had been gradually increasing in size, and was now somewhat discoloured. Feeling, as I supposed, a fluctuation on the anterior and external face of the limb, I made an incision into it. Nothing but a thin sanious matter was discharged, indicative of disease of the bone. A probe readily passed so far into the wound as to be felt on the opposite side of the limb. A considerable flow of blood followed the withdrawal of the probe. A few days after I made the opening, it was observed that the limb was increasing in size with more rapidity than it heretofore had done; that the edges of the wound had begun to evert and put on a fungous appearance. As soon as I observed this fungus, I apprised the parents of the malignancy of the disease, and advised amputation. But hoping against hope, they wished to defer it for a few days.

The only relief which the patient could get from the intense pain he has suffered since the commencement of the disease, was in large and often-repeated doses of morphia, and poultices made of the fresh juice of *conium maculatum*.

June 4th.—Dr. Hubbard, of Halliwell, being in town, was called in, and advised immediate amputation.

Condition of the patient at this time.

—Much emaciated; pulse 130; glands in the groin not enlarged; limb below the knee exceedingly enlarged, very elastic when percussed, and of a purple tinge. A fungus of the size of a hen's egg protrudes from the wound made a week or more before. The lymphatics running over the diseased portion, resembled in size small varicose veins, and were filled with an amber-coloured fluid.

5th.—Assisted by Drs. Tewksbury and Palmer, I amputated the thigh at its middle. The patient bore the operation remarkably well. Very little blood was lost.

After dressing the stump, we turned

our attention to the examination of the limb. On cutting into it, a large quantity of dark fluid matter escaped, in which were irregular masses of what appeared to be muscular substance in a state of disorganization. In fact, the soft parts were so entirely disorganized, for the space of six or eight inches from the attachment of the ligamentum patellæ downward, that neither muscular substance nor blood-vessels could be recognised. Removing the fluid matters above mentioned, we found deposited on the posterior face of the bone, for the space of four inches below its head, a whitish substance, without organization, and bloodless. In some places this substance was of the colour, and as soft, as the cortical substance of a recent brain. In other places it was quite firm and hard, but without that elasticity and grating, when cut, peculiar to scirrhus. Patches of this were observable on other portions of the shaft of the bone, within the confines of the disease. On the anterior and antero-external face of the bone, commencing an inch below its articular surfaces and extending down two and a half inches, we observed alterations in texture worthy of notice. A little external to the crest of the tibia was a fissure from an eighth to a quarter of an inch broad, which extended horizontally through the bone. The texture of the external lamellæ of the bone, for a considerable space about this fissure, was entirely and uniformly destroyed. It resembled a carious bone, and was quite dark-coloured. To a considerable extent around this fissure, as it traversed the bone internally, were the same alterations in texture which we have noticed externally. The specimen is in my possession.

The patient made a rapid recovery, and the stump healed kindly. During the summer he was as active as usual, and gained flesh. Still his countenance was pale and his pulse quick. Various alterative remedies were prescribed, but he received no benefit from them.

Was again called to see him, Feb. 6, 1843. He complained of pain in his right side, in the region of the liver. Bowels costive; tongue coated; pulse 130; skin dry.

Cal. and rhubarb.

7th.—Cathartic operated; no better.

Blister to the side.

8th.—More comfortable, but still complains of pain in his side.

On stripping him and measuring from the xiphoid cartilage to the dorsal vertebrae, I found the right side to be three inches larger than the left. There was a lateral curvature of the vertebral column to the left, of an inch, commencing at the fourth dorsal and terminating at the lumbar. Dull sound on percussion over the whole of the right side of the chest. Respiratory murmur inaudible. This condition of things convinced me that his former disease had re-appeared, and consequently that his case was hopeless.

10th.—Right side, measured as before, is four inches larger than the left. Dyspnœa great; some cough; expectorates; appetite good.

Ipecac. and morphia.

12th.—Cough and expectoration have ceased, but the dyspnœa remains. Cannot lie in the horizontal posture. Has some difficulty in swallowing his food, which I attribute to the pressure of this immense tumor on the œsophagus.

23d.—Patient has been getting gradually worse since last report; is now very feeble. Dyspnœa excessive. Superficial veins on the right side of the thorax enlarged. Expired suddenly in the evening.

Autopsy, twenty-three hours after death.—Assisted by Dr. M. Call, we commenced the examination by opening the abdomen. The liver lay almost wholly on the left side of the median line, as also the gall-bladder. The stomach was quite small; its pyloric orifice lay almost directly below the cardiac. The transverse and descending colon was contracted to less than half its usual size, and was very light-coloured. The other organs normal.

Thorax.—The pericardium contained four ounces of serum. The heart was healthy, but forced out of its position to the left. Removing the heart, we found the left lung so much compressed by the right, that it appeared mysterious to us how it could have performed its functions so as to have sustained life for the last three or four weeks of the patient's existence. In its substance were two tumors, one of the size of a

hen's egg, the other of the size of a walnut, and resembling, more than any thing else, coarse grained loaf sugar moistened with water. They appeared quite different from any thing observed in the other lung. No tubercles were observed in this lung. The right lung was one mass of disease. It extended down to within two inches of the right iliac crest, and filled nearly three-fourths of the whole cavity of the thorax. It was firmly adherent to the costal pleura, and resembled a lung only in shape. The division into lobes could not be traced. In the apex was a cavity containing about 8 oz. of a dark turbid fluid, little thicker than serum; cutting into the lung, the outside to the depth of an inch, more or less, was generally very light-coloured, resembling the medullary substance of the brain. The central portion was rather dark-coloured, as if stained with blood, and fibrous when torn. No blood-vessels or bronchial tubes could be found. Some parts of this mass were soft, others hard and cartilaginous. The soft parts, which were always white, when cut presented a mammillated appearance, as if the morbid matter was deposited in dilated air-cells. There was no unnatural smell about it; neither was there about the leg, which this lung precisely resembled. This morbid mass, when removed and freed from fluids and other foreign matters, weighed ten and a quarter pounds.

CASE OF

ŒDEMA OF THE GLOTTIS.

By HENRY STANHOPE ILLINGWORTH.

(For the Medical Gazette.)

JAN. 18th, 1845.—I was sent for at half-past nine in the evening, to see A. B., who was in a state of approaching suffocation.

At 1 P.M. whilst eating a hot potato, a piece stuck in the throat, which after remaining there two minutes, according to his account, but, in all probability, for a much shorter time, he was enabled to swallow; it did not produce the sensation of scalding during its arrest.

Until 5 P.M. no inconvenience was experienced; he then felt his throat "rather sore," with slight oppression in "drawing in his breath;" this increased, and at 8 o'clock he became very uneasy, and, unknown to any one,

went to bed : about 9, a fellow-servant, in passing his room, hearing some one groaning, opened the door, and found him so ill, that I was immediately sent for.

On my arrival he was propped up in bed, partly supported and partly resting on his outstretched hands; his countenance was anxious and livid; his eyes suffused; his pulse very small, quick, and irregular, with inability to speak or swallow; inspiration, which was performed with a loud hoarse wheeze or stertor at long intervals, was followed by expiration attended with a suffocative effort to cough: having struggled with this for some seconds, a little glairy viscid mucus was got rid of, and renewed attempts at inspiration, more distressing than the former, took place.

Twelve leeches were applied to the throat, and ten grains of calomel smeared on the tongue. He was partially relieved before the leeches (which bled very freely) came off, breathing with less difficulty, and was able by a strong effort at swallowing to clear the calomel from the tongue; he also intimated, in a low whisper, that he was "better." On examining the fauces only a slight blush was perceptible on the velum palati, and a little fulness of the right tonsil.

A bladder of pounded ice was secured round the throat. Until nearly eleven, he continued to improve, the face partly assuming its natural appearance, and the pulse becoming fuller and slower: he was able to swallow a few teaspoonfuls of liquid. At this time a violent fit of coughing ensued, which fatigued him very much, and the symptoms became nearly as alarming as when I was first called to him. Mr. Moore now saw him, and as we feared bronchotomy might be momentarily required from an attack of spasm occurring, Mr. Cæsar Hawkins was called in a little before twelve o'clock. It was agreed to bleed him, and on twelve ounces of blood being taken from a large orifice, fainting supervened, on recovering from which he was able to express himself relieved, and could lie down; five grains of calomel were given, and an attendant who remained with him all night was to administer part of a mixture of sulphate of magnesia and mint water, according to his power of deglutition.

19th, 8 A.M.—He had passed a restless night, and as he had not been able to take much of the medicine, the bowels had not acted; respiration was still performed with considerable embarrassment. In consultation at ten o'clock, ten leeches were prescribed, and the bleeding to be encouraged by a bread-and-water poultice.

Haut. Salin. c. Liq. Antim. Tart. et Magnes. Sulph. quartis horis sumend.

2 P.M.—Much better.

10 P.M.—Very much improved, bowels much relaxed.

20th.—Going on well; after this nothing unusual occurred, and in an ordinary period he was cured.

I have a three-fold object in drawing attention to this case. Firstly: had it not been for the fortunate circumstance of some one passing his room, he might have remained undiscovered for some hours, when, most likely, he would have been found dead. "Instances have come to our knowledge," Dr. Cheyne writes, in speaking of laryngitis, "in which the disease has terminated fatally within twelve hours, (one of Dr. Armstrong's patients died in eight hours, and another in seven;) and, therefore, if a person dies suddenly in the night, who had complained on the foregoing day of sore throat, laryngitis may be suspected as the cause of his death."* There was no sore-throat complained of on the preceding day, no one being aware that he was ill; we should consequently have had not a little difficulty in accounting for the cause of death, as there was not even this symptom to guide us in our inquiries.

Secondly: the period of the super-vention of the symptoms is curious: four hours previously to their commencement a hot potatoe had been fixed in the throat, without any pain, or dyspnoea, arising for this length of time. In four cases of swallowing boiling water, related by Dr. Marshall Hall, which are in some respects analogous to this, difficulty of breathing appears to have begun directly after the accident.†

Thirdly: the marked mitigation of

* Cyclop. Pract. Med. vol. iii. p. 19.

† Underwood on the Diseases of Children, 9th edit. p. 364.

the symptoms from the treatment first adopted, shown in the improvement of the breathing and loss of lividity, and their return after a period of some duration, is worthy of recollection.

1, Arlington Street,
Feb. 17, 1845.

BAKER VERSUS LOWE.

To the Editor of the Medical Gazette.

SIR,

YOUR readers are already acquainted with the particulars of the action raised by Mr. Baker, of Hampton, against Captain Lowe for the recovery of his just dues, which was decided in favour of Mr. Baker in the Court of Queen's Bench on Saturday, the 15th inst. Though much indisposed to comment on the conduct of professional men, the circumstances of this case are such as to have roused my indignation.—It does, indeed, seem monstrous, that there should be found any member of the medical profession ready to come forward, with the will and purpose, and for hire, to put a fellow-practitioner in the wrong!

Captain Lowe's disease was spontaneous or senile gangrene of the great toe; and Mr. Baker treated his patient on the stimulating plan: the disease spread, and the Captain finally lost his foot, which was taken off by Mr. Liston. I am old enough to remember when the principle in surgery, in regard to senile gangrene, was—warm turpentine dressings to the part affected, and porter, and wine, and nourishing food, with the free use of opium internally. Of late years another view has been taken of the matter, and patients affected with senile gangrene have had poultices and soothing topical applications, together with a restricted regimen and anodynes, prescribed for them. The old plan of treatment was not always unsuccessful, any more than is the later mode of procedure constantly successful, in arresting the disease. I have seen spontaneous gangrene cease to make progress under beef-steaks and London porter to the stomach, and hot spirits of turpentine to the mortified toe; and I have known the disease continue its destructive course under the most soothing local applications, and chicken-

broth and panada as aliment; and I will venture to say, so have Mr. Lawrence, and Mr. Key, and Mr. Skey. Nevertheless, these gentlemen all gave their evidence in such a way as to lead to the conclusion, that had Mr. Baker followed another plan of treatment—the plan which they approved—Captain Lowe would not have lost his foot. They ought rather, in my opinion, as being familiar with the dangerous and generally uncontrollable character of senile gangrene, to have been found ready to throw the weight of their name and authority into Mr. Baker's scale: instead of making themselves partizans in the case, and doing all in their power to crush him, their true and proper place was certainly by his side, and upholding him. These gentlemen ought, in fact, to have seen this Captain Lowe as a shabby fellow—one who was but too ready to receive Mr. Baker's care and attentions whilst they could be of use to him, without a word about want of skill; it was only when the question came to be of payment, of rewarding Mr. Baker for his visits innumerable, and his attentions without end, that Captain Lowe started the objection of want of skill on the part of his kind attendant, and cruelly and recklessly refused to pay, on grounds that were calculated to ruin in public estimation the man who had been so unwearied in his attendance on him. That the whole affair hung on the *indisposition to pay* was made abundantly manifest by the treatment which Mr. Liston received; inasmuch as that gentleman received merely half his fee,—thirty, instead of sixty guineas, for some four or five visits as far as Hampton. Captain Lowe could not urge want of skill against Mr. Liston, but pleaded poverty, and tendered him but half his fair recompense. Yet it came out in the evidence that this Captain Lowe was living in retirement, not only knowing nothing of the *res angustæ domi*, but actually in circumstances which permitted him to keep a hunting stud for his son! The son of this captain, who, it might be fairly said, kept back from one of his surgeons half his fee, and attempted to trick the other, ruining his character as a professional man at the same time—the son of this man hunted twice or thrice a week!

Had Mr. Baker been unquestionably

mistaken in his practice, (and there is not the slightest reason to suspect that the result would have been other than it was, had different measures been taken from the first) I still maintain that it was neither fair nor seemly in any of his professional brethren to come forward against him: there was no principle of public justice involved in Mr. Baker's procedure. Had Captain Lowe died of senile gangrene, as he happily recovered, is it not notorious that the disease is little under the control of treatment of any kind? Let us see what Mr. Lawrence himself says on the subject: "Very commonly," says that gentleman, "from the part at which it begins, it extends further; so that generally, when you see an occurrence of the kind, you will find that the patient will die from it, although the mortification in the first instance should appear very slight."* But, supposing Mr. Baker to have been palpably wrong, we ask—Do mistakes never occur in the practice of hospital surgeons? have not tumors sprouting from bones been mistaken for aneurisms, and such counsel given as led to the ligation of large vessels, with no less a consequence than loss of life to the patient? Has not a trifling degree of wry-neck, dependent on original conformation of the skeleton, been mistaken for wry-neck induced by contraction of the muscles of the neck, and perseverance in subcutaneous sections in such a case been followed by inflammation and fever, and death; so that the young woman who had left her home one week full of life and hope, was carried back the next, a senseless corpse in her coffin? Shame! shame upon us! that we should be found ready at the bidding of any scurvy wretch who would keep the money in his pocket, to attempt to prove one another in the wrong!

I remain, sir,

A CONSTANT READER.

Feb. 28, 1845.

BOARDS OF GUARDIANS AND DISTRICT MEDICAL OFFICERS.

To the Editor of the Medical Gazette.

SIR,

THE following cases (with others) have lately been the subjects of public

* Lectures in *Lancet*, 1829-30, vol. i. p. 425 et seq.

investigation before the Board of Guardians relative to the neglect of the district medical officers, in which I was summoned as the medical evidence. My treatment having been very extensively and illiberally canvassed, in addition to personal insult, I shall be particularly obliged by your inserting the subjoined in your valuable periodical as early as convenient.

Jan. 15, 1845.—About 8 o'clock in the evening, I (as the nearest surgeon) was called to the wife of David Fleming, labourer, of Rond. Upon my arrival I found the woman (as stated in my evidence) "all but dead," lying upon her back: blanched countenance, cold extremities, pulseless at wrist, the heart acting very feebly, &c, the effects of severe uterine hæmorrhage attendant upon an abortion between the third and fourth month (near the latter). Upon examination, I found the fœtus had escaped, the placenta partially detached, the remainder morbidly adherent, no uterine action, hæmorrhage still continuing. I gave a draught of Ammon. c. Pulv. Secale Cornut., ordered warmth to the extremities, from time to time supported her with brandy and water, and proceeded to extract the placenta by holding the fundus uteri with my left hand just over the pubis, for the double purpose of steadiness and pressure, and, with the fore-finger of my right, endeavoured to detach the placenta, which, with the aid of my middle finger, I, with much difficulty, ultimately did, *in several pieces*, many not larger than the top of my finger. I then applied pressure by a compress and bandage, put her into bed, continued the warmth and stimulus, waited a long time, gave an opiate, and, when I could safely do so, left her. I have fortunately since had the after-treatment of the case, which consisted in supporting her by wine and nourishment, and giving her Tinct. Opii c. Tinct. Ferri Hydrochlor. and attending to the secretions, under which the woman has progressed favourably, though still suffering from debility.

In this case, during the investigation I was personally, and, I contend, most unjustifiably, insulted by the district medical officers (Messrs. ———), declaring that "they did not believe that the woman had miscarried at all" (although other evidence than mine fully proved that fact), and inquired of

me "whether I had ever before attended an abortion?" This will doubtless meet the eyes of many of my hospital friends, who, during my sojourn among them, designated me "the midwifery man;" and I have the *decus et tutamen* of holding the honorary certificate of my justly-respected, and highly esteemed friend and instructor, Dr. F. H. Ramsbotham, for "the great number of cases of difficulty and danger I attended whilst one of the accoucheurs attached to the Tower Hamlets Dispensary as a medical student at the London Hospital"; my brother students, when any such occurred, kindly sending for me to assist. I would not, however, for an instant let it be thought that I am presumptuous enough to arrogate to myself a greater amount of obstetric knowledge than ought to be possessed by every practitioner. Again, it was urged "that I ought to have waited; had I done so, the placenta would have been spontaneously expelled:" or else "I ought to have used the plug"—that being the practice they (the medical officers) would have adopted. To which I replied, "then you would have killed the woman;" as, first, far too much time had elapsed prior to assistance being procured; and the placenta itself, or rather a large portion of it, was so very "morbidly adherent"—a term much cavilled at, but which I submit is correct—that there was very little probability, if any, of its being spontaneously expelled; there being no uterine action, and the extent and strength of the adhesion being, I contend, proved by the extraction in many small pieces; as I much question the possibility of any man being able to do in the absence of all uterine contraction, irregular or otherwise, unless the placenta be morbidly adherent. And secondly, relative to the use of the tampon: having seen it adopted in several cases, in some, I think, with absolute disadvantage, the women, in three or four instances, having gone into a state of collapse from internal hæmorrhage, though not a drop flowed externally. I therefore by no means should have felt myself justified in exposing my patient to a risk which, had it occurred, must have proved fatal to her under the before-detailed extreme circumstances.

The second case is that of Benjamin Cheverton, labourer, of Rond, to whom I was called March 12th, 1844, a gravel-pit having foundered upon him, whereby he sustained dislocation of the ankle-joint, with fracture (as usual) of the malleolus internus. I reduced the dislocation, and replaced the fractured portion of bone, then placed the limb on the outside (thigh and leg flexed) with a splint, upon a pillow: my object in placing the limb in the flexed position was the relaxation of all the muscles, and more particularly the flexor longus, digitalis perforans, and tibialis posticus, the tendons of which muscles, as every surgeon knows, pass round the inner ankle, which in this case was completely fractured off. I attended the case a day or two, when one of the district medical officers (not a surgeon), Mr. H—T— took charge of the case. He then made some very unjust and illiberal observations as to my incompetency to reduce a dislocation, or set a fracture, said that my treatment was all wrong, and placed the limb in the extended position, upon Macintyre's apparatus, which he fastened to the bedstead, tightly bandaging the limb upon it, in which position he kept it for three weeks of (in my opinion) invaluable time, as regarded the integrity of the joint, during which time, upon each removal of the bandage, the fractured malleolus was always found considerably displaced. At the expiration of this period, the precise position and treatment which I in the first instance had recourse to was re-adopted; the poor fellow suffering for a long time from extensive sloughing of the sole of the foot, the probable cause of which it is not for me to say—whether the tight bandaging might have given rise to it "is a matter altogether of opinion." Suffice it to say, that in the after treatment no strapping (and but a modification of a bandage), nor passive motion, &c. was employed, and now the man has ankylosis of the ankle-joint, with considerable displacement of the malleol. intern.; in short, he is a cripple for life.

I really fear, Mr. Editor, that I have too much trespassed upon your valuable space. I have been as brief as possible, consistent with accurate detail, but as the affair does not alone involve my personal interest, (as also from its having

been publicly investigated) I trust you will excuse the length, and give it early insertion.

I have the honour to be, sir,

Respectfully yours,

J. J. E. PORTER, Surgeon, &c.

Godshall, Isle of Wight,
Feb. 28, 1845.

ANALYSES AND NOTICES OF BOOKS.

“L’auteur se tue à allonger ce que le lecteur se tue à abrégé.”—D’ALEMBERT.

Anatomical and Pathological Observations. By JOHN GOODSIR, F.R.S.E., Demonstrator of Anatomy in the University of Edinburgh, and HARRY D. S. GOODSIR, M.W.S., Conservator of the Museum of the Royal College of Surgeons. Edinburgh: Myles Macphail. London: Simpkin, Marshall, and Co.

THE College of Surgeons of Edinburgh are fortunate in having secured the services of two such able observers in physiology and pathology, as the Messrs. Goodsir.

The present work comprises the following subjects:—centres of nutrition;—the structure and functions of the intestinal villi;—absorption, ulceration, and the structures engaged in these processes; the process of ulceration in articular cartilage; secreting structures; serous membranes; structure of lymphatic glands; structure of the human placenta; structure and economy of bone; besides some anatomical, zoological, and pathological observations, confirmatory of the centres of nutrition and of secretion.

By centres of nutrition are understood certain minute cellular parts existing in the textures and organs. They are, accordingly, of two kinds: those which are peculiar to the textures, and those which belong to the organs. Those of the former are generally permanent, while those in the latter are, in most instances, peculiar to their embryonic stage, and, either disappear, or break up into the various centres of the textures of which the organs are composed:—

“A nutritive centre, anatomically considered, is merely a cell, the nucleus of which is the permanent source of successive broods of young cells, which from time to time fill the cavity of their

parent, and carrying with them the cell-wall of the parent, pass off in certain directions, and under various forms, according to the texture or organ of which their parent forms a part.

“There is one form in which nutritive centres are arranged, both in healthy and morbid parts, which is frequently alluded to in the following chapters, and which may be named a germinal membrane. In a germinal membrane, the nutritive or germinal centres are arranged at equal or variable distances, and in certain directions, in the substance of a fine transparent membrane. A germinal membrane is occasionally found to break up into portions of equal size, each of which contains one of the germinal centres. From this it is perceived, that a germinal membrane consists of cells, with their cavities flattened, so that their walls form the membrane, by cohering at their edges, and their nuclei remain in its substance as the germinal centres.

“Germinal membranes are only met with on the free surfaces of parts or organs. One surface of the membrane is therefore attached, and is applied upon a layer of areolar texture, intermixed with a more or less rich network of capillary vessels. The other surface is free, and it is on it only that the developed or secondary cells of its germinal spots are attached. These secondary cells are at first contained between the two layers of the membrane, these layers being the opposite walls of each of its component cells. When fully developed, the secondary cells carry forward the anterior layer, which is always the thinnest, leaving the nuclei or germinal centres in the substance of the posterior layer, in close contact with the blood-vessels.”

In describing the intestinal villi, some very clear and interesting observations are made in regard to digestion: Mr. J. Goodsir is led to believe that absorption by growth and solution is the process which actually takes place. Hence “the vesicular extremity, like the spongiole of the root fibril, is the primitive nutritive centre of the villus. The villus originates in a cell. During the development of the villus, this spot or cell was employed only in procuring materials for the growth of the organ. In the perfect animal the formative function of the spot ceases; its action becomes periodical, active during di-

gestion, at rest during the intervals of that process. The same function is performed, the same force is in action, and the same organ, the cell, is provided for absorption of alimentary matters in the embryo and in the adult, in the plant and in the animal. The spongioles of the root, the vesicles of the villus, the last layer of cells on the internal membrane of the included yolk, or the cells which cover the vasa lutea of the dependent yolk, and the cells which cover the tufts of the placenta, are the parts of the organism in which the alimentary matters first form a part of that organism, and undergo the first steps of the organizing process."

The following are his views with reference to ulceration:—

"A rapidly extending ulcerated surface appears as if the textures were scooped out by a sharp instrument. The textures are separated from the external medium by a thin film. This film is cellular in its constitution, and so far it is analogous to the epidermis or epithelium. It is a peculiarly endowed cellular layer, which takes up progressively the place of the subjacent textures, these being prepared for dissolution, either by the state of the system, the condition of the part, or by some influence induced by the contiguity of the new formation. Carrying out, therefore, the principles at present regarded as regulating the reciprocal functions of textures and vessels, the subjacent textures disappear in consequence of a disturbance of their own forces, consequent upon the appearance of new forces residing in the cellular layer. The disturbance and gradual annihilation of the natural forces residing in the subjacent textures is indicated by the gradual disappearance of these. That new forces, not formerly existing in the part, are developed, appears from the formation of the cells of the cellular layer. As these appear in rapid succession, and disappear as rapidly, the subjacent textures also disappear, either by previous solution and subsequent absorption by the properties and powers of the former; or under the peculiar circumstances of inflammatory action by the more vigorous growth of the former, monopolizing the resources of the part, the latter dissolving and disappearing by the usual channels of the returning

circulation, more rapidly, but according to ordinary laws."

At page 83 a curious mistake is pointed out into which Mr. Erasmus Wilson has fallen as regards the *echinococcus hominis*. There can be no doubt, according to our authors, that the *echinococcus* described by Mr. Wilson in a paper read before the Royal Medical and Chirurgical Society, and of which an abstract was published in the *MEDICAL GAZETTE* for 1844, is of one and the same species with the *Acephalocystis armatus*. The bodies defined as the echinococci, and which are attached to the internal surface of the membrane, are merely the young acephalocysts either of the secondary or tertiary stages of development; secondary, if found growing from the walls of the original containing sac. The animal is therefore an acephalocyst, and not an echinococcus.

A spirit of minute and accurate research characterises the whole series of observations.

Elements of Physics. By C. F. PESCHEL, Principal of the Royal Military College at Dresden, and translated from the German, with Notes, by E. WEST. Illustrated with diagrams and woodcuts. Part I. *Ponderable Bodies*. 12mo. pp. 307.

A CENTURY and a half has elapsed since Natural Philosophy, in its extended sense, as the study of the mechanical phenomena of the universe, was deemed an indispensable attainment by the medical man, who originally obtained the title physician, from his acquaintance with the principles of physics.

About the above period, the mathematical sect, which had originated with Borelli, was illustrated by Harvey, and systematized by Bellini, expired with Pitcairn, Mead, and Friend. Borelli's explanation of the muscular movements, a series of mathematical propositions, is replete with scientific truth, and may be studied by the anatomical physiologist at the present day with advantage. Though this mechanical school of medicine has been long justly exploded, it is notwithstanding incumbent upon every student who is ambitious of becoming an accomplished physician to make himself familiar with the laws of nature that govern the material elements which exercise

incessant influences on the living frame. The little work of Peschel affords a convenient manual to medical men for learning the principles of this important preliminary science. The part now published, under the title *Ponderable Bodies*, treats of what other writers would style statics and dynamics. For instance, after an introductory section on the physical properties of bodies, physical forces in general, molecular attractions, and gravitation, he discusses, in section 2, the laws of motion in general, including gravity, descent on inclined planes, projectiles, motion round a centre, &c. In the 3d section, the doctrines of the pendulum, and the mechanical powers, are treated of, under the singular title of *Solid Bodies*. The sections on non-elastic and elastic fluids will probably be found to be the most interesting by the medical world. Vibrations and acoustics constitute the subjects of the 6th and 7th, or last, section.

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medice tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

It was proposed in the draught of the bill of last session to associate the Faculty of Physicians and Surgeons of Glasgow with the University of that city, in examining for the degrees of bachelor and doctor of medicine. The faculty was to be styled the Royal College of Physicians and Surgeons of Glasgow. The proposition was made in the belief that the said faculty had in the four adjacent counties power to license practitioners in medicine as well as in surgery, which is not the fact. Sir James Graham therefore thinks it on the whole better to withdraw that provision, and to give the sole power of licensing, so far as Scotland is con-

cerned, to the Colleges of Physicians and Surgeons in Edinburgh.

The right and privilege of examining and licensing practitioners in surgery and pharmacy, was conferred upon the faculty by Royal Charter upwards of two hundred years ago, secured to them afterwards by acts of the Scottish Parliament, and very recently by decisions of the House of Lords.

We believe that no just complaint has ever been urged of their having exercised in an improper manner the power thus granted to them. On the contrary, their constant aim has been to benefit the public, and to raise the status and character of the medical profession to the utmost of their ability. The curriculum of study, they maintain,* has always been as full and complete, and the examinations as strict, as those of any other licensing body in the kingdom. This ancient and respectable corporation, we may add, possesses a spacious hall, a valuable and extensive library, and a well endowed fund for the support of the widows and orphans of its members.

We therefore regard the intended withdrawal of its privilege as a serious hardship, fraught with most hazardous consequences to the medical school of Glasgow, inasmuch as it may be naturally supposed that students will hereafter resort chiefly to those places for medical education where they can likewise obtain the license to practise.

We are, moreover, disposed to doubt whether the contemplated act, originating, it is said, in Irish jealousy, be not in some respect an infringement of the Treaty of Union between the two kingdoms. It is there stated that no alteration should be made in laws which concerned private right, except for evident utility of the subjects within Scotland. Now it is undeniable that the peculiar privilege in question

* Memorial of December, 1844.

was held by the Faculty of Physicians and Surgeons long anterior to the year 1707, the date of the Union; and we would humbly suggest whether its abrogation be not more likely to prove a source of detriment than advantage to one of the most important cities of the empire. Glasgow has a population of 300,000, which is rapidly increasing. It is the seat of a famous university, and of a long-established school of medicine. It has a general hospital, containing nearly 500 beds, in which, during the last fourteen years, 3,500 patients have been treated annually, and where, for a considerable time past, clinical instructions in medicine and surgery have been regularly given to a large concourse of students. There are other smaller hospitals, and numerous dispensaries for the cure of the sick and diseased poor. Glasgow has an extensive and flourishing sea-port, and being situate in the centre of mining, manufacturing, and mechanical works of great magnitude and variety, serious accidents are daily occurring which call for the most prompt and skilful appliances of surgery. Hence ample opportunities are afforded the student of acquiring a thorough and practical knowledge of his profession.

On the grounds, therefore, of long undisturbed tenure on the one hand, and of probable detriment to the community on the other, do we argue against the proposed withdrawal of their license from the Faculty of Physicians and Surgeons of Glasgow.

To the objection that this faculty is an anomalous body, composed of the two classes united, we attach no weight.

If it has been deemed expedient to make a special provision in favour of Oxford and Cambridge, "those twins of learning," where medicine heretofore has been confessedly taught in a very loose and incomplete manner, why not

do something of the same kind for Glasgow? Might not an assessor be sent thither at stated periods from the College of Surgeons of Edinburgh, invested with the power of licensing practitioners in medicine and surgery, conjointly with the examiners of the above faculty, since it is only in so far as general practitioners are concerned that their authority extends? In this point of view, the circumstance of their being a mixed constituency, made up of physicians and surgeons, should rather operate beneficially than otherwise. The necessary elements already exist for furnishing a suitable board to examine and license the candidate in physic and surgery. Of course it would be incumbent on the assessor to see that the curriculum, and other requisitions enjoined by the Council of Health, were rigorously observed.

From the contemplated changes we anticipate nothing short of a rapid and irremediable decline of the medical school of Glasgow. The regius professor of surgery is, we perceive, to be a member of the Council of Health. Should our gloomy forebodings be realized, he will, no doubt, find ample time for fulfilling in person the duties of his metropolitan appointment.

This, however, is no light matter. On the contrary, it is one entitled to the deepest thought. We therefore trust that the legislature, before taking any decided step, will weigh well the probable consequences which may result from annihilating the existence of so useful a body as the Faculty of Physicians and Surgeons of Glasgow. The spirit of common justice opposes its being thus immolated, while other institutions, more influential it is true, though not a whit more deserving of consideration, are still to be upheld in their special rights and immunities.

HINTS TO MEDICAL JOURNALISTS.

LONDON has three weekly medical journals, conducted with great ability, viz: "*The London Medical Gazette*," "*the London Lancet*," and the "*London Times*." Of these, the two latter occupy antagonist positions, and may be said to represent opposite parties or factions of the profession in that metropolis. Accordingly, we find, mixed up with much valuable matter, a large amount of a different stamp—very interesting, no doubt, to the physicians and surgeons of London, but about as much so to us in the United States, as our Corporation, County and State politics, are to our brethren on the other side of the Atlantic. The discussions on "Sir James Graham's Bill," "Medical Reform," the fitness or unfitness of the last appointment at St. Bartholomew's, St. Thomas's, at Guy's, "Movement of the Profession," "Great meeting at Leeds," "at Manchester," &c. &c., with many other things proper to London, are all very well in their place, but to American physicians they are nearly as cabalistic as "the secret science of the Jews."—*Philadelphia Examiner*.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Tuesday, February 25th, 1845.

MR. STANLEY, President, in the Chair.

On the Mortality in Prisons, and the Diseases most frequently fatal to Prisoners.

By WILLIAM BALY, M.D. Physician to Millbank Prison, and Lecturer on Forensic Medicine at St. Bartholomew's Hospital.

THIS paper, of which only an abstract was read, contains the results of an inquiry into the rate of mortality, and the nature of the more prevalent diseases in the Millbank Penitentiary, and other penal establishments, during the last fifteen or twenty years.

The annual rate of mortality in the different prisons of England, calculated from the average number of prisoners, and the number of deaths, exclusive of the deaths from Asiatic cholera, has ranged from 15½ per thousand to nearly 39 per thousand; in the state prisons, or penitentiaries, of the United States, from 19 to 39 per thousand; and in Switzerland from 25 to 35 per thousand. In France, the mortality, including deaths from Asiatic cholera, has ranged, in the hulks, from 39½ to 55½ per thousand,

and in the Maisons de Force et de Correction from 30½ to nearly 87 per thousand.

The annual rate of mortality amongst persons at liberty, in the different countries and cities in which these prisons are situated, and at the periods of life of prisoners, has varied very little from 15 per thousand.

The excess of mortality has been much greater in some prisons than in others; but the amount of this excess of mortality is no measure of the degree in which the health of the prisoners is affected by the discipline, diet, and general arrangements to which they are subjected, since there are many circumstances, independent of all systems of prison discipline and internal prison arrangements, which greatly affect the number of deaths occurring in prisons. The most important of these circumstances are, 1st, the extent to which the practice is carried of granting pardon to convicts in failing health; 2d, the degree of predisposition to disease of the class of persons forming the population of the prison; 3d, the length of confinement which the prisoners undergo; and 4th, their liability to endemic and epidemic diseases owing to the situation of the prison.

The high rate of mortality which prisoners suffer is really the effect of their punishment, and is not owing to the unhealthiness of the class whence criminals are, for the most part, derived. This is proved by the increased mortality which attends an increased duration of imprisonment, and by the result of comparing the rates of mortality in English prisons with the rates of mortality of the population of Liverpool, the most unhealthy town in England. The mortality of persons of the ages of 15 to 70, in Liverpool, during 1841, was 18 per thousand living. But the annual ratio of deaths amongst the prisoners in the county prisons of England has been nearly 23 per thousand; amongst those confined in the Millbank Penitentiary at all periods of imprisonment, nearly 31 per thousand; and amongst those passing through the third year of their confinement in that institution, more than 52 per thousand.

In America, France, and Switzerland, as well as in England, the proportion of deaths occurring annually has been much greater amongst criminals in prisons than amongst persons of a corresponding class of society out of prison.

The diseases to which this increased rate of mortality has been chiefly due in the Millbank Penitentiary, and all prisons where criminals are confined for long periods, are the various forms of tubercular scrofula, and especially tubercular phthisis. No other class of diseases has produced uniformly in all prisons a higher ratio of deaths, than the same class of diseases causes amongst persons at liberty; whilst the mortality from

many diseases is less in prisons than amongst the free population. Even where endemic diseases have been prevalent, owing to the unhealthy site of the prison, the great excess of mortality has still been caused by tubercular diseases.

The causes which have rendered tubercular disease so frequent and so fatal in prisons are, in the author's opinion—1st, deficient ventilation; 2d, cold; 3d, sedentary occupations, and want of active bodily exercise; 4th, a listless, if not dejected state of mind; and 5th, poorness of the diet.

The diet in the Millbank Penitentiary, and in the American prisons, has been more abundant than that of the agricultural labourer. But, in many other prisons, the allowance of food has been very scanty.

In respect of the diet, and also of the ventilation and warming, a great improvement has recently been made in the prisons of England, and it is to be expected that after the lapse of a few years a great amelioration will be found to have taken place in the health of prisoners.

Dr. Webster, without expressing his concurrence in all the opinions now promulgated, agreed with the author respecting the effects produced upon prisoners when only confined for a short period, who often left the prison in an improved state of health, compared with their previous condition. This fact had been generally observed in gaols, and he would, in confirmation of that opinion, refer to the results met with during the last two years at the City Bridewell, as he could speak on the subject from personal knowledge. The Fellows, of course, knew that the persons committed to this prison were dissolute and depraved characters, who had been exposed to the inclemencies of the weather, and often to the want of food; nevertheless, most of them leave the prison in better condition than at their committal. The period of confinement varies from a few days to three months, the average length being thirty days. To prove that the health of the City Bridewell prisoners is not deteriorated by their confinement, he (Dr. W.) would remark, that during 1843, when the committals were upwards of 1,000, only sixteen infirmary cases occurred, and one death; whilst in 1844, when the numbers committed amounted to nearly 1,150, there was only one death during the year, and twenty-four infirmary cases, most of them being trifling complaints. Properly speaking, even the single death recorded ought not to be ascribed to the prison discipline, since the patient remained fourteen days in Bridewell, and was an old vagrant, who laboured under fever at his committal, and had suffered much from misery and destitution. Long confinement often injures

the health of prisoners, but short periods frequently prove advantageous, as shewn by Dr. Baly's observations. He (Dr. W.) also agreed with the author as to the frequency of phthisis and bowel complaints; indeed, at the Penitentiary, consumption seemed lately to have been the most fatal disease amongst the inmates. The parliamentary report for 1844 stated that of the eleven deaths met with in that prison during the previous year, seven were from phthisis; at the same time, amongst the fourteen criminals pardoned on account of impaired bodily health, the majority were affected with pectoral disease, seven being phthisis, and one pleurisy. Again, in 1842, epidemic dysentery was very prevalent in the Penitentiary, when nine deaths occurred from that disease. He made these remarks on purpose to ascertain whether the author coincided with him that the mode of ventilating and warming prisons usually employed materially contributed to increase pectoral diseases amongst the inmates. The breathing of hot dry air irritates the mucous membrane of the lungs, produces cough, and, according to his (Dr. W.'s) opinion, in addition to the mental depression of prisoners, this dry and overheated atmosphere tended to bring on consumption, especially in those predisposed to that complaint. Besides local causes, the food consumed had, he thought, much influence on the production of bowel complaints, particularly the frequent use of liquid food, such as pea-soup; perhaps Dr. Baly would state his views to the Society on these points. Although the author, in the abstract of his paper, had only alluded to the bodily diseases affecting the Penitentiary inmates, there was another question of equal importance, to which he (Dr. W.) would wish to direct attention, in order to learn from Dr. Baly how far the mental condition of the criminals was affected by the discipline and seclusion of the prison, when they were placed in solitary confinement. This was an important subject, and one which had recently occupied the attention of philanthropists and medical men in this country, as also in France and America. Dr. Baly might feel unwilling to reply to such questions, as he held a public appointment under government; but he (Dr. W.) being differently situated, considered it would not be out of place to mention, in a medical society like the present, a few facts illustrative of the influence which solitary confinement produced, from the records of the prison to which Dr. Baly is attached. In 1839, according to parliamentary reports, three insane patients were sent from the Penitentiary to an asylum; five in 1840, or, taking the eighteen months prior to July, 1841, when the solitary system was strictly enforced, fifteen persons

became insane ; whereas, during the subsequent eighteen months—that is, when an important modification took place in the prison discipline—five insane criminals were removed, and only two during the year embraced in the report of 1844. This remarkable diminution in the number of Penitentiary inmates transferred to a lunatic asylum is conclusive on the subject, as it occurred subsequent to the period when the prohibition to intercourse was limited to three months after admission, the prisoners being then permitted to converse with two or three other prisoners during the hours of exercise, attention being, however, paid to the age, the disposition, and offences of the criminals thus allowed to associate together. Stronger evidence cannot be adduced respecting the effects which solitary confinement exerts upon the minds of ignorant or depraved individuals, than the facts just stated. He (Dr. W.) entertained strong opinions upon this question, and considered no punishment so severe to a living human being as long-continued seclusion from the company of his fellow creatures, especially to uneducated individuals, often devoid, not only of any good principles to fall back upon during their solitude, but who were, instead, frequently the slaves of their own evil passions.

Dr. Baly observed that his paper had reference simply to the effect of imprisonment on the body, and he therefore should refrain from answering Dr Webster's question in reference to the effect of solitary confinement on the mind. In regard to the influence of heated air in the production of phthisis, in the Penitentiary, cold appeared to have the most injurious influence on the prisoners. He could not trace the production of phthisis to hot air. Facts were, however, he believed, on record, to shew that hot air was injurious, although, as yet, he was aware of no information from any prison which warranted a belief that it caused phthisis. With respect to diarrhoea and dysentery, he felt convinced, when these diseases were prevalent for any lengthened period, that they were not produced by the kind of food which had been taken, but owed their origin to some peculiarity of the locality in which the prison was situated. Liquid and poor diet, though they would not originate, nevertheless aggravated these diseases. He had, in his paper, mentioned mental depression as one of the causes of bodily disease, and this depression, of course, would be increased by solitary confinement.

Dr. Webster did not refer the occurrence of phthisis to the influence of hot air, but it might produce other chest affections, as bronchitis, which would terminate in phthisis.

Dr. James Johnson referred to the curious fact stated in the paper, that the mortality

in prisons always lessened after the fourth year, and inquired if any cause could be assigned for this circumstance ?

Dr. Baly observed, that it was a fact, that the mortality in the Penitentiary was less in the fifth than the fourth year. It had been noticed, also, in the Eastern Penitentiary of America, that this circumstance obtained ; and in this institution, also, there was less mortality in the fourth than in the third year. He explained this by the fact that those prisoners who were liable to be affected with scrofula fell a victim to that disease before the termination of the fourth year. Those who survived that period were not liable to be thus diseased.

Dr. Cursham inquired how long a time it required for scrofula to develop itself in those prisoners in whom there was no trace of the disease previous to their admission into the Penitentiary ?

Dr. Baly replied that scrofula began to develop itself in the second six months' imprisonment, and increased in severity during the next eighteen months. He possessed only a limited number of facts in regard to this question, but it would appear that the disease gradually declined after the second year of its existence.

Mr. Bransby Cooper inquired what was meant by scrofula, in the paper of Dr. Baly. The term was so indefinite that he wished to know in what way it was employed.

Dr. Baly, in the abstract, had referred tuberculous scrofula to imprisonment. He considered this disease to consist of a deposit of tuberculous matter in the lymphatic glands, the serous membranes, or any organ of the body.

Mr. Bossy, in reference to the inquiry of Mr. B. Cooper, remarked, that Dr. Baly had correctly described the scrofula developed by imprisonment as tubercular cachexy. It shewed itself by paleness, weakness, and general debility of the frame ; and these were so marked that he (Mr. B.) could, in examining a number of men, easily determine which of them had been subjected to imprisonment. Dr. Webster had remarked, that short imprisonment appeared to have a beneficial influence upon health, and this was apparently the case, for, from want of exercise, and the use of fluid diet, there would be an increase of fat. He had found, however, that the improvement in health was not real, for, upon putting these persons to labour, they were incapable of muscular exertion. There was, moreover, a loss of weight in them. These were the persons in whom, if imprisonment were continued, tubercular disease would develop itself. With respect to the prevalence of tubercular disease generally, the mortality from this cause in the hulks had been increased by a circumstance which should be

mentioned. On the carrying of the Emancipation Act in 1834, the black convicts of the West Indies were sent to this country on their way to Van Diemen's Land. They arrived chiefly in the autumnal season, and phthisis developed itself in great numbers as the effect of confinement and cold. This accounted for the large mortality for some time, from phthisis, in the hulks. The cruelty of this plan was represented to Government, and was not persevered in. In addition to this, also, it might be stated, that pardon was not granted to prisoners in the hulks on account of ill health. He differed with Dr. Baly respecting the influence of prison food in the production of diarrhoea, and gave two or three illustrations in point. In one of these he traced the prevalence of this disease to soup containing a quantity of barley-husks; and, in another instance, to the bread used by the prisoners having been made of flour a quantity of which had been ground from wheat damaged by the sea, and which had begun to vegetate. In both these instances the bowel-complaint prevailed during the time the prisoners were partaking of the unwholesome diet, and disappeared on substituting more healthy food. He agreed with Dr. Webster that hot air produced catarrh, and chronic bronchitis, if not phthisis. In the Chelmsford Prison, the prisoners were taken from a cell of high temperature to stand at the cold treadmill, and were again taken to the cell. Catarrh was frequently caused in consequence. This had also occurred in other prisons.

Dr. Webster expressed his satisfaction that Mr. Bossy's extensive experience respecting prisoners coincided with the opinions he had expressed relative to the influence which particular kinds of food produced on the health of the inmates of prisons. In addition to the facts Mr. B. had stated, he (Dr. W.) might mention, that in Bridewell, although situated in a confined locality of the City of London, near Fleet-ditch and Puddle-dock, bowel-complaints, or any serious disease, had not been prevalent, notwithstanding the prisoners were not allowed to take regular out-door exercise. Generally speaking, the men were employed on the treadmill, and the women in picking coire, but their food was of good quality, and the bread excellent; indeed, it could not be purer, as the corn was ground in the prison, and baked at the house of Occupations, with yeast also made on the premises. He (Dr. W.) was likewise gratified to hear that Mr. Bossy entertained the same opinions with himself respecting the ventilation of prisons, and the injurious influence which the breathing of hot dry air had in producing pectoral disease amongst the inmates. Having stated, in the previous remarks he (Dr. W.) had taken the liberty of offering to the Society,

that a large proportion of the prisoners recently pardoned at the Penitentiary were discharged on account of being affected with phthisical symptoms, he would now ask Dr. Baly whether any of these patients had subsequently recovered; for if such were the case, the fact would show that their residence in prison tended materially to produce consumption. With reference to the lunatics sent to Bethlem Hospital from the Penitentiary, it must be satisfactory to Dr. B. to hear, that during last year four individuals formerly under his care in that prison had been cured, and removed from the hospital by warrants of the Secretary of State.

Dr. Baly replied, that in a great number of cases of phthisis at the Penitentiary, apparently hopeless, the disease was immediately checked on the release of the prisoners, many of whom entirely recovered; a favourable change took place almost immediately they were informed of their probable change. These cases shewed, in a remarkable manner, the influence of mind on the progress of disease. Mr. Bossy had, in some degree, misunderstood him with reference to the causes of diarrhoea and dysentery, which he admitted might occasionally be produced by impure food. But when diarrhoea or dysentery were prevalent for several years, they did not then arise from diet, but were always dependent on the locality of the prison. The causes mentioned by Mr. Bossy as productive of bowel complaints could not be always prevalent. Facts which he (Dr. B.) had referred to in his paper proved that his view was correct, for not only were these diseases found to be more prevalent at particular seasons, as in spring and autumn, but when they were epidemic in the surrounding neighbourhood. In these instances the diseases were owing to miasma.

Dr. Gregory suggested that as Dr. Baly was about to furnish other papers on the subject of disease in prisons to the Society, that much benefit would be derived, particularly in respect to age, if he directed his attention to the acquirement of tubercular diathesis in a number of persons under circumstances directly the reverse to those of the prisoners. He thought soldiers offered this opposite condition. He had been struck with the origin of phthisis in the recruits of several regiments, particularly the foot-guards. It was a curious fact, that many of these men, even though carefully examined by the stethoscope, and pronounced healthy, at the end of a few months fell victims to tubercular disease. The announcement of the result of investigation into these cases in Dr. Baly's paper would increase its value, and enhance our knowledge of the subject.

Dr. Baly was obliged for the hint thrown out by Dr. Gregory. He was well ac-

quainted with the prevalence of consumption among the foot-guards, who suffered from this disease to twice the extent as did the cavalry regiments. He did not agree with Dr. Gregory as to their being placed under circumstances the reverse of prisoners; on the contrary, they were subjected to several of the same injurious influences. Nothing, for instance, could be worse than the ventilation of the barracks, particularly those in Portman-street and in the Tower. There was no ventilation whatever in the rooms they slept in, and these were their sitting-rooms also. They mounted guard frequently, and were therefore frequently exposed to cold, as were prisoners. There was another cause which acted also on both these classes, and this was, the listless state of mind which resulted from their condition, and the inactive state of their bodies, both having a tendency to the production of tubercular disease. To these might be added, perhaps, their dissolute habits.

Mr. Cooper regarded the depressed condition of mind of the recruits, conjoined with their severe exercise in drilling, as a further cause of phthisis in these men.

Mr. Probert considered that the well-known indulgence of recruits—who were generally fresh from agricultural pursuits—in drinking, and their contraction of venereal disease, must have an influence in the destruction of their health.

Mr. Macilwain considered Dr. Baly's paper important in reference to the causation of disease and its amelioration. He inquired whether in those prisons in which diarrhoea was prevalent, as the result of locality, the peculiarity was in the soil, or in the ordinary matters of drainage. He made some remarks on the influence of ventilation on the function of the lungs.

Dr. Baly regarded the diarrhoea as the effect, not of imperfect drainage, but of a moist state of ground for some extent round the prison. The Wakefield House of Correction, in which diarrhoea was more generally prevalent than in any other prison of England, was situated in a hollow valley of clay, which was often flooded in winter, and in summer was not quite dry. The sub-soil was clayey, the surface of a rich vegetable character.

ANNIVERSARY MEETING, MARCH 1.

The anniversary meeting was held in the library, and was numerously attended. Mr. Macilwain made a long address, chiefly in reference to the mode of election, and the passing over, as he considered, many older members of the Society, and electing others who were in some way connected with the Council of the College of Surgeons. He mentioned three or four instances in particular. He expressed his regret that general

practitioners should be so little regarded by the Council of the Society, that the name of only one was in the present balloting list. He proceeded to shew by a reference to statistics that general practitioners had never had their due share of government in the Society, and declared that the charter authorized no distinction between the classes of the profession as to their eligibility for any of the offices. He complained of the mode in which papers were occasionally dealt with by the Council of the Society, and thought it a hardship that authors were not, when they were desirous of doing so, permitted to read their own papers.

A vote of thanks was carried to Dr. Cursham.

The President delivered his annual address; after which the following gentlemen were elected.

President.—William F. Chambers, K.C.H. M.D. F.R.S.

Vice-Presidents.—Theodore Gordon, M.D.; Thomas Watson, M.D.; J. G. Perry, Esq.; Richard Welbank, Esq.

Treasurers.—George Burrows, M.D.; Cæsar Hawkins, Esq.

Secretaries.—George Cursham, M.D.; T. B. Curling, Esq.

Librarians.—R. B. Todd, M.D. F.R.S.; Benjamin Phillips, Esq., F.R.S.

Other Members of the Council.—Neil Arnott, M.D. F.R.S.; William Baly, M.D.; T. A. Barker, M.D.; Jonathan Pereira, M.D. F.R.S.; Henry S. Roots, M.D.; Robert Dunn, Esq.; Alexander Nasmyth, Esq.; Edward Stanley, Esq. F.R.S.; Samuel Solly, Esq. F.R.S.; Martin Ware, Esq.

CASES OF EXTIRPATION OF DISEASED OVARIA.

BY DR. EPHRAIM M'DOWELL.

THE operations of Dr. Ephraim M'Dowell, of Danville, Ky., for extirpation of diseased ovaria, having been so frequently quoted of late, and often incorrectly, and the journal in which they were originally published ("The Eclectic Repertory") being inaccessible to the profession generally, we have thought that we should do a service by republishing them.

Dr. M'Dowell's first paper, containing an account of his first three operations, was published in the Eclectic Repertory for April, 1817; and his second paper, containing an account of two subsequent operations, was published in the same journal for October, 1819.

CASE 1.—"In Dec. 1809, I was called to see a Mrs. Crawford, who had for several months thought herself pregnant. She was affected with pains similar to labour pains,

from which she could find no relief. So strong was the presumption of her being in the last stage of pregnancy, that two physicians who were consulted in her case requested my aid in delivering her. The abdomen was considerably enlarged, and had the appearance of pregnancy, though the inclination of the tumor was to one side, admitting of an easy removal to the other. Upon examination, *per vaginam*, I found nothing in the uterus; which induced the conclusion that it must be an enlarged ovarium. Having never seen so large a substance extracted, nor heard of an attempt, or success attending any operation, such as this required, I gave to the unhappy woman information of her dangerous situation. She appeared willing to undergo an experiment, which I promised to perform if she would come to Danville, (the town where I live), a distance of sixty miles from her place of residence. This appeared almost impracticable by any, even the most favourable conveyance, though she performed the journey in a few days on horseback. With the assistance of my nephew and colleague, James M'Dowell, M.D., I commenced the operation, which was concluded as follows: Having placed her on a table of the ordinary height on her back, and removed all her dressing which might in any way impede the operation, I made an incision about three inches from the *musculus rectus abdominis*, on the left side, continuing the same nine inches in length, parallel with the fibres of the above-named muscle, extending into the cavity of the abdomen, the parietes of which were a good deal contused, which we ascribed to the resting of the tumor on the horn of the saddle during her journey. The tumor then appeared full in view, but was so large that we could not take it away entire. We put a strong ligature around the fallopian tube near to the uterus; we then cut open the tumor, which was the ovarium and fibrous part of the fallopian tube very much enlarged. We took out fifteen pounds of a dirty, gelatinous looking substance; after which we cut through the fallopian tube, and extracted the sac, which weighed seven pounds and one half. As soon as the external opening was made, the intestines rushed out upon the table; and so completely was the abdomen filled by the tumor, that they could not be replaced during the operation, which was terminated in about twenty-five minutes. We then turned her upon her left side, so as to permit the blood to escape; after which, we closed the external opening with the interrupted suture, leaving out, at the lower end of the incision, the ligature which surrounded the fallopian tube. Between every two stitches we put a strip of adhesive plaster, which, by keeping the parts in contact, hastened the healing of

the incision. We then applied the usual dressings, put her to bed, and prescribed a strict observance of the antiphlogistic regimen. In five days I visited her, and much to my astonishment found her engaged in making up her bed. I gave her particular caution for the future; and in 25 days, she returned home as she came, in good health, which she continues to enjoy."

CASE II.—"I was called to a negro woman, who had a hard and painful tumor in the abdomen. I gave her mercury for three or four months with some abatement of pain; but she was still unable to perform her usual duties. As the tumor was fixed and immovable, I did not advise an operation; though from earnest solicitation of her master, and her own distressful condition, I agreed to the experiment. I had her placed upon a table, laid her side open as in the above case; put my hand in, found the ovarium very much enlarged, painful to the touch, and firmly adhering to the vesica urinaria, and fundus uteri. To extract I thought would be instantly fatal; but by way of experiment I plunged the scalpel into the diseased part. Such gelatinous substance as in the above case, with a profusion of blood, rushed to the external opening, and I conveyed it off by placing my hand under the tumor, and suffering the discharge to take place over it. Notwithstanding my great care, a quart or more blood escaped into the abdomen. After the hemorrhage ceased, I took out, as clearly as possible, the blood, in which the bowels were completely enveloped. Though I considered the case as nearly hopeless, I advised the same dressings and the same regimen, as in the above case. She has entirely recovered from all pain, and pursues her ordinary occupation."

In his second paper Dr. M'Dowell states that he thought this patient well of her disease: "but she informed me a short time since, that it had been growing for the last 12 or 18 months, and says it is now about the size it was when I opened her six years ago."

CASE III.—"In May, 1816, a negro woman was brought to me from a distance. I found the ovarium much enlarged, and as it could be easily moved from side to side, I advised the extraction of it. As it adhered to the left side, I changed my place of opening to the *linea alba*. I began the incision, in company with my partner and colleague, Dr. William Coffey, an inch below the umbilicus, and extended to within an inch of the *os pubis*. I then put a ligature round the fallopian tube and endeavoured to turn out the tumor, but could not. I then cut to the right of the umbilicus, and above it, two inches, turned out a scirrhous ovarium, (weighing six pounds), and cut it off close to the ligature put round the fallopian tube.

I then closed the external opening, as in the former cases; and she complaining of cold and chilliness, I put her to bed prior to dressing her—then gave her a wineglassful of cherry-bounce and thirty drops of laudanum, which soon restoring her warmth, she was dressed as usual. She was well in two weeks, though the ligature could not be released for five weeks; at the end of which time the cord was taken away; and she now, without complaint, officiates in the laborious occupation of cook to a large family."

CASE IV.—"In April, 1817, I operated on a negro woman from Garard county; extracting a scirrhus ovarium, weighing five pounds. The incision was made near the linea alba: as in cases formerly related, I tied a cord firmly round the ligament, attaching it to the uterus, and cut away the ovarium; but owing to the shortness and sponginess of the part, the cord slipped off before I laid the ovarium out of my hands, and a profuse discharge of blood took place. I immediately drew the uterus to the external incision, and commenced tying up the bleeding mouths separately. This also, in consequence of the diseased state of the parts, proved only of partial efficacy, as several of the ligatures cut through on tying them. I now thought it all over with my poor patient, but arming a needle with a strong ligature, I passed it round the ligament; securing it in its place by taking several stitches over its surfaces as I passed it round, and firmly tied it. By turning her nearly on her stomach I was able to get most of the blood out of the abdomen, using my hand to extract the coagulated portion. The incision was then closed by the interrupted suture, and strips of adhesive plaster. She recovered happily; but I am told her health is not good; the account I had of her was awkwardly given; from what I could learn her complaint is hysterical. This, though the smallest ovarium I have ever extracted, was much more troublesome to the patient than in any previous case. Besides experiencing severe lancinating pains in the parts, she was seldom able to discharge her urine, without getting almost on her head, in consequence of the tumor falling down into the pelvis, and compressing the urethra."

CASE V.—"A negro woman, from Lincoln county, was brought to me in April, 1818, supposed by the different physicians who had attended her to be affected with ascites; she had been under their care about eighteen months. On examining her I could very plainly discover the fluctuation of fluid in the abdomen, and for some months administered medicines for ascites without effect: despairing of the powers of medicines, I at length tapped her, and discharged thirteen quarts of gelatinous fluid, such as I had before met with in dropsical ovaria, of so

thick a consistence that I found it extremely difficult and tedious to discharge it. In two months after I found it necessary to tap again; during the process of discharging it a second time, the opening was frequently stopped by viscid portions of the jelly, which were broken by introducing a probe; when the abdomen was pretty well evacuated, I discovered, with the probe, a firm substance, which, on minute examination, I found to be of considerable size. I at once supposed the existence of a dropsical ovarium, in which I was confirmed on finding the uterus empty by examination per vaginam. Some months after she was again tapped, at which time I made the opening large enough to admit my finger; by which means I was able to ascertain the nature of the disease beyond a doubt. I informed her master what was certainly her situation, and that nothing but excision could effect a cure. My advice was not immediately followed, nor until after she was tapped a fourth time; a week or two after she was brought to Danville to undergo the operation, which was performed May 11, 1819. The diseased ovarium being on the left side, and evidently dropsical, the incision was of course made on the left side. On exposing the tumor, it was found to adhere to the parietes of the abdomen, and to the intestines, by slender cords which were easily separated with the hand, and which caused a slight effusion of blood. To the uterus two strong ligaments adhered; one, the natural ligament, attaching the ovarium to the uterus, the other, an artificial one, attached to the fundus uteri, which appeared to be composed of the above-mentioned slender cords, compacted together. I then tied fine cords of silk firmly round each of these ligaments, discharged the contents of the tumor, and cut it away.

"There were sixteen quarts of gelatinous fluid discharged from the tumor and abdomen. The dressings and precautions were the same as in other cases. The second day after the operation she was affected with violent pain in the abdomen, together with obstinate vomiting. She was bled as copiously as her strength would allow, but without producing any abatement of the pain or vomiting. On the third day she died. On examination after death, the uterus, contrary to expectation, appeared natural and uninflamed, the right ovarium healthy, the silken cords were securely and properly fixed, and not in a situation likely to injure the adjoining parts. Her death had proceeded from peritoneal inflammation. This membrane, throughout its whole extent, appeared greatly inflamed, and the intestines largely inflated.

"I was assisted in this operation by my nephew, Dr. William A. McDowell. Doctors Weizgar, Tomlinson, and Horr, were present.

"On examining the substances we had removed, the contents of the sac presented a variety; different portions of the fluid were of different colours—semi-transparent, white, brown, and yellow. There was also contained in the sac a considerable quantity of hair, which grew from the inner surface. Enveloped in the inner substance of the sac we found a bone, resembling very much in shape the front tooth of a cow.

"From the circumstance of the hair and bone, one or two of the physicians present were inclined to believe the disease originated from an extra-uterine conception, and that all of the fœtus had been absorbed, save the hair and single bone which was found. This question I submit to the faculty."—*American Journal of the Medical Sciences.*

RETROVERSION OF THE WOMB IN THE UNIMPREGNATED STATE.

By DR. HELMUTH.

MADAME B—, 30 years of age, of middle stature, almost always healthy, the mother of four children, suffered since her last confinement, four years previously, from an inconsiderable prolapsus of the womb, which heretofore had not created any inconvenience. At Dr. H.'s visit, upon 15th Dec. 1842, she complained of colic with dragging pains in the abdomen, and feeling generally indisposed; for these symptoms a saline effervescing mixture was ordered, together with warm frictions of essential oils over the belly. On the 22d the patient agreed to submit to a vaginal exploration, which she had formerly declined. The following was her condition at that period: she lay in bed, her countenance red and bloated, complaining of headache, heat of skin, thirst, restlessness, and rather violent pain in the lower part of the belly; the pulse was frequent, (100) small, contracted; no urine had been passed for 24 hours, or any stool for 48 hours. On examination the belly was found distended, and above the pubis an elastic tumor, painful on pressure, could be perceived. Internally the temperature of the genitals was increased; the uterus was felt deeply placed in the lesser pelvis, the vaginal portion and orifice turned to the pubic arch, the body towards the cavity of the sacrum. In consequence of this unnatural position of the uterus, the substance of which moreover was swollen from the unwonted irritation and pressure, the neck of the bladder and rectum were quite compressed, and the discharge of urine and feces hindered. An attempt at reposition *per vaginam et anum* failed, owing to the swollen and painful state of the womb, coupled with the retention of urine and ex-

crement; a repetition, after the urine had been taken off through a catheter, and an endeavour made to remove the fecal accumulation by several injections carefully administered, which however did not penetrate, proved equally ineffectual. The patient was now directed to take a dose every second hour of an aperient mixture containing Epsom salt and castor oil, to apply linseed poultices to the abdomen, in conjunction with frictions of anodyne volatile liniment. To relieve the obstinate constipation some emollient clysters were given in the evening; but brought away very little. On the 23rd, there were increase of pain of abdomen, and fever towards evening, indicative of inflammation of the womb—*metritis*. Leeches were therefore applied to the abdomen, perineum, and thighs, and the bleeding encouraged by the aid of a warm bath; 5 grains of calomel were prescribed twice a day, as also an oily emulsion, and emollient injections within the vagina; the urine being withdrawn twice daily by the catheter. By pursuing steadily the above treatment the inflammation had gradually abated. By the 28th a critical sweat supervened, a little urine passed of itself, as also some slimy bloody feces; the uterus meanwhile, diminished in bulk, resumed its original situation. Progressive improvement followed, menstruation was re-established, and after the use of tonics the patient completely recovered, with the exception of a slight prolapsus of the womb."—*Casper's Wochenschrift*, Oct. 1844.

[This is one of those rare instances of retroversion of the womb occurring in the unimpregnated female. It is interesting in reference to the case of Miss H— M—, lately brought before our readers.—ED. GAZ.]

SUMMARY OF THE TRANSACTIONS OF THE COLLEGE OF PHYSICIANS AT PHILADELPHIA.

March to October, 1844.

THE principal articles of interest in the present No. of the Transactions of the College, are the Annual Report on the Diseases of Children, by Dr. Condie, and a case of death after parturition, caused by rupture of the uterus, by Dr. Henry Bond. This last we transfer to our pages:

April 8th, 1844. At 10 P.M. Dr. Bond was requested to visit Mrs. R—, and was informed by the messenger that she was affected with colic. Mrs. R. had a good form and constitution, and enjoyed good health until this attack. She is 28 years of age; was married on the 4th of last October;

had never menstruated after marriage; supposed that she became pregnant within one week after that event, and expected to be confined in the beginning of the second week in July. About noon to-day she was reaching over a flour barrel that stood end-wise, to pick up something behind it, in doing which she felt something give way, and was attacked with pain in that part of the abdomen where she came in contact with the sharp edge of the barrel. The pain continued all the afternoon and evening, and was supposed by her female attendants to be colic, and, in consequence, ginger-tea and other domestic remedies had been administered. But the pain became worse in the evening, and when the doctor visited her, she evidently had labour pains, but no stools or discharge; he directed her an opiate, rest and cool regimen, with orders to send for him if she was not shortly relieved. At 11½ o'clock, P.M. he was sent for again. The pains had increased, and the os uteri had become relaxed, and more than half dilated. The pains were more distressing than usual in such cases, and she was inclined to keep her hand applied to that part of the abdomen which had come in contact with the barrel. The membranes were very strong, and continued unbroken, until a loose sac of water presented externally, and when broken, there was a gush of a large quantity of liquor amnii. The delivery of the child followed almost immediately afterwards—April 9th, at 2¼ A.M. Soon after this, he began to use the ordinary means to promote the delivery of the placenta, which he continued to do for three quarters of an hour without any effect. There was no sign of its coming—there was neither any expulsive pain, nor the least appearance of any coloured discharge. He then gave twenty grains of ergot, and after a quarter of an hour, twenty grains more. At the end of ten or fifteen minutes more, no uterine contraction had occurred,—at least he discovered none, either by questioning the patient or by watching her motions.

The uterus was so low that he could easily pass his finger within its neck, which was soft and relaxed; but above that, the uterus seemed to have assumed something like an hour-glass contraction, so low down towards the neck, as to embrace in the upper chamber nearly or quite all of the placenta. He immediately prepared to introduce his hand, without waiting longer for the ergot to act. The cord was ten inches long, very large, and firm for that period of gestation, except for a short distance near its insertion into the placenta, where it was very slender. In his attempts to examine the condition of the uterus and to deliver the placenta, the cord was torn

from its attachment. This occurred only a short time before the introduction of the hand. The os externum and the os cervix uteri were so relaxed, that the hand passed with ease until it reached the above-mentioned contraction. This was so rigid as to occasion some delay. During the process of introducing the hand, pretty strong uterine contraction came on, which increased the delay. Whether this was the effect of the ergot, or of the irritation of the hand, is doubtful;—probably it was partly owing to each. Upon passing the hand through the stricture, into the chamber containing the placenta, it was found that this was detached from the uterus in no part, so far as could be perceived. Up to this period there was no sanguineous discharge, except a very little, which was supposed to proceed from the separation of the cord. The doctor proceeded slowly and carefully to detach the placenta, which adhered so firmly as to make the operation tedious. After the whole of the placenta was separated, he found a strong membranous attachment to one part of the fundus, which he could not overcome. It was of limited extent, being less than an inch. He used as strong traction as he thought could be done without endangering a laceration of the uterus. When pulling it, it seemed to yield a little, but, upon examination, there was no sign of its being detached. It occurred to him that, possibly, there might be an hour-glass contraction, embracing a small part of the placenta and membranes, although he could perceive no rounded edge and depression around the adhesion such as he should expect in that case; but to determine this, he applied the other hand to the abdomen, and this examination entirely satisfied him that such could not be the case. He then separated the placenta from this adhering membrane, and withdrew it. The membrane, which felt like a ligament, had such remarkable strength, that the separation was not easily accomplished. The operation occupied three quarters of an hour, and was attended with very little hæmorrhage.

The child lived twelve hours. The foetal end of the cord, as before observed, was very thick, and he tied it, as he thought, very carefully; but in a little while he discovered that, in proportion to the size of the child, there was considerable hæmorrhage, such as might have destroyed it, had it not been discovered and arrested. It had not, however, produced any signs of anæmia.

10th.—Last evening the patient began to be uneasy and feverish,—a cathartic of senna, manna and sulphate of magnesia, in divided doses, was directed. It operated sufficiently during the night, but the febrile symptoms and uneasiness were not mitigated. Tongue a little coated—pulse 110 to 120—

some tenderness in the left iliac region—the uneasiness in the head increased. In the afternoon, the symptoms all aggravated—no lochial discharge. Directed the neutral mixture—v. s. oz. xxiv.—fomentations. The blood drawn exhibited a thick buffy coat and small cupped coagulum.

11th.—Head much relieved since the v. s., but the patient had a very uncomfortable night—tongue has a yellowish white coat, thickest in the middle—had a severe chill this morning at 7 o'clock—pulse 120 to 130. After the application of the fomentation, a copious sanguineous discharge from the vagina came on, which it was thought desirable to promote, therefore the v. s. was not repeated nor leeches resorted to this morning as would otherwise have been done. Directed cal. ipecac. and opium. At 5 P.M. pulse 102; at 11 P.M. 82—all the symptoms mitigated. The pain in the abdomen, last night and to-day, which was almost entirely confined to the iliac region, was intermittent, like after pains.

12th.—In the morning, found her more comfortable in every respect—pulse 80 to 90. No tympanitis or swelling of the abdomen, and the tenderness is chiefly confined to the part before-mentioned—sanguineous discharge has ceased, and the vaginal discharge has become offensive: some confusion of the head in the night and this morning. When visited at 5 P.M. the patient was found to have become worse soon after the morning visit—great increase of febrile excitement and of tenderness of the abdomen—thirst great—began to be tympanitic. Upon examination, found some shreds of membrane in the neck of the uterus, which were removed; one part, however, extended into the uterus, which could easily be seized hold of, but adhered too firmly to be extracted without applying more force than could be done with safety. Some time afterward it came away, and the offensive discharge ceased.

13th.—She began in the night to belch up whatever she drank—pulse very variable—tympanitis increasing, as well as the distress and tenderness in the abdomen. Dr. Meigs saw the patient twice to-day, but it is unnecessary to detail the treatment, which had no influence in controlling the disease. The discharges from the stomach became more and more dark, until they closely resembled coffee-grounds. The patient grew rapidly worse, and died next morning, April 14th, at 4 A.M. about 98 hours after delivery.

Autopsy, 29 hours after death.—The operation was performed by Dr. Goddard, in the presence of Drs. Huston and Bond; and this account of it is chiefly taken from Dr. Goddard's notes. Abdomen alone examined. On opening the peritoneal cavity, a quantity of foetid gas escaped, which

occurrence Dr. G. observed he had never met with, except in cases of perforation of the intestines, or as a result of putrefactive fermentation. That part of the peritoneum, where this gas was contained, was dry and glossy, as if it had been hung up in the open air—colon much distended, and very low in the abdomen. Upon carefully raising the omentum majus, the whole of which was gangrenous and foetid, a black mass, about two inches long and three quarters of an inch wide, was brought into view, one end of which passed into an opening in the fundus of the uterus. At first view this looked like a coagulum of blood, which in some parts had begun to be organized, but which, being drawn out and washed, proved to be a portion of the foetal membranes, with some remains of placental fibres, and the debris of a coagulum of blood—the whole being in an advanced state of putrefaction. The uterus was next examined, and found to be lacerated at the left extremity of the fundus, above and very near the junction of the Fallopian tube. The rupture in the peritoneum was small—about three-fourths of an inch in length, and entirely filled up by the membrane before alluded to. The laceration of the proper substance of the uterus was greater, and its edges were covered with a coagulum partially organized. *The lining of the uterine cavity elsewhere looked well.* The peritoneum showed traces of high inflammation in several parts—about the stomach, among the small intestines and especially at the pelvic region, but appearing comparatively healthy at the anterior portions of the abdomen. There was very little effusion into the peritoneal cavity—there was a small quantity of blackish fluid, with flakes of pus floating in it, in the most dependent portions of the abdominal cavity.

There is, therefore, reason to believe that, when the laceration took place, it was chiefly in the uterine substance, the peritoneum resisting; that the unbroken membranes protruded, like a hernia, through the aperture into the abdominal cavity;—that the contraction of the uterus, after the delivery of the child, closed so firmly upon these, as to strangle them, and to resist the efforts to withdraw them, during the operation for extracting the placenta. This examination explains the difficulty attendant upon the delivery of the secundines; for although the placenta was in no part detached from the uterus when the hand was first introduced, still there did not appear to be any preternatural adhesion of growing of the placenta to the uterus; but the chief difficulty arose from the extraordinary strength of the foetal membranes, and their inextricable confinement. The revelations of this examination were especially gratifying to the doctor, as he had apprehensions be-

fore this, that although the labour was brought on by an accident, the febrile and inflammatory symptoms, and the fatal termination, might have been the consequence of the operation of extraction; although he had proceeded with such caution, that he was satisfied it could have resulted only from the irritation of the protracted operation, and not from any laceration, or other violence done to the part."—*American Journal of the Medical Sciences.*

POISONING BY ARSENIC TREATED WITH HYDRATED OXIDE OF IRON.

BY DR. KRAFFT.

THE chimney-sweeper K—, of B—, kept in the house a mixture of white arsenic and flour, for destroying rats. His sister one evening, during his absence, unwittingly prepared for the family a meal-pap for supper, with the above mixture. Of this the three children partook, about eight o'clock in the evening; one a boy of 13, another of 10, and the last a girl of 11 years old; the remainder was swallowed by the aunt. The children ere long felt unwell, and hurried to bed, but shortly after began to complain of severe pains in the belly, and sense of urgent constriction referred to the stomach. The aunt was similarly attacked. Under aggravation of these symptoms the whole party were seized with violent and continued vomiting. About this time, 10 o'clock P.M., K— returned home, and learned the cause of the mischief. He thought to subdue it by administering copious draughts of milk. But as the vomiting persisted, and the pains became more intense, he got alarmed for their safety, and sent for Dr. Krafft at one o'clock in the morning. From the statement of the messenger, and the nature of the symptoms, there could be no doubt as to the fact of arsenical poisoning; the doctor therefore ordered hydrated oxide of iron to be exhibited to each of the children, in the dose of half a table-spoonful every half hour, and to the aunt a whole table-spoonful at like intervals, with an injunction that word should be sent him in the course of the morning of the result, himself being laid up with influenza at the distance of a league. He received intelligence in the afternoon that the three children were completely recovered; but the aunt still suffered from pain in the stomach, headache, and tremors of the limbs, for which ten leeches to the epigastrium, and internally an oily emulsion, were prescribed. During the day he paid the family a visit, and found all well, comfortably sitting round the stove. The parent spoke in the highest terms of the value of the antidote, and remarked that the girl

and younger boy, just convalescent from an attack of influenza, were almost exhausted with the frightful cramps, lying stiff, with their bodies drawn backwards, the hands and face cold, covered with a clammy sweat, and apparently near death; while the two others seemed almost worn out through continued vomiting, sense of choking, and racking pain of the belly. They had, however, scarcely taken two doses of the hydrated oxide before improvement was visible, which proceeded steadily with each spoonful. The pain of the belly was somewhat obstinate, but the vomiting ceased at once, and was followed by frequent liquid stools; after which the children slept quietly till morning, awaking fatigued, but in good health. The aunt did not get well so rapidly, though nothing more was required in the way of medicine than the leeches and emulsion. The quantity of arsenic contained in the pap could not be ascertained, as K— had deposited the remainder of the rat-poison in the ground.—*Casper's Wochenschrift*, Oct. 1844.

[It is to be presumed that the copious draughts of milk and water must have served to dissolve whatever arsenic remained in the stomach, otherwise the hydrated peroxide of iron would have proved effectless.—*ED. GAZ.*]

AMMONIA GIVEN OFF BY ALBU- MINOUS FLUIDS.

M. TURCK communicated a memoir to the Academy of Sciences, on the chlorides occurring in albuminous liquids. All the albuminous liquids he has yet examined, namely, the saliva, blood-serum, and white of egg, are continually disengaging ammonia. The formation of this gas is due, he thinks, to the simultaneous presence in these liquids of muriate of ammonia and caustic soda, which react unceasingly one upon the other, until the soda completely disappears. In fresh albuminous fluids there is not the least trace of chloride of sodium; it is only in virtue of the above reaction that the salt is progressively formed. In proportion as the soda replaces the ammonia a very singular phenomenon of crystallization is exhibited, which merits the attention of the crystallographer. He concludes by stating that the evolution of ammonia from albuminous liquids performs an important part in the animal economy.—*Gazette Medicale de Paris*, Feb. 8, 1845.

THE NEW BILL.

To the Editor of the Medical Gazette.

SIR,

In your remarks on Sir J. Graham's Bill, just received, at page 718 I think there is

some slight uncertainty as to the absolute right of registered physicians practising in London, if they please so to do. Your words are, "It is not now the intention of the Right Hon. Baronet to repeal the act entirely, but only so far as to exempt from its penalties all physicians who shall be registered according to the provisions of the proposed measures." Am I to understand from this that all registered physicians will be entitled to practise in London without let or hindrance from the College of Physicians? Wherein is to consist the registration? and are all graduates of Edinburgh, Dublin, and Glasgow, entitled to be registered on merely showing their degrees, without any further examination? for it would be a matter of perfect absurdity that such men, several of them growing grey in the profession, and forming nine-tenths of the physicians of the empire, should be required to submit to any examination—to be examined, perhaps, by some who were learning their alphabets, where their older brethren were working hard in an arduous profession. Pray enlighten us on this subject. Country physicians have long felt the illiberality of the London College of Physicians, and few of them have latterly sought admission into its walls; and it is to be hoped by Sir James Graham's bill we may be permitted, if we please, to practise in London without any molestation. I think you would confer a favour upon your subscribers by giving the bill in full; and with every excuse for thus troubling you,

I am, sir,

An old correspondent,
MEDICUS.

March 3, 1845.

[We subjoin the following extracts from the new bill in reference to the points mentioned by our correspondent.—ED. GAZ.]

In clause 32, it is enacted "that it shall be lawful for the said Council" (of Health) "on the application of any person legally practising or entitled to practise at the *end of this session of Parliament*, as a physician or surgeon in any part of the United Kingdom of Great Britain and Ireland, or as an apothecary in England, to cause the name of such person to be registered as a physician, surgeon, or licentiate in medicine and surgery, as the case may be, on production to the said Council of his diploma, license, or certificate, &c."

In clause 30, it is enacted "that all persons who shall be registered by the said Council as physicians, shall be entitled without other license than such registry to exercise or practise physic throughout the United Kingdom of Great Britain and Ireland, and in all other parts of her Majesty's dominions," &c.

Further, in clause 13, it is enacted "that a register shall be kept and published from time to time, under the direction of the said Council, of all persons who shall have been examined, and shall have received and shall exhibit before the said Council, letters testimonial, as hereinafter mentioned, of their qualification to practise as a physician, or as a surgeon, or as a licentiate in medicine and surgery," &c.

QUIESCENCE BY ADHESION.

To the Editor of the Medical Gazette.

SIR,

THE principle, in the animal economy, of quiescence by adhesion, which was suggested in a letter signed ZETA, in your journal of 2d August, if true, seemed to the writer not likely to be confined to that organ alone, as he endeavoured to instance afterwards in the ligaments of the wrist and instep. And to this extension of the principle he might have added the provision apparently of a similar kind in those four muscles of the leg whose tendons pass to the sides and sole of the foot, round the external and internal ankle-knuckle, namely, the peronei longus and brevis on the one side, and the tibialis posticus and flexor digitorum longus on the other. Thus, he considers the crucial ligament and the two malleoli to form not only a system of pulleys whereby indirect motion is effected, but likewise a system of breaks to facilitate repose, without the help of which the act of standing would be one of the most inconvenient and tiresome efforts of balancing that can be imagined.

The present return to the subject is only the fulfilment of my promise; for not being aware that it has met with any notice from the medical press as the enunciation of a new fact in physiology, I am made doubtful of its correctness, and therefore beg you will use your discretion in calling the attention of your readers to the subject by the insertion of this note from—sir,

Your obedient servant,

ZETA.

Feb. 12, 1845.

THE TERCHLORIDE OF GOLD AS AN OUTWARD APPLICATION IN RHEUMATIC-GOUTY AFFECTIONS,

MADE into a salve with lard, has been recommended by Dr. Wilczewski. It is said to relieve the pain often in a truly wonderful manner. The purple stains are speedily removed by washing the part with a little urine; a fact that was discovered by accident.—*Medicinische Zeitung*, No. 11, 1844.

STATE OF THE THERMOMETER,
DURING FEBRUARY 1845.

To the Editor of the Medical Gazette.

SIR,

I SEND you a record of the state of Thermometer, at Torquay and at Brixton Hill, in the month of February, taken under the same circumstances, and at the same periods of the day, as in my communication for January.

The Devonshire climate, as you will see, has borne the test of this severe winter well, the lowest point which the Thermometer marked in the Strand, at this place, in February, being 30 degrees: on the high ground in the neighbourhood I believe it was as low as 24.—I am, sir,

Your obedient servant,
C.

FARRINGTON GENERAL
DISPENSARY.

DR. W. Camps, and Dr. W. H. Brown, have been appointed Physicians to the above-named institution.

ROYAL COLLEGE OF SURGEONS OF
ENGLAND.

List of Gentlemen admitted Members, Feb. 21.—J. Heynes.—C. Andrews.—G. Ayton.—F. R. Gibbs.—A. B. Allen.—S. Le Brun.—G. J. Macklin.—R. S. Rogers.—D. H. Gabb.

APOTHECARIES' HALL.

Gentlemen who have obtained Certificates, Feb. 20.—George Cleveland, Lowestoff, Suffolk.—L. F. Crummey, Stokesley, Yorkshire.—Peter Thornton, Glossop, Derbyshire.—Feb. 27.—J. M. Goodinge, Redruth.—T. R. Cotterell, Charlbury, Oxon.—A. Stansbury, Kingsdown, Bristol.—J. N. Tompson, Totness, Devon.—T. S. Howell.—J. A. Haynes.—H. Woodward, Bicester.

MORTALITY OF THE METROPOLIS.

Deaths from all causes registered in the week ending Saturday, Feb. 22.

ALL CAUSES 1121

SPECIFIED CAUSES 1119

I.—Zymotic (Epidemic, Endemic, and Contagious) Diseases, 176; among which, of—

Small Pox	30
Measles	19
Scarlatina	30
Whooping Cough	33
Croup	8
Thrush	2
Diarrhoea	7
Dysentery	1
Cholera	0
Influenza	3
Typhus	30

II.—Dropsy, Cancer, and other Diseases of uncertain or variable Seat 103; among which, of—

Inflammation	0
Dropsy	35
Scrofula	4
Cancer	16
Atrophy	10
Debility	16
Sudden Deaths	9

III.—Diseases of the Brain, Spinal Marrow, Nerves, and Senses, 164; among which, of—

Hydrocephalus	35
Apoplexy	30
Paralysis	22
Convulsions	44
Insanity	1
Delirium Tremens	0

IV.—Diseases of the Lungs, and of the other Organs of Respiration, 408; among which, of

Pneumonia	104
Hydrothorax	7
Asthma	55
Phthisis or Consumption	156
Diseases of the Lungs, &c.	19
V.—Diseases of Heart and Blood-vessels	34

VI.—Diseases of the Stomach, Liver, and other Organs of Digestion, 73; among which, of—

Teething	15
Gastritis	0
Enteritis	11
Tabes	7
Hernia	4
Disease of Stomach, &c.	8
Disease of Liver, &c.	13
VII.—Diseases of the Kidneys, &c.	9

VIII.—Childbirth, Diseases of the Uterus, &c. 18; among which, of—

Childbirth	15
Disease of Uterus	3

IX.—Rheumatism, Diseases of the Bones, Joints, &c. 7

X.—Diseases of Skin, Cellular Tissue, &c. 0

XI.—Old Age

XII.—Violence, Privation, Cold, and Intemperance

WEEKLY JOURNAL

OF

Medicine and the Collateral Sciences.

FRIDAY, MARCH 14, 1845.

GULSTONIAN LECTURES,

Delivered at the Royal College of Physicians,

By G. OWEN REES, M.D. F.R.S.

Assistant-Physician to Guy's Hospital, and Physician to the Pentonville Prison.

GENTLEMEN,—In the lectures which I am about to have the honour of delivering before you, it is my intention to enter upon the consideration of the blood principally in regard to its physical and physiological attributes, and to combine this with such pathological references as the nature of the subject and the present state of science may permit.

But a short period has elapsed since a confessed belief in the truth of a humoral pathology would have brought disrespect, if not reproof, on the professor, and diseases of the blood were esteemed as existing only in the imaginations of the uninitiated. How far such an opinion may have received support from the state of science at the period to which I allude, it is not very easy to determine, but it appears probable that animal chemistry especially held a low rank among the sciences, and had not given that fair promise of assistance to the physician on which we now have to congratulate ourselves. The greatest fault, indeed, which the most angry humoralist of the present day could consistently find with those who formerly had held his branch of inquiry in contempt would be, that they had not exercised an enlightened faith in the progress of the accessory sciences, and had been content to disregard the phenomena shown by the fluids, because they presented intricacies on which science had as yet failed to throw the desired light. It is scarcely a matter for surprise that, unassisted by the accessory sciences, physiologists and physicians should have had recourse to the assumption of extraordinary agencies to account for the production of the various phenomena observed in the human frame; that, unacquainted

with the extensive range of those sciences which are the legitimate objects of attention in the study of our profession, they should have despaired of ever being able to class the novelties they observed among the effects of any known cause, or of tracing the occurrence of analogous phenomena in the reactions of inorganic nature, and out of the great laboratory of the human organism. It is to be regretted, however, that, instead of patiently waiting in the hope that physics and chemistry might yet unravel the mysteries, the wearied scholar should have invented the power called vitality. It would be well for medicine if the philosophical use of this word were more strictly adhered to in the present day; if, instead of being understood to imply the existence of a power, it were simply used to convey the meaning of a resting-place for phenomena as yet unexplained, and which we may hope will all eventually be recognised as mechanical or chemical effects. Those who are inclined to believe that the functions of the animal organism will be eventually explained on chemical and mechanical principles, and even imitated out of the body, may perhaps be accused of boldness; but is he not rather open to the accusation of temerity who would venture to place a mark beyond which chemical and mechanical phenomena are not to occur? There is one circumstance which appears to have materially interfered with the development of that faith in the power of chemistry more especially, which, had it been encouraged, might have placed us far in advance of our present position. I allude to the fact, that the phenomena observed in the living body have been regarded as in themselves more wonderful than those occurring among the inorganic constituents of the globe. Now it may at first appear a startling assertion to declare that the decomposition of the salts of silver by zinc is in itself quite as wonderful as the most striking phenomenon occurring as the result of organization. It is true that we are able,

in the one case, to adduce analogies without number, and to reduce this result obtained on inorganic matter to a numerous class, but it must not be supposed that such conditions have led us to an appreciation of its essential nature. It is an ultimate fact, that zinc attracts oxygen from the silver salts, and the cause is unknown.

If we consider the so-called vital actions, we shall observe that we are frequently at a loss for analogies among the results obtained by experiment on inorganic bodies, but we must not be too hasty in concluding from this that such phenomena are the effects of a cause entirely separable in its nature from those we recognise for the production of effects in organic chemistry. What I have just advanced may be well exemplified by reference to the phenomena termed catalytic. Catalysis is to organic chemistry what vitality is to physiology; a certain number of inexplicable phenomena occur resembling each other in one or more particulars, and a term has been brought into use indicative of the existence of a power, and under this head have been classed these phenomena, inexplicable on established principles, and presenting all the difficulties in classification which attend the arrangement of the most mysterious actions of the animal organism. We wait for the development of some more general law which shall exclude these unexplained effects, and no longer leave the conventional term catalysis as an opprobrium to chemistry. In like manner, vitality, already deprived of many phenomena once ascribed to its power, may be expected to lose daily in importance, owing to the rapid strides of science, and ultimately to have the whole of its effects grouped as chemical and physical phenomena, which may be initiated out of the living body, or will present such analogies with well-known chemical and mechanical effects as shall at once serve to declare their nature. I may here quote a striking fact connected with the history of the blood, showing the manner in which an advance in physical knowledge has deprived vitality of one of its most curious effects. It has been long known to chemists that the coloured corpuscles of the blood do not yield their colouring matter to serum, though when water is added an immediate solution takes place. Now serum is easily tinged by colouring matters added to it, and presents, in this respect, no peculiarity distinguishing it from other fluids, which makes the effect observed at a first view very unaccountable. Berzelius attempted a chemical explanation of this curious fact. Müller, however, disproved the correctness of his view, and Schultze lately has referred it to the vitality of the red corpuscle, considering that the action of the salts contained in serum stimulated the corpuscle to contraction, and thus

prevented the extraction of its colouring matter; the addition of water, however, diluting the saline solution, he believed diminished irritation, relieved contraction, and allowed the hæmotosine to dissolve from the corpuscle. When, sir, I shall have had the honour of describing, in an after-part of this lecture, the results which have lately been obtained by microscopical experiments, and by taking advantage of the mechanical effects of solutions of various specific gravities, you will perceive that, had the experiment of adding water to serum in order to assist it in dissolving red colouring matter, never been made, you would have been able to foretell that, under such circumstances, the effect would occur as the necessary result of the mechanical conditions presented by the anatomy of the corpuscles, and the action of the laws of endosmose. This action is, in fact, now known to be simply mechanical. I may quote another instance bearing upon the point under consideration in the action of the artificial digestive fluid, a compound which very closely resembles the gastric juice; it is prepared from albuminous structures, and by its action muscular fibre and other alimentary matters are easily dissolved, no other care being necessary to effect this than to keep the mixture at a temperature of the blood (98° Fah.) This fluid may be kept for months in closed vessels, but is still capable of acting in the manner described, showing that digestion is no more than a solvent action, and one concerning the nature of which we may hope to gain valuable information by chemical and microscopical research. It may not be out of place here to mention that it is still, as it ever has been since the fact was first observed, a matter of difficulty to explain the coagulation of the blood, and this action has consequently been attributed to the power of vitality. Now, though our present knowledge, anatomical and chemical, in no way enables us to explain this fact, are we to despair of reducing it to the condition of a result governed by physical and chemical laws? If we study the history of this subject, we shall find that experimenters have certainly been unfortunate in one respect, namely, in not having possessed the advantage of a correct knowledge of the physical structure of the blood, and of the influence of certain physical laws on its condition.

It is true that many whose names have descended to us with well-deserved honour have applied abilities of no ordinary cast to unravel this difficult question, but it must be remembered that such men laboured under disadvantages which are now in great measure removed; and recent discoveries in animal chemistry, together with the advantage to be derived from the use of more perfect optical instruments, place the

observers of the present day in a more favourable position for the prosecution of original research than that enjoyed by the most gifted of their predecessors; and those who now enter on the task which Hunter and Hewson left unfinished, need not feel discouraged by knowing that such men failed where they are hoping to succeed. Though no explanation of the coagulation of the blood has as yet been proposed possessing the simplicity, and admitting of that facility and exactitude of demonstration, which characterises the truth, we have lately gained such important knowledge relating to this effect, that those who are inclined to experiment are placed in a very enviable position for discovery.

As it is my intention on the present occasion to enter on the physical relations of the blood, I shall beg leave, sir, to commence by directing attention to the subject of endosmosis—a power which I hope to shew must exercise considerable influence in directing or controlling both the physiological and pathological phenomena occurring in animal bodies.

Though many years have elapsed since Dutrochet pointed out the curious property possessed by membranes of allowing the mixture of fluids to occur through them, not only by permeation or imbibition, but by a powerful force when any difference in the specific gravity of such fluids exists, still, it is only very lately that this power has been considered in its relation to pathology, and I will therefore shortly state the conditions of endosmotic action. If a tube be closed at one end by membrane firmly secured over it, and then used as a vessel to contain a saline solution, we shall find, on allowing the end secured by membrane to stand in a dish containing either water or a saline solution of less specific gravity than that contained in the tube, that a very rapid action will take place through the membrane, causing the tube to become filled from without, and in opposition to gravity. If we now examine the fluid in the dish, we shall find that a certain quantity of the contents of the tube has descended into it; but the tube will be found to have received a far larger proportion of the fluid in the dish, and if we allow the action to continue, it will at last be filled to overflowing. If we modify this experiment, by putting in the dish a fluid of higher specific gravity than that contained in the tube, we shall find that the tube, instead of filling, becomes rapidly empty, shewing that in both these cases the fluid of high specific gravity attracts that of lower density in larger proportion through the membrane dividing them. It must be remembered that the heavy liquid always passes in a certain proportion through the membrane, but always in small

quantity compared with that of the lighter fluid. Having premised these observations on endosmotic action, I shall now proceed to consider the blood in its physical relations, and in doing so shall regard it as it is generally believed to exist in the circulation, viz. as liquor sanguinis, containing floating coloured bodies designated blood corpuscles or globules. My reasons for following this method are, firstly, to ensure a more thorough understanding of several points to which I shall have occasion to refer; secondly, that I may have an opportunity of showing you that this is really the true condition of the fluid blood as it exists in the vessels; and thirdly, because it is in this form that I believe blood ought to be considered pathologically.

I shall first direct attention to the floating corpuscles. This body has been very differently described by physiologists; some having considered it as composed of solid matter—in fact, that it is a soft solid—while others consider it to possess a vesicular structure. There are considerable and important differences of opinion, however, existing even among those who agree in believing the corpuscle to be a vesicle, some regarding it as made up of a white membrane, containing a fluid of a red colour, while others believe that the vesicle is red, and the contained liquor of a pale tint. The existence of a nucleus in the corpuscle of the human blood is also denied by many; and the exact situation it occupies again divides the opinions of those who believe in its presence. In considering these conflicting opinions, it might at first appear a matter of extreme difficulty to resolve any part of a question depending so much on microscopical evidence; but though there are still many difficulties to contend with in the demonstration of a nucleus, we have fortunately obtained a means of determining pretty certainly two of the points in question—firstly, that the corpuscles possess a vesicular structure, and secondly, that the fluid contained within the corpuscle is red, and the containing membrane white.

If fresh blood be mixed with a watery solution of sugar, salt, or indeed any soluble matter which will not act chemically on the blood, we shall find, on microscopical examination, that certain physical effects are produced on the corpuscles, varying according to the specific gravity of the solution with which the blood has been mixed. Now, presuming the blood corpuscle to be a vesicle or closed membrane containing a liquid, the specific gravity of this must be the same as that of the fluid in which the corpuscle floats, for such is the necessary consequence of stasis; and if, by altering the specific gravity of the fluid suspending the corpuscle, we can alter the condition of the vesicle

itself, by changing the proportion of its contents, in accordance with the laws governing endosmotic action, it is no longer possible to resist the conclusion that the blood corpuscle is truly a vesicle or bladder containing fluid. Experiment has shewn that such effects really occur: thus if we mix freshly-drawn blood with a solution of a specific gravity higher than that of the liquor sanguinis, we immediately observe the form of the corpuscles to alter—they become flaccid and empty, owing to the liquid of high specific gravity having drawn from the vesicle a larger proportion of fluid than it supplied to it, in accordance with the law of endosmosis. If we reverse this experiment, by mixing with the blood a solution of lower specific gravity than that of the liquor sanguinis, a contrary effect is immediately produced, the corpuscles becoming distended and rounded in a very marked degree; more fluid in this case entering the corpuscle, while but little will pass out. If to these corpuscles, so altered by the action of solutions, we now again apply these tests, but on this occasion add the solution of low specific gravity to the collapsed corpuscles, and that of high specific gravity to those distended, we shall find that we are enabled to return each specimen to its former condition, or nearly so. We can always, however, distend the corpuscles which we at first collapsed, and collapse those we at first distended, by treating them in this manner. The effects I have shewn must not be confounded with the action of simple permeation or imbibition; they have no analogy with such effects, but are results identical with those obtained by Dutrochet in his experiments relating to the action of fluids varying in specific gravity when applied to the opposite sides of the same membrane. It has been found by careful experiment that in order to collapse the corpuscles a solution of sp. gr. 1060 is required; but this acts slowly in some cases, and to produce the effect decidedly a solution of 1070, or more, should be employed. Solutions cease to distend the corpuscles when of sp. gr. 1050 to 55, and to distend them well a solution of 1015 or 10 is desirable. Now the specific gravity of the blood is about 1057 to 60; and as the corpuscles remain unaltered by solutions of from 1050 to 1060, we may conclude that the average specific gravity of liquor sanguinis lies somewhere between those two points, which it is a matter of some interest to have ascertained, as it proves that the fibrin of the blood is dissolved, and not suspended in the liquor sanguinis. For were the latter the case, the corpuscle would be rapidly collapsed by solutions of 1050, inasmuch as the serum suspending the fibrin could only have a specific gravity of 1029

to 30, and the corpuscle would of necessity contain a fluid of no higher specific gravity than this.

Having thus, I trust, proved that the blood-corpuscle possesses a vesicular structure, I shall proceed to the examination of its contents, and to describe the method of determining whether the vesicle or membrane be of a red colour, or, on the contrary, that the red colour of the corpuscle depends on the contents of the transparent membrane, the membrane itself being white. I have already shown that liquids of high sp. grav. are capable of drawing out a large proportion of the contents of the corpuscles, and so rendering them flaccid, while liquids of a low sp. grav. draw out but little of their contents, supplying to them a larger portion of fluid than they draw from within, and thus producing distension. Now this being the case, it is evident that if we obtain some means of ascertaining the colour of the fluid floating round these corpuscles, both in the distended and flaccid state, we shall (presuming the contained liquor to be of a red colour) be able to detect in one case a deep red tinting, and, in the other, a very light stain, only communicated to the fluids in which the corpuscles float. It having been proved microscopically that liquids pass in and out of the blood corpuscles in proportions bearing a relation to their sp. grav., that is to say, in accordance with the established law of endosmosis, it occurred to me that as we should be able by treating a collected mass of corpuscles with solutions differing in density, to produce the same effects on a larger scale, we ought to find that the heavier liquid, having drawn out a large proportion or fluid contents of the corpuscles, would be observed of a deep red colour, while the liquid of lighter sp. grav. having drawn out a less proportion of the contents, would be but slightly tinted, having in virtue of its low sp. grav. entered the corpuscle in large proportion, and drawn out but little of its coloured liquid. These experiments were made, and they proved in a striking manner that the liquid withdrawn from the corpuscles was of a red colour; the solution of sp. grav. higher than that of the liquor sanguinis having produced on the subsidence of the corpuscles a supernatant fluid of a deep red colour, while that of lower sp. grav. yielded a supernatant liquor of a pale rose tint. It now could no longer be a matter of doubt that the colour of the liquid enclosed by the vesicle was red, but it still remained to be shown that the vesicle itself was white; and, fortunately, we possessed an easy method of effecting this. It is well known to those who examine the blood microscopically, that when pure water is added to the corpuscles, they are at once destroyed, and the observations above de-

tailed afford an easy explanation of this phenomenon, for a rapid endosmotic action tending to fill the corpuscles must of necessity occur on the addition of water, and the delicate membrane could scarcely be expected to withstand this sudden effect, and would probably burst; at least such was the natural conclusion, on the correctness of which the success of the following experiment was dependent, it being made with a view of examining the colour of the burst cases or envelopes, which had formed part of the now disintegrated corpuscle. The experiment consisted of the following steps:—A quantity of corpuscles were allowed to subside from serum into which they had been introduced, by breaking up in it a portion of crassamentum, and then pouring it off, while containing corpuscles in suspension, leaving behind the coarser particles of broken crassamentum, which were allowed time to sink to the bottom. This mixture was set to stand during several hours, at the expiration of which time the corpuscles had collected at the bottom of the vessel. The supernatant clear serum was next poured off, as nearly as could be effected without disturbing the deposit. This having been done, the mass of corpuscles was thrown into distilled water, and this mixture set aside for twelve hours. The anticipated result was now obtained: the water had burst the corpuscles by rapid endosmosis, the burst envelopes had subsided, and were collected in a white stratum as a precipitate, while the supernatant liquid held the red colouring matter in solution,

I have as yet noticed the corpuscle only so far as its vesicular structure is concerned, but there is another point, and one of great interest, on which much light can be thrown by the last experiment.

The existence of a nucleus in the human corpuscle is a question dividing the opinions of physiologists and anatomists; nor is it a matter of surprise that such should be the case, inasmuch as the appearances presented under the microscope are such as, at a first view, entirely to discountenance such an idea; while, on the other hand, analogy would lead us to believe in a nucleus. Careful disintegration and examination of the corpuscles, however, yield appearances rendering the existence of this body more than probable. I have stated that on rupturing the corpuscles by water, we are enabled to collect a white precipitate. Now if the blood corpuscle be made up of a vesicle enclosing a nucleus, as well as a red coloured fluid, we ought (unless the nucleus be soluble) to be able to detect it by microscopical examination in the white *débris* of the corpuscles forming the white precipitate. I have carefully examined this deposit, and find it made up of three kinds of bodies:—1st,

substances quite such as might be expected to result from the bursting of envelopes, having the appearance of shreds of membrane, some corrugated, others flattened out; 2dly, white bodies, somewhat resembling the blood-corpuscles, thin at their edges, and about two-thirds the diameter of the corpuscles; 3dly, granules, probably due, in part, to serum, and I have reason to believe, in some measure, to partial disintegration of the nuclei. The solid bodies of larger size, I feel persuaded in my own mind are truly the nuclei of the red corpuscles. I have said that these bodies, as existing in the precipitate, are two-thirds the breadth of the corpuscles themselves, and it may be matter of surprise that so large a substance entering into the composition of this structure should not at once show itself when the blood is exhibited in its perfect state under the microscope, but the fact is, that the refractive power of this body is so nearly identical with that of the fluid contents of the membrane by which it is surrounded, that it is not until this condition is altered by processes such as I have described that we are enabled to detect the outline of the nucleus satisfactorily. The bodies I have just noticed as nuclei have been frequently mentioned by micrographers as “corpuscles deprived of their colouring matter,” and, indeed, they have very much of that appearance after maceration in water, being quite two-thirds the size of the blood-corpuscles, and therefore far exceeding the dimensions which most persons would be inclined to allow them. It might be asked what a corpuscle, deprived of its colouring matter, becomes? From that which I have already shown, we see that such a condition cannot well be brought about without bursting the vesicle, and allowing its contents to escape, in which case any solid capable of assuming a definite form, and observed in the *débris*, must be regarded as having once formed part of the perfect corpuscle; and it is this which I consider we must call the nucleus. Those who make a study of the microscopic characters of the blood will, I think, best be able to persuade themselves of the truth of the position I have advocated, by experimenting on the blood of birds, and comparing the results obtained with specimens from the human subject similarly treated. Thus, if a specimen of each kind be placed in a drop of water, on a slip of glass held in an inclined position, and then examined under a powerful microscope, we shall observe in the case of the blood of the bird that the well-known ovoid nuclei have escaped from the burst cases, are floating in the water, and collecting towards the lower part of the specimen, which must be examined with the glass still in an inclined position. In the specimen of

human blood similar appearances will be observed, and I feel inclined to think that a very few experiments, conducted in the manner described, will serve to convince any careful observer of the existence of a nucleus in the blood-corpuscle of the human subject.

The physical relations existing between the blood-corpuscle and the liquor sanguinis, dependent on the specific gravity and the influence of the laws of endosmose, are matters of great interest to the pathologist, and I shall therefore in this part of my lectures enter on physical considerations, and only treat of the chemistry of the subject so far as may be necessary to a full understanding of the view I am about to take. Physical conditions play a most important part in effecting the renovation of the blood, and I shall proceed to show the manner in which this function is performed. It is true that certain obvious means are adopted in order to supply the fibrinous, albuminous, serous, and saline ingredients composing the liquor sanguinis, by admitting into the circulation a liquid which is produced by the digestive process, and afterwards modified by other chylipoietic organs into chyle; but the manner in which the complicated structure of the corpuscles receives nutrition is not at first quite so apparent, though it must form not only an important part of the process, but one immediately necessary to the maintenance of life.

The analyses of chyle and lymph, the one taken from the lacteals before reaching the thoracic duct, the other from the absorbents of the lower extremity, will show you that these liquids contain a large proportion of the ingredients necessary to the formation of liquor sanguinis, and you will perceive that the lymph returning into the thoracic duct (assuming it once to have existed as chyle) has, during its passage through the organism, lost a proportion of each of those ingredients which are most necessary to supply the waste occurring in the body. The fibrinous, albuminous, serous, and saline matters, have been used in the vital processes, and all that may be again wanted returns in the form of lymph into the thoracic duct. The supply of material to the corpuscle, however, to compensate for the loss necessarily sustained during its existence in the circulation, cannot, you will perceive, be carried on with the same facility afforded to the liquor sanguinis, which at once mixes with the pabulum poured in through the thoracic duct. In the case of the corpuscle, we have an organic structure, a membrane containing a coloured liquid, which is to be constantly renovated to assist in the important function of respiration; for, whatever some modern theorists may have advanced, it can scarcely be doubted by any who are experienced in physiology that the change of colour from blue to scarlet, which takes

place in the lungs, is not a principal part in that process, and immediately connected with the absorption of oxygen by the blood. Before I describe the arrangement by means of which this red colouring matter is supplied, I must premise that this substance, which exists dissolved in the liquid contained by the envelope, is the true locus of the iron contained in the blood, the proofs of which will be hereafter noticed.

Now there are two conditions which must be fulfilled in order to supply iron to the corpuscle: in the first place, a liquid containing iron in solution must be brought in contact with it; and secondly, this liquid must be enabled to enter through the membrane freely, or it will scarcely answer the required purpose. If we regard the entrance of chyle into the blood as a means of obtaining the required condition, we shall find that we already know sufficient of the structure of that fluid to enable us to perceive how admirably it is adapted for the purpose in question. The chyle, like the blood, separates, when removed from the body, into two parts, serum and crassamentum. The former of these is a limpid fluid, containing matters intended for the supply of the constituents of the serum of the blood; the latter is a white mass, composed of fibrin intermixed with certain globules and granules.

Now the serum of the blood contains no iron, but the serum of the chyle contains it in abundance; and while the crassamentum of the blood contains iron, the crassamentum of chyle is free from it, or affords only such a trace of the metal as may be accounted for by the adhering serum. The iron of the chyle thus contained in its serum is in a very soluble form, and ready to be applied to the envelopes of the corpuscles for admission through their membranous structure; but another condition is requisite before this can be allowed, viz. there must exist a difference of specific gravity between the chyle and the contents of the envelopes; otherwise this transmission of fluid will scarcely occur, or at any rate can only be effected, after a great length of time, by the slow process of imbibition. The chyle, however, is far below the specific gravity of the liquor sanguinis, and thus, when it enters the circulation, every corpuscle with which it comes in contact will, in accordance with the law of endosmosis, immediately be entered freely by the liquid, which will mingle with its contents, and afford a supply of iron to the red colouring matter. It is obvious that this effect will not only be observed on the corpuscles in the immediate neighbourhood of the opening of the thoracic duct, for this fluid, of light specific gravity, entering the blood, will of necessity dilute the liquor sanguinis, and thus induce an endosmotic current, rich in iron, to pene-

trate into the corpuscle, further removed from the point of entrance. The equilibrium between the contents of the corpuscle and the liquor sanguinis will, in fact, be destroyed, and endosmotic currents induced. It will now at once be seen, that if from any cause the liquor sanguinis be lowered in specific gravity, or the chyle have its specific gravity raised, we can no longer expect to have a normal proportion of colouring matter secreted; and it will be hereafter my object to show the secondary mischief so induced as one of the most interesting of pathological conditions, and one which promises to throw much light on physiological questions of the highest importance. Though the exact nature of the changes which occur for the production of the red colouring matter are still involved in mystery, it is a point not altogether devoid of interest to have ascertained the manner in which one at least of its essential ingredients is supplied. This action of supplying iron to the corpuscles must of course be in active operation during their growth, and all who are familiar with the microscopic appearances of the blood must have observed that the corpuscles differ greatly in size, the smallest being scarcely half the diameter of the larger ones, and presenting a great variety of intermediate sizes. It is probably in this stage of development that the action of the chyle is most energetic.

Having now stated what I believe to be the relative physical conditions of the corpuscle, I will proceed to consider the liquor sanguinis in its disintegrated state, that is, after coagulation, when it has separated into serum and fibrin. This fluid, liquor sanguinis, was first correctly described by my esteemed friend, Dr. Babington, who, in a valuable memoir, read before the Royal Medical and Chirurgical Society, showed its true character; for though Hewson had made the observation that a coagulation occurred when the upper layer of inflamed blood about to coagulate was skimmed off, he did not draw the important inferences from his experiment which a true understanding of the subject would necessarily have brought to his mind, and it was left for Dr. Babington to demonstrate on healthy blood that which had before been observed only in its diseased conditions, and it is to him that we are indebted for that clear view of the condition of the blood while circulating, which regards it as made up of a homogeneous fluid containing floating corpuscles; for he was certainly the first to demonstrate the composition of the fluid, to shew it to be a normal constituent of the blood, and indeed to propose for it the name of liquor sanguinis. If, then, we obtain the liquor sanguinis by skimming from off the blood about to coagulate that portion of bluish

liquid observed close to the surface, we shall see that the vessel in which this is collected will very soon become coated with a layer of fibrin, and that a pellucid serum has separated from the coagulum so formed. Here, then, we have the fibrin and serum of the blood, which, together, formed the liquor sanguinis; and while the corpuscles of the blood were subsiding, we have been enabled to skim off part of this liquid in which they were held suspended.

I have now described the physical separation of the blood, not only so far as it is generally performed, viz. by dividing it into serum, fibrin, and red corpuscles, but, as I have shown, we have, by the addition of water to the red corpuscles, been enabled to divide them into their constituent parts, viz. envelope, nucleus, and colouring matter, the two former sinking as a precipitate, and the latter remaining dissolved in the water used for disintegration. This is a separation effected by purely mechanical means, and is entirely independent of the aid of chemistry. There is a further mechanical separation, however, of the serum, which we effect by simple dilution with water, so that certain constituents of the fluid existing in suspension in its ordinary state are allowed to subside, in consequence of the specific gravity of the liquid becoming lessened, and I have reason to believe that the constituent of serum thus separated occasionally plays an important part in the course of some diseases marked by an excess of water existing in the circulating blood. This solid constituent of serum, owing to its physical qualities, does not disappear with the fibrin when the liquor sanguinis becomes coagulated. It is very easily prepared: we have merely to dilute the serum with about ten times its bulk of water, and allow subsidence to take place, which occupies generally some hours. The clear liquid may then be poured off, and the precipitate thrown on a filter, and washed with distilled water.

We have now divided the blood physically into the following constituents:—fibrin, serum, suspended particles of serum, envelopes, nuclei, and red colouring matter. In effecting these separations, the evidence afforded by the use of the microscope has been indispensable, but I have not yet described all that is to be observed by the use of that instrument.

When the corpuscles are examined microscopically in recently drawn blood, we observe occasionally that semi-transparent bodies of a pale colour occupy part of the field: these are few in number, and it is frequently necessary to search over the whole of the specimen in order to obtain a good view of them. They are larger than the red corpuscles, and have been called the fibrinous globules or corpuscles. When closely ex-

amined by a good light, their surface appears granulated, and marked all over with waving shining lines. When the blood solidifies, these bodies are involved in the coagulation of the fibrin, and form a part of the clot. The use of these corpuscles is as yet undetermined: they are believed by some to be identical with the corpuscles observed in the chyle and lymph, to which they certainly bear a close resemblance; they have also been considered as capable of becoming exudation globules, such as are seen in coagulable lymph effused on granulations, and by a further change to become converted into pus globules. When blood is mixed with solutions of high specific gravity, these bodies do not undergo the collapse immediately produced on the red corpuscles; they are evidently soft solids, and require long maceration before they contract or expand by the application of solutions. When fibrin is deposited from serous fluids, or from the liquor sanguinis, these colourless corpuscles are seen under the microscope enclosed by the fibrin, and they exist in large numbers in the membranes which frequently deposit from serous fluids drawn off by paracentesis. Such serous effusions are, in fact, liquor sanguinis, but they generally contain less solid matter than the fluid of the blood.

The presence of a large number of these fibrinous corpuscles in the deposits of fibrin I have above alluded to, and more especially on healing surfaces exuding coagulable lymph, has led some to a belief that such corpuscles are produced after effusion of the fibrinous liquid, and not ejected from the vessels in the form shown under the microscope. Now it is a difficult thing to believe that a structure so well and firmly organized as the fibrinous and exudation corpuscles appear to be, should be formed by the series of changes occurring out of the body on coagulation. If such be the case, we have no fact of the kind to quote for analogy, and I do not see those difficulties in explaining the transit of such bodies through pores which refuse admission to the red corpuscles, that some consider to be valid objections to the possibility of their exudation as solids.

It would certainly, at a first view, appear difficult to explain how the red corpuscles of the blood escape extravasation, if the fibrinous corpuscles, which are larger by far, are exuded; but if we regard the organization of these two kinds of bodies, we shall, I think, at once perceive conditions rendering such an occurrence extremely probable. If we remember the physical qualities appertaining to a structure such as the blood corpuscle, we shall perceive that they nearly resemble those of a bladder filled with fluid, while the structure of the fibrinous corpuscle more nearly resembles that of a sponge, and it of necessity possesses physical qualities more

adapted to enable it to pass through an orifice of less than its own diameter. This cannot be the case with the blood corpuscle, which is unyielding until its membrane is ruptured, and its fluid extravasated. The number of fibrinous corpuscles contained in the blood may to some appear too small to account for the sudden appearance of these bodies as exudation corpuscles on a secreting surface; but here, again, a little consideration will serve to show that this idea has arisen from a comparison of their number with that of the red corpuscles, which in this respect exceed them greatly, and that we cannot positively state them to be few, inasmuch as it is difficult to draw a single drop of blood that will not show us several specimens fully developed.

OBSERVATIONS

ON THE

NATURE AND TREATMENT OF THE MORE IMPORTANT DISEASES OF THE NERVOUS SYSTEM:

With Illustrative Cases.

BY EDWARD BLACKMORE, M.D. Edinb.
Member Extraordinary of the Royal Medical
Society of Edinburgh, and Physician to
the Bath Penitentiary.

[Continued from page 728.]

SECT. I.—TETANUS, AND OTHER VARIETIES OF TONIC SPASM.

CASE I.—A female, 22 years of age, came under my observation in the spring of 1820, in the sixth month (as it was afterwards discovered), of concealed pregnancy, affected with acute pain in the right hypochondrium and loins, and beneath the right scapula; the pain had been preceded by shivering, and was much increased on pressure. To these symptoms were added a pain referred to the region of the heart, extreme restlessness, nausea, and fever. The muscles of the neck were rigid, and the bowels costive.

A hot bath ordered.

The next day, continued tonic spasm, tremors of the limbs, and subsultus tendinum; the pulse 132, very hard; intense thirst; tongue loaded and parched; costiveness remaining.

Jalap and calomel; bleeding to 39 oz., when syncope supervened; the blood highly buffed, and the serum green.

After this the pain in the side and tremors were relieved. Then followed acute pain at the lower end of the chest,

in the region of the diaphragm, increased by a full inspiration; agonising pain at the neck on attempting to bend the head forwards; pains also at the sacro-iliac symphysis; the pulse 152; costiveness persisting.

40 drops of laudanum.

The 3d day, prolonged sleep after the opiate; on awaking, the pain continued as before; deglutition difficult; the muscles of the throat rigid; easy only for a short time in any position; respiration deep, 36 in a minute; pulse 144; febrile symptoms continuing.

Calomel and opium every three hours, and a purgative clyster.

The 4th, a sleepless night; opisthotonos; two scanty stools only; in the course of the day, the pain and spasms abated; pyalism from the mercury (16 grains) established; skin perspiring; pulse 148; respiration natural.

3 grs. of opium, a purgative, and a warm bath.

The 5th day, sickness in the bath, succeeded by profound sleep and snoring; the head less retracted; pain better, but much tremor of the arms; pulse 140; four scanty stools, with tenesmus; a strong mercurial fœtor in the breath. The warm bath was repeated, and death ensued in the bath. The rigid muscles instantly became flaccid.

Inspection.—The dura mater at the upper part of the spinal chord very vascular, and coated with greenish fibrine.

CASE II.—A small emaciated nervous woman, in January 1826, had dysentery when in advanced pregnancy, and in October she suffered from severe pustulous inflammation of the conjunctiva, and ulcers in the cornea, with *intense headache*, which was relieved at the end of a fortnight by repeated bleedings, calomel with opium, and purgatives. She had two subsequent attacks in November and December, but of a mild character; and in the middle of January, 1827, a fourth attack of inflammation in the cornea, with acute pain at the orbits, which was cured by a blister, purgatives, and lotions.

On April 15th, when much debilitated by grief and poverty, she became attacked, after wetting the feet, with shivering and a sensation of coldness and of *fornication* beneath the integu-

ments betwixt the shoulder-blades, with spasmodic twitchings of the eyes, mouth, tongue, and abdominal muscles, attended with vertigo, muscæ volitantes, nausea, diarrhœa, and backache; the tongue white; pulse full and quick. I saw her in this state on the 22d.

Purgatives and salines ordered, and calomel in repeated doses.

The medicine purged her freely in a few hours; the tremors, however, had increased, with most painful spasms in the legs and belly, dyspnœa, and stiffness in the jaws.

Bleeding to fifteen ounces; the blood buffy and cupped. Dover's powder, ten grains every four hours, to three doses.

The 23d, a cessation of the spasms after two doses of the opiate, but no sleep; dysury, and pain in the bowels, which had been purged; pulse 86, soft; no fever.

Calomel, antimony, and hemlock, in repeated doses.

The 24th, better. The 25th, pain in the head and belly, with costiveness.

Purgative salts, and one dose of calomel and hemlock.

In a few hours she had severe pain in the belly, and in the hind-head, with confusion of thought; the tongue was drawn by spasm; the pulse tense. The 26th, the symptoms remained.

Bleeding to ten ounces; medicines repeated.

The 27th, the head relieved, but severe backache returned; no spasms; the bowels freely purged. In a few hours palpitation of the heart came on.

Digitalis and henbane.

The 28th, palpitation relieved, but a return of headache, with stupor.

Cold lotion to the head.

30th, relieved. May 2d, the 13th day of the attack, twitching and numbness of the limbs.

Purgatives, henbane, and assafoetida.

The 3d, better after purging, yet numbness remaining.

A stimulant liniment on the spine.

The 4th, severe pain in the head and arms, twitching of the eyes, and costiveness.

Purgatives.

Then severe cramp in the belly, and in the mouth, impeding speech, and an

aguish paroxysm; the pulse very quick and tense.

Bleeding to twenty-four ounces; the blood buffed and cupped. Sixty drops of laudanum, one grain of opium, three of calomel, and six of antimony, were then given in the course of eight hours, with relief of the cramp.

On the 5th, a sleepless night from headache; thirst urgent; tongue furred; costiveness; and the pulse quick. A purgative then procured four dark stools, with relief of the head; but spasms of the abdominal muscles continued, with a sensation of coldness in the face.

Mercurial antimonial ointment on the spine. Fifteen grains of calomel at a dose.

In a few hours complete relief of the cramp, followed by sleep. On the 6th, a return of pain in the middle of the back, and at the præcordia, impeding respiration; numbness of the legs, and a feeling of loss of power, but not really a loss of voluntary movement: a tingling and spasmodic motion of the fingers and toes; the urine turbid, and costiveness since taking the calomel, twenty-four hours ago; no ptalism; pulse softer.

Inunction continued, and friction, which relieved the back-ache.

The 7th, a restless night; a feeling of creeping beneath the skin. The back pustulated by the ointment, and the pain then relieved; the mouth very sore from mercury; the bowels purged.

Remedies intermitted.

Then difficult respiration from spasm. The 8th, pain betwixt the shoulders; salivation continuing. The 9th, much better. This improvement continued for the next seven days, but the legs felt sleepy and cold. Convalescence was perfect after a month's illness.

Practical men will require no apology for the lengthy details of this very extraordinary case, which, viewed in connection with the foregoing, cannot fail to be highly interesting.

CASE III.—A gouty gentleman, in the spring, got pleurisy from cold; for which he was bled twice moderately, and blistered with relief. Having, through dread of a relapse, taken only a very slight diet, he became affected, about the twelfth day of the illness, with sudden and alarming exhaustion,

for which a large quantity of wine, brandy, and ammonia, was given; diarrhœa then supervened, and was stopped by opium and catechu; but the vital power again sunk after a fit of pain in the stomach with vomiting. After using a large quantity of Madeira, violent spasmodic action of the face and arm came on, with sleeplessness, and extremely fetid stools: he was allowed, at his own desire, a quantity of soda-water, by which the purging was alleviated; then, after stripping off a flannel shirt, he was affected with laborious breathing, and severe spasmodic action of the respiratory muscles, and with pain in the seat of the diaphragm; this was somewhat mitigated by three grains of opium, but dreadful tetanus supervened, and in a few hours he died.

CASE IV.—A married woman, 26 years of age, on November 11th, 1831, was affected with shivering, vertigo, pain in the belly, and purging. On the 13th, acute pain in the head and limbs, with vomiting. On the 14th, seen by a medical man, who ordered the head to be kept hot, and gave some cordial medicine; on the next day she was seen by another practitioner, who ordered bleeding to 12 ounces, leeches to the head, calomel, jalap, and croton oil, the bowels being very costive. The next day I saw her in complete trismus, with acute pain in the head and belly, the eyes projecting, the pupils dilated, the bowels purged.

Cupping-glasses, and mercurial ointment on the spine, antimonials, purgatives, and clysters.

17th.—Much relief after the cupping and purging; eyes and pulse more natural; and now able to open the mouth, and to speak well.

Salines with colchicum.

Convalescence confirmed in a fortnight.

CASE V.—A scrofulous girl, 15 years old, of a precocious mind, was seen by me in 1844, with the wrists affected with swelling and erythema, (without pain on movement,) the head and fingers, feet, and toes, in a state of spasmodic flexure, admitting, however, of being gently extended. She has also occasional severe spasms in the larynx, (like spasmodic croup, of which two of the family had died,) attended with a sense of suffocation if she attempted to

speak in the paroxysm, but the crowing sound was not always heard: there were also paroxysms of dumbness, in which the tongue was seen to be affected with severe spasm. These affections were intermittent, but recurred frequently. The eyes were large; the pulse, 40, small, tense; the bowels for some weeks affected with diarrhœa, and the stools devoid of bile. Menstruation for the first time occurred six months before I saw her; and it had recurred three times.

The head shaven, and an evaporating lotion applied; milder mercurial ointment, with iodide of potassium, rubbed on the region of the liver: infusion of rhubarb with alkali taken.

All the spasms ceased after applying the lotion to the shaven head; but catarrh afterwards supervened, and the diarrhœa became more severe, and quickly sunk her.

CASE VI.—A lady, about 40 years of age, was subject sometimes to hysterical symptoms and fits of loss of power over the muscles, with a feeling that she should fall if she did not instantly lie down; the limbs then became cataleptic, and fixed in the most extraordinary attitudes. She was sensible of the approach of the fits, and retained her consciousness in them. At times, when reading, the eyes would become fixed on a word, and she felt as if she could not take them off the page. In the paroxysms the pulse was weak. Large doses of cinchona were given without benefit; and in three years the disease passed into a confirmed mania.

CASE VII.*—A girl, aged 9 years, in the beginning of March, 1820, was attacked with pain in the head and left side of the abdomen, and retraction of the umbilicus; which continued for three weeks, abating only during the night: the eyes also were wild and staring, and the cornea at times turned spasmodically upwards under the orbits. In a week more she had also hysterical convulsions, and loss of speech after the first paroxysm, which continued to the next attack, and during one of these fits she lost the use of her left leg. When seen by me, under the care of a physician now deceased, on May 1st, she was affected with convulsions of the bowels, globus hysteri-

cus, blindness from the state of the eyeballs above mentioned, pain at the epigastrium; the left leg still powerless, contracted, and painful on being stretched, but not smaller or colder than natural; the bowels costive; pulse 120, small and weak. Purgatives, bleeding, and leeches to the temples had been employed.

5 grains of calomel; infusion of senna.

4th.—Copious slimy fetid dejections passed with great relief of pain in the abdomen.

Purgatives continued.

6th.—A fit of hysteria threatened, but prevented by terror; pulse 112, stronger; tongue clean. Purgatives of aloes, gamboge, and rhubarb, continued to the 12th, when the stools were more natural; the left eye then became inflamed and painful.

Leeches, a blister, Goulard's lotion, and purgatives.

25th.—The inflammation was relieved, but both eyeballs remained in the same state of spasm as before.

Extract of henbane applied for 12 hours above the right eyelid.

On the next day the lids of that eye violently opened themselves, and the pupil resumed its natural situation: the left eye remaining as before.

The henbane applied to both eyes.

17th.—Both pupils in their natural situation: the left eye again inflamed; bowels opened by the purgatives.

Leeches to the eye, the henbane and purgatives repeated.

28th.—Both eyes moveable at pleasure, and free of spasm; inflammation less; the contraction of the left leg still unaffected; copious purging from large doses of the purgative.

Lotion and extract of henbane to the eyes; the tincture rubbed on the affected leg.

19th.—After the use of the henbane the left leg became relaxed, and she could walk, which she had not done for six weeks.

20th.—Pain of the leg, ascribed to over exertion; inflammation of ball of left eye better, but its lid inflamed; motion of eyes perfect. The henbane and purgatives were continued to the 23d, when she was convalescent.

SECT. II. CONVULSIO.

CASE VIII.—A female, aged 29, was

* This case I saw in the practice of a physician deceased.

affected at the beginning of 1827 with symptoms of croup (as it was thought by her surgeon, who bled her for it); and in September with loss of voice, which continued to December 4th, when she came under my care, complaining also of a sense of difficulty in swallowing at the cricoid cartilage, and a feeling of a lump at the larynx, with rapid and violent respiration, in the form of quick and incessant panting and sighing, with a dull murmur in the trachea. On making the effort, she could utter a dull voice, but she could not command the diaphragm so as to speak plainly, and the attempt excited pain at the præcordia; she had also severe pain at the margin of the ribs, and in the back, apparently in the region of the diaphragm, and she could not lie on the left side; no cough; the pulse quick and tense; the appetite ravenous. She had intermissions of the panting for a fortnight at a time, but the loss of voice and pain at the præcordia were constant. The paroxysms were singularly periodical, coming on a Saturday, and going off on the Monday week following. (The patient a person of credible character.) The present fit came on a few days ago, during menstruation, as was usual in former fits. The panting ceases only on sleep; the menstrua are irregular in their continuance, and generally scanty; the bowels costive; the tongue white; no fever; no sore throat. She has used a blister.

Calomel, with opium, to salivate; salines; a blister on the præcordia.

The 7th, still much pain and tenderness at the sides of the abdomen; occasional pain in the head, neck, and back; sleep disturbed; the sighing and panting violent and incessant; voice stronger; bowels purged of dark slimy stools; no salivation from eight pills.

Medicines as before; Ung. Hydrarg. Camphoratum cum Belladonna.

The 9th, breathing less rapid and less violent.

10th, the fit ceased suddenly, having lasted ten days; still much tenderness at the præcordia, and sleep troubled; pulse 60; bowels regular; mouth sore from the mercury.

Infusion of gentian, and valerian, and camphor; friction of the back and sides.

The 17th, slight tenderness at præcordia; else quite well.

Compound scammony powder, with aloes; quinine with valerian.

She says that the disease has intermitted on former occasions without using medicine. It comes on generally a day before the menstrua, beginning with a frightful dream. She has had seven paroxysms in the last eight months.

Jan. 1st, 1828.—At the end of the month the paroxysm returned, and was arrested suddenly on applying twelve leeches to the throat. It again, however, occurred for three successive months, when she was bled; after which it ceased for nearly two years, and her general health was good. At the end of December, 1829, it recurred in the usual manner at the menstrual period, the menstrua being scanty; and it intermitted at the usual time. She was premonished of the attack by a loss of feeling in the face and limbs, so that things dropped from the hands, yet no loss of muscular power; she had also disturbing dreams, and habitual costiveness.

On February 10th she was attacked with vertigo, loss of voice, a spasmodic action of the lips, so as to whistle clearly and involuntarily; the breathing very quick, with a frequent full pulse; menstruation just now ended, and scanty; bowels costive.

Bleeding; purgatives; rest in bed.

The 12th, great and sudden relief after the remedies.

Cupping-glasses on the neck; antimonial ointment on the shaven occipital region; purgatives of blue pill and aloes.

In March she was well.

CASE IX.—A lady of superior mental powers, and strong muscular energies, in the beginning of 1842, after protracted mental and bodily exertion, caught a feverish cold, which was followed by severe symptoms, regarded as hysterical, for which tonics, camphor, and wine, were employed. After four months her health improved, and continued so to the following spring, when a similar attack recurred, and lasted again for four months. The menstrua were usually regular, sometimes copious, and attended with "nervousness" and headache; the bowels habitually very costive, and she was liable to sudden "fainting fits," in which the muscular powers were more affected than the pulse. In February,

1844, after a cold, she was again the subject of severe convulsions, resembling hysteria; and the functions of the liver and bowels were very imperfect. Her medical attendant prohibited all cordials and high living, cut off the hair, applied a cooling lotion and leeches occasionally, and gave prohibitory purgatives, with the best effect at the end of three weeks. After this, as the convulsive fits were at times severe, and the system seemed weak, calumba with ammonia was given, and then nitric acid, and acetate of morphia, not neglecting aperients. By these means she escaped the fits for a fortnight, and was able to enjoy exercise in the open air in a wheel chair. At the beginning of April she was more particularly under my observation; the natural functions were much improved, but the tongue remained very white, and the pulse small and quick. When I visited her she was in the horizontal posture, which she thought herself obliged to retain, in order to keep off spasms and an uneasy feeling in the head. On raising herself, at my request, she became suddenly affected with a violent spasmodic action of the head and arms, whirling the body around on the face, without loss of consciousness or hearing; this fit was preceded by a feeling of furiousness, as if an irresistible impulse came over her; in ten minutes she regained her usual state. She believed that the effort to rise, on being requested to do so, and not any mental emotion, was the cause of the fit; yet she could at times, when a spontaneous desire led her, rise from the sofa and walk across the room; she could also dress herself, and sit some time on the *chaise percée*, without inducing the fit.

The disorder was considered to arise from vascular fulness, and irritation at the cerebellum and encephalic portion of the spinal chord, and not to be of a nervous hysterical character. Mild doses of calomel, with soda and aperients, were ordered, and a succession of blisters on the neck and occipital region alternately; the cooling lotion on the shaven head continued, and a few leeches occasionally. On the 7th she was better. Once the fit had returned from fixing her eyes intently on an object. The torpor of the bowels required stronger purgatives; the uneasy feeling in the head was always

relieved on resuming the horizontal posture. On the 29th her state was improved, and she had enjoyed the chair exercise; but the paroxysm was brought back on a molar tooth being extracted. In a few days the fit returned severely, from the irritation of boils induced by the repeated blisters.

On May 7th, during my visit, she was again affected with a severe convulsion, turning the body impetuously round on the right side, as was usual. She does not know at the instant what she is about to do, but feels in a fury, and says that the movement is irresistible. Leeches and iced water had given sensible relief to the head; and when out of doors in the chair, she could get out and walk; but when in the house she was obliged to lie incessantly flat on the sofa. A weakness and dull aching of the right arm and leg were now complained of, which had existed slightly for many months, with a feeling, on sitting in a chair, that she should slide down towards the left side; and this leg is also colder and less sensible than the left, which she calls now her "well side;" she has also some difficulty in controlling the thoughts; the tongue more furred and white; some uneasy feeling in the head this morning, which was relieved after the convulsion.

In a few days she had an ordinary hysterical fit, from mental excitement. It was then determined to discontinue the cold to the head, to give the compound rhubarb pills, and half a grain of extract of belladonna, thrice a day. After this a change was obvious in the character of the disease; the spasm was less violent and less frequent, and slight hysterical symptoms succeeded; there was also slight narcotism from the belladonna. On the 18th, the liver being torpid, the narcotic was exchanged for alteratives. The right limbs were now less paralytic, but the thermometric temperature of the right leg, that is, of the affected side, as observed twice a day for a week, was oftentimes ten degrees higher than that of the left; *e. g.* the right leg 90°, the left 81°; or the right 80°, the left 71°; and afterwards the heat of both legs became equal, with a corresponding improvement in other symptoms, except that a departure from the horizontal posture could not be borne. In June there was a considerable improve-

ment, but still a sense of weakness and aching in the right arm on using it much in straw-platting or writing; and the left leg now felt hotter than the right. Her general health was good. On one occasion a severe convulsion was brought on by placing her on an inclined plane, and in it the pulse became very low; it was preceded by a feeling of choking in the throat, and of heat about the head, and a quivering of the eyebrows and eyelids. On fanning her, also, another slight fit occurred. Her cheerfulness and mental energies were now as great after the fit as before it; formerly the paroxysms were followed by exhaustion.

The shower-bath and enemata daily; and many hours to be passed in the open air.

I afterwards consulted my valued friend the late Dr. Abercrombie, of Edinburgh; and at his suggestion a crucial incision was made in the scalp, at the side of the hind head, where a tender spot was found, and an issue established; extract of stramonium was also given, and the bowels kept acting by aloes. After this she was entirely relieved of headache, from which she had long suffered more or less; and the spasms very much subsided,—but an attempt to grasp any object firmly with the right hand would induce a threatening of them.

At the middle of July small doses of the citrate of iron were given, for debility; and when combined with blue pill and colocynth, the tonic suited well. She was then taken to the seaside for a month; the issue kept discharging; the shower-bath and medicines continued; and to the end of November her amendment was gradual and satisfactory, yet still not amounting to recovery.

[To be continued.]

TREATMENT OF FISTULA IN ANO BY LIGATURE.

To the Editor of the Medical Gazette.

SIR,

I BEG leave to submit the following method of using the ligature in the treatment of fistula in ano, in the hope that it may be acceptable to some of your readers.

I have made trial of this plan during the last twelve months, the results of which, if worth notice, I hope to communicate at a future season. I employ a fine metallic wire of silver or platinum. Having passed a probe director (one of Sir Benjamin Brodie's) along the fistula and through its internal orifice, its point, being very flexible, is readily directed downwards and out at the anus by the finger previously introduced within the rectum; the structures to be divided are now upon the instrument, and, as it were, everted. The wire is then passed along the groove of the director, and the ends are twisted together until a very moderate compression is exerted upon the enclosed parts. It promotes the personal comfort of the patient to leave the twisted ends rather long, and to fix them on the sacrum with a cross slip of adhesive plaster. This trifling arrangement allows the buttocks to lie perfectly apposed, and he (the patient) is free from the disagreeable sensation of an interposed body or rough point, and visits the closet more comfortably. All that remains to be done is to twist up the ligature as it becomes slack, and in a week, or a little more, it is free. I do not confine the patient altogether: it is, however, advisable to keep him on the sofa for the first twenty-four hours, as erysipelas might arise in a bad subject, and also to limit his movements considerably during the entire treatment.

I forbear at present from entering into any detailed consideration of the merits of this method. Any advantages it presents must be obvious to every surgeon. I may, perhaps, remark that I have found no strong reason to prefer it to the knife, and I think that the plan of presenting the parts for division upon Sir Benjamin Brodie's probe director, and dividing them with a good sharp bistoury, not with scissors, as he recommends, is an operation so short, simple, and effectual, as to leave nothing more to be desired; and I am furthermore of opinion that we are much indebted to that gentleman for having so simplified the treatment of fistula, especially in that class of cases where long sinuous tracks have been permitted to form.—I am, sir,

Your obedient servant,

JOHN LOMAS.

Manchester, March 6, 1845.

ON THE
IMPORT AND OFFICE OF THE
SEROUS MEMBRANES.

By R. WILLIS, M.D.

(*For the London Medical Gazette.*)

WHEN we contemplate the general arrangement of the organs which compose the bodies of the more perfect animals, we see particular care taken that one part should be separated from another by intervening spaces, or cavities, as they are called; that wherever there happens to be any considerable thickness of parts, these should either be surrounded by the common integument, or should be partitioned off from one another, and their surfaces invested with a delicate membrane of the particular order characterised as serous membranes.

It is not very obvious, from aught we know, wherefore the brain should have been inclosed within a serous cell, as we find it; and still less wherefore it should have been formed with an extensive cavity in its interior. I venture to say as much in regard to the viscera of the thorax and abdomen generally: it is not very evident why the heart and the lungs have been hung loose within especial sacs; wherefore the liver and spleen are suspended from the top and side of a great cavity. The usual interpretation of the arrangement observed in the visceral cavities is, that all exists for the sake of facilitating motion. But there is no motion or gliding of parts on one another within the cranium; the lungs glued to the walls of the chest would have followed the ribs in their rise as certainly as they do according to the arrangement as it now stands; even the heart in its action does not move through a space nearly of the same extent as many of the long muscles of the limbs in their contractions—the biceps brachii, the sartorius, the gastrocnemius, for example, which are all nevertheless connected at every point, by means of cellular tissue, with the parts around them. The intestines, indeed, could not very readily have propelled their contents had they been less free than we find them. But the liver and spleen needed not, apparently, to have been placed in the same circumstances as the intestines, *i. e.* hung

loose into a cavity, being connected with the body by but a small part of their surface. They have no movements to execute, and they might, we should suppose, have as well been excluded from the peritoneum, and braced down in their seats behind it, as we observe the pancreas and kidney to be. Doubtless there is a cause for, an end to be answered by, the arrangements particularly indicated, over and above any that may perchance be connected with the making motion more easy. What may this cause, what may this end be?

I am disposed to view the serous membranes as internal substitutes for the external common integument, and the fluid that perpetually bedews the surface of these membranes as having the same effect as the perspiration, the purpose of the cutaneous exhalation and of the serous exudation being identical; viz. the preparation of the conditions by which the fluid shed from the capillary arteries finds its way, in principal part, back into the circulation.

In a previous paper, on the Special Function of the Skin, I have shown the influence which the extensive system of sudoriparous glands exerts in this direction, by dissipating so much of the watery element of the blood. With regard to the serous membranes a different arrangement was required. The exudation from them cannot pass off in the form of vapour into the atmosphere; it is, therefore, collected and carried away by a set of vessels especially provided for the purpose, being imbibed or taken up by them in virtue of a general physical law. These vessels are the absorbents, which, as complementary to the veins, are in particular relation with the watery parts of the plasma, or liquor sanguinis, which passes through the parietes of the capillary arteries at every point, charged with the elements of nutrition appropriate to all the tissues composing the body. These tissues select what they require from the plasma that bathes them, and, at the same time, doubtless set free certain effete matters—carbon in the form of carbonic acid, hydrogen in the shape of water and of bile, and azote in the fashion of urea, all of which, dissolved in the lymph, are taken up by the absorbents, and, being thrown into the general current of the

circulation, are by and by sent for elimination by organs especially destined for the purpose—the lungs, the liver, and the kidneys.

Nutrition, in this view, presents itself to us under the aspect of an universal secretion; the fluid contained in the lymphatic vessels may be regarded as the product of the peculiar vital act that is performed by each constituent atom of the body, in the same way as we look on the urine as the product of the peculiar vital act of the kidney, upon the bile as the product of the peculiar vitality of the liver, and so on. The walls of the absorbent vessels have an affinity for the watery fluid with which they are bathed, in the same way as the empty intestine of an animal placed in water has an affinity for that fluid, and becomes distended with it. Abstracting watery fluid, they have the effect of rendering the current of blood which is returning to the heart more dense than that which is quitting it, and so secure the perfect drainage of the tissues at large by the medium of the capillary veins; for the lymphatics themselves do not appear in any case to penetrate the substance of organs, and are nowhere of dimensions so minute as to make them invisible to the naked eye.

The relations of the absorbent system at large with the capillary circulation, and its subserviency to preparing the conditions by which the endosmotic transference of fluids from the outgoing to the incoming currents takes place in internal organs, appear to be particularly indicated by the manner in which it is finally connected with the blood-vessels. The watery fluid appropriated by the absorbents is not poured into the veins in the vicinity of the parts and organs where it is collected: this would have had the effect of attenuating the returning current, and undoing all that had been done; it is only restored to the blood as the common torrent is entering the heart, at the nearest eligible point, it may be said, to that organ, from which it will be immediately sent to undergo exposure in the lungs, and besides the special purgation which it then receives, to lose so much water as will give the blood of the pulmonic veins a somewhat greater density than that of the pulmonic artery, and so effect the drainage of the delicate tissue of these

organs; this is, in fact, probably the end of the pulmonary exhalation which, as is known, amounts to several grains per minute, to several ounces in the course of the four-and-twenty hours.

These views of the end and office of the absorbent system displayed upon the serous membranes, and of these membranes themselves, as contrivances for accommodating absorbent vessels—seem to acquire support from the singular development of the absorbent system, which we observe in tortoises, lizards, and serpents, in which the common integument is obviously unfitted for the elimination of water. Whether there be a corresponding increase in the number and magnitude of the absorbent vessels in higher animals covered with a horny or imperious integument, such as the manis and armadillo, I do not know, but I should anticipate that there was.

The object of this short note being physiological, I but allude in very general terms to the singular amount of disturbance which ensues in the system generally upon any implication of the functions or structure of a serous membrane—upon inflammations, adhesions of opposite surfaces to one another, &c. &c. The mischief in such circumstances is commonly ascribed to interference with the motions of the organs implicated; but it certainly depends in a much greater measure upon something else: the nutrition, the vitality of the organs concerned, are compromised; the conditions essential to the access of the nutrient fluid, and to the removal of effete matters, are interfered with, and hence it is that we have the great amount of general constitutional disturbance first, and the constantly fatal effects in the end, which accompany lesions of the serous membranes.

PECULIAR FORM OF DISSECTING ANEURISM OF THE THORACIC AORTA.

By ROBERT L. MACDONNELL,
Licentiate of the King and Queen's College of Physicians, and of the Royal College of Surgeons, Edinburgh.

A WOMAN, about fifty years old, an inmate of the South Dublin Union, got permission to go out into town, and remained absent for six or seven hours.

On her return in the evening, she ate her supper as well as usual, and nothing remarkable was observed about her. She went to bed at the usual hour, and slept well till towards morning, when she awoke, complaining of excruciating agony in the epigastric region. The resident medical officer visited her, and from the fact of her being subject to attacks of colic, ordered her an anodyne draught, and warm stupes to the abdomen. In about an hour after his visit she suddenly expired; and on examination, the following appearances were detected:—

The pericardium, on being opened, was found to contain about four ounces of serum, tinged with blood, and some coagula; the membrane was, in other respects, healthy and free from any trace of chronic or recent inflammation. Toward the apex of the pericardium, we were struck with the remarkable appearance presented at the origin of the great vessels, where there was a large and firm mass of coagulated blood completely surrounding them, and bound down by the thin layer of serous membrane, which passes up from the heart along the vessels, to be reflected on the fibrous layer of the pericardium. This coagulum was firm, of a dark colour, and uniform consistence; the membrane covering it was quite transparent. We next cut into the left ventricle, which was both dilated and hypertrophied, and then we slit up the aorta as far as the descending portion. The semilunar valves were all in that condition termed atrophy, viz., they were perforated in different parts, but more especially towards their free margins, with small, round, and oval-shaped holes; and in other situations they were very much thinned. The aorta, in the situation of the attachment of the valves, was healthy; but about an inch from this situation, we discovered a laceration extending transversely, and with edges as well defined as if cut with a scalpel; it penetrated the internal and middle coats of the artery, but left the external one quite whole; it was one inch and three-eighths in extent, and from it a probe could be passed downwards, between the external and middle coats, as far as to a level with the upper border of the semilunar valves; but farther than this, *i. e.* behind the sinuses of Morgagni, it could not be passed. The

orifice of this slit was partially closed by a coagulum of pale fibrine, and on tracing this up we found that it lay between the external and middle coats of the vessel, but did not extend far, and was not attached. We then passed a probe upwards, and found that it advanced as far on the right side as to the division of the innominata, and for about half an inch along the course of the left subclavian and carotid arteries, to which extent the middle tunic of these vessels was separated from the outer one; but the space was not occupied by a coagulum, it appeared as if the separation had been the effect of a violent pumping of blood between the coats of the vessels, which had afterwards burst into some other situation, leaving this space empty except towards the laceration, where, as I before stated, we found a pale fibrinous clot.

On proceeding with the dissection, we found the opening in the cellular coat, through which the blood escaped; it was round, about the size of a fourpenny-piece, and was filled with a dark coagulum, which extended downwards, closely embracing the aorta, and separating this vessel from the pulmonary artery at the exact point where, in health, they lie in apposition. In this situation the coagulum exercised a considerable compression on the pulmonary artery, by which the vessel was much flattened. The coagulum lay beneath all that portion of the reflected layer of pericardium, extending from the *zonæ tendineæ* of the right and left ventricles to where it is reflected on the under surface of the fibrous layer of the membrane. The serous membrane was perfectly whole, except at a small point corresponding to the junction of the right ventricle with the left auricle, where there was a small aperture through which the small quantity of blood in the bag of the pericardium had evidently escaped. The clot was hard and solid, and was fixed in its position, from its being completely entangled in the cellular tissue lying between the serous membrane and the outer coat of the arteries, and between these two vessels at the point where the pulmonary artery passes anterior to the aorta; in this spot the coagulum was thicker than in any other.

The coagulum occupied exclusively

all that space external to the vessels, and underneath the serous membrane; it passed downwards on the auricles to where they join the ventricles, and it also passed some way upwards, beneath that membrane which anatomists describe as descending from the deep layer of the cervical fascia, to become continuous with the fibrous layer of the pericardium.

In other respects the aorta was extensively diseased, being thickly coated from the commencement of its transverse portion, all along its descending course, with bony plates and atheromatous deposits. Indeed, the only part of the artery which appeared free from this disease was the very situation where the laceration took place; for immediately to the left of the opening there was another large osseous deposit. On comparing the middle and internal coats of the artery, at the seat of rupture, with other parts, they were found to possess scarcely half the thickness, and were much more friable, though the vessel did not present, in any part, traces of acute inflammation. Towards the commencement of the arch the vessel was somewhat dilated, but not to a greater extent than is ordinarily observed in individuals of her age.

The mouth of the innominate was filled with a dark and firm clot, which extended for some distance along this vessel and its two divisions, and appeared to have been produced by the mechanical pressure exercised on it by the clotted blood which lay between its outer and middle coats. The lungs and liver were greatly engorged, no doubt the result of the mechanical pressure exercised on the veins leading from them, and of the almost complete obliteration of the cavities of the auricles.

ON THE MEDICAL AGENCY OF WATER AT DIFFERENT TEMPERATURES.

By DR. WILKINSON, Bath.

(For the Medical Gazette.)

HISTORY informs us that in the most ancient periods ablutions were considered so conducive to health, as to constitute an important part of religious ceremonies; emblematical of

mental purity. Most probably the custom was first adopted in warm climates, and from the salubrious result became sanctioned and enjoined by many religious institutions: thus it was not only adopted in Mosaic and other ceremonies of worship, but also the early Christians, previous to partaking of the holy communion, purified themselves by ablutions with water.—

In a state of health every part of the animal frame has its determined laws of capacity for caloric and electricity; and in every local or general deviation a change in these active agents takes place. A restoration to health can only be contemporaneous with that state of organization the body originally possessed. In cases where caloric becomes morbidly liberated, in partial or general currents, practical medicine makes use of cold media, in a highly rational manner, to promote the required material change. This occurs during certain morbid conditions in the substance of the centre of the apparatus of motion in the body, when a glowing heat and a rapid current of blood towards the head point out an abnormal metamorphosis of the brain; and when this condition continues beyond a certain time, experience teaches that all motions in the body cease. In such extreme cases every practitioner knows that by surrounding the head with ice the temperature soon becomes lowered; and the ice should not be removed before the liberation of heat has accomplished the restoration of the natural temperature.

In my future observations I shall attempt to more minutely explain the powerful agency of the active imponderable principles—caloric and electricity—in various functions of the animal economy, at present confining my attention to the relative proportion of caloric, or the matter of heat in ice and water. It has been ascertained, that if any given weight of ice, at 32 degrees, be mixed with a corresponding weight of water at 172 degrees, the ice will be melted, and the resulting fluid mixture will be at 32—the water having lost 140 degrees, and the ice, during its conversion into water, having acquired this portion of heat. The same principle applies to the human body in every altered state of structure or arrangement. Caloric is either in excess or diminution, and its equalization

should be the first object of medical attention. Every person who has recourse to ablution, in a morning just after rising, well knows its beneficial effects: the cuticular surface is preserved in good order, and all irregularities as to temperature corrected. For the purpose of ablution, a convenient apparatus is made of tin or zinc, from 4 to 6 feet in diameter, and about 6 inches deep. In the centre the individual stands, and with a large sponge applies the water freely to every part of the body, which is afterwards to be well dried. The coarser the towel used the better: if the weather should be very cold, the temperature of the water may be a little increased; but the colder, the more powerful the reaction. An apparatus for ablution thus constructed can be conveniently introduced into a bedroom, with the advantage of its use on the moment of rising from bed, which is the best time for its employment, and the refreshing result is highly conducive to the preservation of health. In debilitated constitutions, when the action of the douche is found too powerful, then ablution constitutes an excellent substitute, gently rubbing all the parts particularly affected, and preparing, if required, for the subsequent application of moisture. When dressed, it is always well to drink about half-a-pint of cold water, and if weather permit to take a long walk before breakfast. By this process all that languor which results from excessive perspiration is most effectually removed.

In tropical countries it has long been the practice of professional gentlemen in febrile diseases to dash cold water over the patient, morning and evening; and particularly if the fever have a typhoid character, and is accompanied with a diminution of nervous energy. Dr. Currie most successfully introduced at Liverpool the affusion of cold water in the treatment of this species of fever. His mode of application was by pouring two or three quarts on the patient's head and body: he confined this practice principally to the low contagious fever, and selected the early stage of the greatest heat; but recommended water not to be applied when the patient was in a state of chilliness, even if the thermometer indicated a preternatural degree of heat, nor in a case of fever arising from or accompanied by topical inflammation. It is

greatly to be lamented that, from inconvenience attending affusion, or any supposed fatigue, this excellent mode of practice should be so rarely adopted, and particularly when so much benefit is quickly derived from it. In cases when the skin is hot and dry, or the pulse exceeding 120, the tongue parched and discoloured, how grateful to the feelings is the cold affusion: the heat of the body is rapidly diminished, the irritating dryness of the skin is removed, and the pulse reduced to that standard which allows of a quiet slumber and a gentle perspiration. Whenever the pulse exceeds 120, it may be generally concluded that its frequency is the result of constitutional debility; the reduced energy of the heart compensating for power by more frequent feeble pulsations. On the prevalence of this species of fever at the Foundling Hospital, my medical friend, Dr. Stanger, more than 40 years since employed, with the greatest success, this cold mode of treatment; and although by practitioners of eminence stimulant remedies were found highly pernicious, yet cordial and tonic medicines by many have been employed, combined with the opposing principle of abstraction of blood.

We have varying opinions relative to the agency of cold water in some neuralgic affections. Dr. Watson says that a tetanic patient in St. Thomas's Hospital, at his own desire, was plunged into a cold bath, and instantly died. Sir James Macgrigor observes, that during the campaign in Spain, the warm bath gave only momentary relief, and the cold bath was worse than useless. But Mr. Abernethy stated, that were he himself the subject of tetanus he would have the cold affusion tried.

SOME OBSERVATIONS
ON THE
MEDICAL TOPOGRAPHY, CLIMATE,
AND DISEASES,
OF THE
BIGHTS OF BENIN AND BIAFRA,
WEST COAST OF AFRICA.

BY W. F. DANIELL,
Member of the Royal College of Surgeons of
England, &c.
[Continued from p. 709.]

NOTWITHSTANDING the conflicting statements that have been promulgated

from time to time respecting the salubrity of several rivers and other places frequented by the white traders in this portion of Western Africa, the Rio Formosa will be found upon dispassionate inquiry to be the most unhealthy. The only streams in the Bights which resemble it in point of insalubrity are the Rio Nun and New Callabar; but the sacrifice of European life in them, although considerable, falls short of that observed in the Benue river. The constant prevalence of a class of insidious febrile diseases, (particularly remittent fevers,) whose adynamic type, rapid career, and other pathological features differing so greatly from those of other tropical climes, sufficiently stamp it with that odious celebrity now widely diffused and too justly merited. Our colonial settlements in the Gambia and Sierra Leone, from the severe ravages of occasional epidemics, have also been invested with a certain degree of ill fame; but they, if placed in comparison with the river I have been lately describing, would be deemed far more salubrious. It must, however, be borne in mind, that while these maritime districts are thus abundantly fraught with those influences which give rise to this unfavourable condition, their deleterious effects have been much augmented by a series of petty and vexatious annoyances to which all Europeans are subject who come within their sphere. The slimy mudbanks and alluvial swamps, it is well known, generate myriads of musquitoes and sandflies, and these insects so vigorously attack all who reside where they abound, as to prove exceedingly troublesome. In vain the wearied seaman seeks for repose; his winged tormentors multiply as the night advances, and, ever on the alert, incessantly hover around him, until he is at length forced to succumb to their harassing inflictions, and unwillingly hastens upon deck, there to await, in no happy mood, the break of morn. Heavy toil by day, with broken and unrefreshing slumbers, will soon undermine the strength of the most hardy; and hence it is that these, in conjunction with other apparently trivial causes, amply predispose the unseasoned stranger to the attacks of endemic typhoid affections, from which so few have as yet recovered. Barbot, in allusion to this subject, truly re-

marks, "that the lands on each side of the river are very woody, which breeds those tormenting vermin in such immense numbers, that they attack our sailors at night on all sides, and so pester them, that many the next morning are not to be known by their features, depriving them at the same time of their natural rest, which, together with the unwholesome air, occasions a great mortality among our Europeans, some sloops or ships in one voyage often losing one-half of their crews, and others more, and the survivors remaining very weak and sickly, which strikes such a terror into sailors that few are willing to serve in such voyages, and the boldest always afraid of their lives*."

When I visited this river in 1839, I found two vessels moored a short distance from its mouth, one of which, within the space of five months, had buried two entire crews, a solitary person alone surviving; the other, which had entered at a much later period, had been similarly deprived of one-half of its men, and the remainder were in such a debilitated condition as to be incapable of undertaking any active or laborious duty. Another vessel sailed from this port, previously to my arrival, in such a deplorable state as to be solely dependent on the aid of Kroomen to perform the voyage homewards. After a stay of several weeks at the anchorage opposite Jacqua creek, the ship to which I was attached became so unhealthy that we were under the necessity of recrossing the bar into a purer atmosphere, having lost one-third out of a complement of eighteen men. And yet, amid these regions so rife with disease and death, I have known Europeans reside for a number of years in the enjoyment of good health, from the simple secret of moderately conforming to the habits of the natives as regards the diet, exercise, and attention to the due performance of the cutaneous functions. The plan of treatment I then pursued in the cases of fever which came under my care, was local and general blood-letting, saline purgatives, calomel in large doses, &c.; in fact, that treatment sanctioned by the most experienced writers on tropical diseases of a similar nature. I regret to state that in these, as in numerous

* Description of the Coasts of North and South Guinea, book iv. p. 319.

other instances, this system of treatment was evidently one which possessed no power of controlling the progress of the remittent fevers of inter-tropical Africa.

Perhaps in no part of the African continent is the medical profession held in higher estimation than by the negro tribes of the kingdoms near the sea-coast. In most of the rivers of the Bights the medical officer, if he were so inclined, could easily convert his ship into a lazarette, from the influx of patients that would voluntarily place themselves under his sanitary regulations. Natives of every rank express the greatest confidence in his skill, and the efficacy of those remedial measures exhibited for their benefit; and should such unfortunately fail of affording the desired relief, the case is considered by them as hopeless. Whenever, therefore, the surgeon of any vessel is known to be somewhat liberal in the distribution of his medicines, innumerable invalids flock on board, and, without hesitation supplicate his attention to their real or imaginary complaints; and many urge their claims so cogently that it requires no small amount of patience and firmness to withstand their importunity. Medical science in Soudan, and other inland countries, is also fully viewed in the same favourable light; and the white practitioner, if the assertions of travellers are to be credited, is considerably treated with kindness and hospitality. Clapperton pays an honourable tribute to its utility and value when he states, in the following passage, "that the news of our arrival spread before us, and at the different towns and villages through which we passed they brought us all the sick to be cured. Nor was it the sick alone who sought advice, but men and women of all descriptions; the former for some remedy against impotency, the latter to remove sterility. Many came for preventives against apprehended or barely possible calamities; and, in anticipation of all the imaginary ills of life, resorted to us in full confidence of our being able to ward them off." By the population of some countries the sources of disease are attributed to supernatural agency. In Warree, an evil principle, designated by the term Mallakew, is supposed to live in the

waters of the river, and to afflict all who have not paid a proper deference to his power by appropriate propitiations. Fowls, sheep, &c., and sometimes human beings, are immolated for this purpose.

Fourteen miles S.E. by S. from Beniu river, is the Rio Esclavos, or Slaves' river, known also in native parlance by the name of El Broder, or Brodero. It is considerably inferior to the Formosa in magnitude, but like it is obstructed by a bank of sand that debars access to any but vessels of light tonnage. Adjoining its entrance, is a small town, erected on the margin of a sandy beach, and which is encompassed and partially hid from view by a profusion of palm and cocoa-nut trees. The Rio dos Forcados, or Galley Slaves' river, usually termed the river Owerree, or Warree, is fifteen miles further to the southward. Both this and the Esclavos, from their shallow estuaries, are seldom or never frequented, unless it be by slave-ships, although in the seventeenth and eighteenth centuries the Portuguese and Dutch carried on a lucrative commerce with them, especially the latter. At the distance of three miles from the entrance is the island and town of Paloma, the latter consisting of from twenty to thirty dilapidated houses, situated on the left bank of the stream. The inhabitants transmit what little palm oil they produce to Jachree; the majority of them in are now fishermen, and chiefly occupied the curing of fish. Formerly the Portuguese had a fort, chapel, and three or four factories, in this town; but they were soon abandoned on account of the extreme insalubrity of the climate. Jerome Merolla da Sorrento, in his voyage to the Congo, informs us that two Capuchin missionaries, named B. di Firenze and A. Avaccio, sailed from the Island of St. Thomas, in 1683, to visit the metropolitan town of Warree, which by this route is about sixteen miles to the north-east of Paloma. They were the first persons that attempted to introduce Christianity into equatorial Africa, and, it has been stated, converted many of the natives to its doctrines. The people of this and the circumjacent countries were called by the ancients Derbiei Ethiopes.

The Rio Ramos, or Bough river, is seventeen miles to the northward of that of Warree, and the river Dodo

* Journey from Kouka to Murnur, p. 23.

twenty miles E. by S. from the R. Ramos. Neither of these streams are visited, except by contraband schooners for human cargoes, and to elude the vigilance of the men-of-war cruising without. Thirty miles south-east from the Dodo is the river Sengana, or Segma, at the aperture of which may be distinguished several isolated groups of mud habitations. The land here is very low and marshy, and the inhabitants are such a degenerate race, that they appear in physical conformation to be but a few degrees removed from the higher animals of the Simiæ family. None of these rivers offer any inducement for the white trader to enter them, and are alike inimical to his health and safety. An insignificant point may be noticed a few miles to the northward of the Sengana, which has been commonly, but erroneously, named Cape Formosa. It is in $4^{\circ} 31' N. Lat.$, and $5^{\circ} 41' E. Long.$ The river Sengana is the southern extremity of the Bight of Benin, and the obvious projection of the land in its vicinity may therefore be termed, with more propriety, the cape. This Bight comprises a tract of coast of nearly 360 miles in extent, and, excluding some parts of the Slave coast, may be merely considered as one vast and almost interminable forest swamp, whose continuity is broken by the petty rivers and creeks that meander in all directions through it. It is without exception the most deadly portion of the West coast of Africa.

[To be continued.]

ANALYSES AND NOTICES OF BOOKS.

"L'auteur se tue à allonger ce que le lecteur se tue à abrégé."—D'ALEMBERT.

The Chemistry of Vegetable and Animal Physiology. By J. D. MULDER, Professor of Chemistry in the University of Utrecht. Translated from the Dutch, by Dr. FROMBERG, First Assistant in the Laboratory of the Agricultural Chemistry of Scotland. With an Introduction and Notes, by JAMES W. JOHNSTON, F.R.SS. L. and E. Part I.

HERE is a book of much promise upon a very difficult and important object, written by a very distinguished investigator of organic nature, and translated under the auspices of an able

English chemist; and yet with all these advantages it will give little satisfaction, so far as it has proceeded, to the practical-minded men of this island. The introduction is not prefixed by Dr. Johnston, as he had intended, but is withheld till the whole original work shall have come into his hands. Of the part published, containing 184 pages, the first 85 are occupied chiefly with hazy metaphysical reveries, which lead, as far as we can guess, to no useful applications, whether in chemistry, physiology, or agriculture. The very first opening of his subject reveals his tendency to the transcendental.

"In the doctrine of life, no position has been more strenuously maintained, than that a peculiar force exists by which organic substances are governed, by which they are arranged in certain specific modes, and are enabled to assist in sustaining the living system, and to create a chain of phenomena which as a whole are called *phenomena of life*. This vital force has been described as one quite peculiar, of which not the slightest trace is to be found in inorganic nature. Organic and inorganic nature are often indeed contrasted. We hear of the animate and inanimate forces of nature; we used to shrink from observing any connection between them; and, in particular, it was thought that the endeavour to explain many phenomena of life by means of the so-called dead forces might detract from the doctrine of life.

"In the true study of nature the principal aim ought to be, not only to make ourselves acquainted with the phenomena and laws, which distinguish and regulate living and dead matter, but also to arrange those phenomena and laws, and exhibit them in their several relations. The more our knowledge of these two departments is extended, and the nearer the several parts of the great science of nature are seen to approximate, the more firmly must we embrace the idea, as necessarily conformable to truth, that the same forces govern alike the animate and the inanimate kingdoms.

"Those who proceed on the assumption, that no such connection exists, will certainly not be able to trace it; but a search, conducted with impartiality, will be rewarded with the discovery of as much as may exist.

"In the natural sciences, the words *matter* and *force* are continually recurring. We endeavour, by an effort of imagination, to separate the one idea from the other. Yet we cannot conceive of matter without force, and scarcely of any force which does not react upon matter. We encounter many difficulties, while attempting to penetrate into the properties of matter. We are perplexed, first, with its being divisible either finitely or infinitely; secondly, with the great diversity of substances which exist; thirdly, with the great number of elementary bodies now known to chemists."

In the country of the modest Newton, we have been taught to believe that researches, however *impartially* conducted, may not be rewarded with the discovery of as much as may exist; nay, that the *ultimatum* of existing truths may never be reached by our finite faculties. We have always been accustomed to regard *inertia* as the characteristic of matter, and that all forces, and most manifestly the vital, were foreign to, and superinduced upon it. We think it an utterly unauthorized dogma, that the same forces govern the animate and the inanimate kingdoms.

Our author's style of general philosophical reasoning may be fairly appreciated from the section D, p. 78, entitled "*Transference of Vital Force*."

"The idea of transferring vital force is opposed to the idea of force. A slumbering force is awakened; a weak force is strengthened; but it is impossible to imagine the transference of a force from one material mass to another. We must first refer to this point in pausing to consider the manner in which we must conceive of the transition, into a new organic whole, of life originating in another. If animals impart vital forces to their offspring, then such forces must, no doubt, be lost by themselves. We do not perceive, however, that this takes place; on the contrary, they retain their strength, sometimes for many years, after having produced new beings, completely formed, of the same species. The tree which, for a great many years, produces fruit, and the seeds of which have, in great numbers, become full-grown trees around the parent stem, nevertheless lives as at first. A single poppy plant produces

thousands of small seeds, each of which grows up to a poppy plant equally perfect. Hence we are not entitled to admit the idea of transference of vital force, even where it is not opposed to the idea of force itself. With our own eyes we perceive the evolution of that force from its phenomena.

"What part, then, bears the germ of that vital force, which is afterwards to be developed? and at what point does the development commence? It is the poppy seed which bears the germ,—a small quantity of organic molecules, different in nature from all others,—some carbon, hydrogen, nitrogen, and oxygen, combined in a certain manner into substances, which are peculiar in respect of their composition and arrangement. The peculiar quality which distinguishes these substances from amorphous precipitates and crystals, they owe to their origin. Their elements were brought into a state of peculiar tendency, by the forces residing in the organic molecules of the plant, whose influence had previously governed them. They do not possess more than they exhibit, and they exhibit nothing but a change of their chemical composition. The seed changes its starch into gum and sugar, and so chemical forces forthwith appear, which seem to be intimately connected with the development of new forms. Another phenomenon soon succeeds, namely, the absorption of substances from without. These bring something with them: they are not merely *substances*, but the residence also of peculiar active forces to which they owe their composition. Of these forces, some portions combine with those which are derived from the seed itself. And now, the previously existing molecule, and that which is formed from external matter, both live;—the former through what it received from the parent-plant,—the latter through its having assumed the form of the other. This conformity arises from matter, and from the property which matter possesses, of obeying the action of forces, proceeding from the first molecule; in other words, the second molecule must necessarily be endowed with the capacity of becoming similar to the first, through the influence of the first. Thus, the second molecule did not receive its peculiarities, but

these were excited in it; and so this molecule also lives as well as the first, and in its turn can take up new substances from without, and entirely assimilate them. So again, the third lives also, and thus is life gradually extended. The molecules, after being once arranged in a certain manner, give birth to new arrangements, to new forces, as we endeavoured before to explain."—Twaddle.

In the second chapter on inorganic, organic, and organised bodies, plants, and animals, we find nothing definite and interesting; but in the third chapter, on the Atmosphere in its connection with organic nature, there are some curious enough lucubrations. After compiling from well known sources all the experiments upon the proportion of oxygen and carbonic acid gas to azote in the atmosphere, he comes to the following conclusion.

"It is not to be denied, that the quantity of carbonic acid must have become greater, and that of oxygen less, with the increase in the numbers of men, who respire, and make fires, and whose dead bodies putrefy;—but, on the other hand, a great many animals, on the increase of mankind, have been expelled from the earth's surface. By the fires, however, which man has kindled, the quantity of carbonic acid has undoubtedly been increased, and that of oxygen diminished; but it is difficult to decide with certainty whether that increase in the carbonic acid would have ever become perceptible, even though the very first human beings had been able to make eudiometrical experiments. It is, however, probable, that in any given bulk of atmospheric air, they would have found a little more oxygen, and somewhat less carbonic acid, than in the present day, provided the method of investigation had been sufficiently accurate.

"It is a consequence equally undeniable, that either the atmosphere will at last become infected by man, or that famine will arise on the earth. By the continual increase of man on the earth, the number of forests has been diminished. Man expels and destroys animals and plants, which previously lived undisturbed. It is principally by the large forests that the great quantity of carbonic acid, resulting from combustion and respiration, must be decomposed. There must necessarily be a

proportion between the number of plants and that of man and animals on the earth. The former must restore what the latter have taken from the atmosphere; the one must decompose what the other has imparted to the atmosphere. Wherever the equilibrium between the number of plants and animals is disturbed,—that is, when mankind increase and plants diminish,—then there will at last be no longer a sufficient quantity of carbonic acid decomposed, and the proportion between the oxygen and nitrogen, which we now assume to be invariable, will be altered.

"It is true that a large portion of the earth, susceptible of cultivation, still remains uninhabited by man. But if, in imagination, we transfer ourselves into futurity,—if we suppose the woods destroyed, the earth covered with edible plants which reach but to a small height in the atmosphere,—then we have in imagination reached a limit to the invariableness of the existing composition of the atmosphere, and at the same time to the existence of man upon our planet. The disappearance of the falls of Niagara and that of the human race belong to periods, which, it may be, are still far distant, but which, notwithstanding, will certainly arrive, if nothing meanwhile interpose.

"When will that period arrive? This is a question to which we may give an approximate answer. According to the experiments of Lavoisier and Davy, a man consumes 26·04 Paris cubic feet of oxygen in 24 hours; that is, 9,505 cubic feet a year. Let us suppose the number of men on the earth 1,000 millions, then these consume 9,505,000,000,000 cubic feet of oxygen every year, that is, nearly 8-10ths of a cubic geographical mile. The whole amount of oxygen, by which the earth is surrounded, is 1,953,570 cubic geographical miles. So that, if the number of mankind on the earth were always 1000 millions, they would require 2,451,000 years to take away all the oxygen from the atmosphere. If, from the present moment, plants were to cease decomposing carbonic acid, all the oxygen of the atmosphere would be exhausted after 2½ millions of years.

"By the operation of this cause, therefore, the human race will at some time be destroyed, if it should not happen to be so previously from other causes."

The fourth chapter treats of water in its connection with organic nature; the fifth, of the relation of the soil to organic nature. Here at last the author is at home, and becomes practically instructive. The remaining 53 pages of the book are interesting from the detail of valuable facts which they present, upon the varying composition of soils as derived from different geological rocky formations, and on the organic constituents of soils, such as crenic acid, apocrenic acid, geic acid, humic acid and humin, ulmic acid and ulmin; for the chemical properties of which seven bodies, we must refer to the book itself. The subsequent portion of the work will undoubtedly prove much preferable to the present; which abounds in vague and shadowy generalizations.

Human Magnetism; its Claims to Dispassionate Inquiry: being an attempt to show the Utility of its Application for the Relief of Human Suffering.
By W. NEWHAM, Esq. M.R.S.L.
London, 1845, pp. 432. Churchill.

WHILE we confess our utter inability to believe that animal magnetism is anything more than a creature of the fancy, we do not pretend to set bounds to the effects which may be thereby produced upon weak and credulous mortals. Imagination we are persuaded often exercises marvellous power in controlling disease, be it of body or mind. Hence the reputed efficacy under peculiar circumstances of metallic tractors, homœopathic globules, galvanic rings, and the like.

According to our author, "magnetism may be said to be the medicine of nature—to consist in the communication of the exuberant life of the healthy, to repair and sustain the deficient vitality of the sick,—and is *only* legitimately and justly used, when employed to restore that equilibrium of health, which has been restored by malady."—p. 17.

If this be its real definition, what an ample field for good is laid open in our workhouses. Let the pale, sickly, emaciated inmates be put without delay *en rapport* with a set of lusty yeomen, "whose limbs were made in England." The *vis vivida vite* thus imparted cannot but exercise a most salutary influence.

The author repudiates the idea of

magnetism being either supernatural or connected with satanic agency; laments the opposition of medical men to its doctrines; discusses the objections which have been arrayed against it, its applicability to the relief of medical and surgical diseases, and the requisite qualifications to practise. He concludes with the consideration of somnambulism, clairvoyance, prévision, phreno-magnetism, and extase. Some extracts from Miss Martineau's statements are inserted by way of appendix.

In the dedication, addressed to a reverend young friend, the author alludes to extracting "the sting from one page of suffering humanity." This rather posed us at the outset; for although we once read in some eastern tale of a book with poisoned leaves, we never before heard of a page with a sting. We are led to think the writer a well-meaning man, and only regret he should have allowed himself to plunge headlong into the depths of unauthorized and futile speculation.

MEDICAL GAZETTE.

Friday, March 14, 1845.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medice* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

THE IMPROPER ADMINISTRATION OF MEDICINES.

It is a somewhat startling fact, as set forth in the Sixth Annual Report of the Registrar-General, in the abstract of the causes of death by violence for 1840 (exclusive of ascertained suicides), and under the head of chemical injuries, that eight persons died from opium, twenty-one by other poisons, and no less than five by "medicines improperly given." Thus nearly fifteen in the hundred of individuals reckoned to be destroyed by poisoning fell victims to the improper administration of physic. This circumstance surely bespeaks the urgent necessity for putting a stop to the indiscriminate sale of

apothecaries' were now permitted. We earnestly hope, for the sake of the community at large, that Government will provide against this evil, either directly by legislative enactment, or indirectly through the medium of the Council of Health. In France, grocers, druggists, and apothecaries, come within the jurisdiction of the *Conseil de Salubrité*—a sanitary body in connexion with the police, and over which that important functionary, the prefect, always presides. His assessors are twelve titular members, six adjunct, and an indeterminate number of honorary members. The dean of faculty in the School of Medicine, together with the professors of public hygiene, and of medical jurisprudence, are members in right of office. This council is called upon to decide all questions respecting the health of the public, including the proper measures to be enforced on the outbreak of epidemic, epizootic, and contagious diseases; the due observance of the laws regarding burials; the prevention of nuisance, and of the sale of spoiled, debased, or noxious drugs.

It is to the last point we crave special attention, namely, that France, with a well organized school of pharmacy, deems it expedient to place all practitioners of that art under the vigilant supervision of the Council of Health. We can perceive no valid reason why the procedure of a country so justly pre-eminent in matters of science should not be adopted here.

A most flagrant instance of the fatal effects of nefarious physicking was divulged on a recent trial at the Cumberland Assizes. A man was indicted for causing the death of another, by administering to him three grains of corrosive sublimate and thirty grains of jalap. It came out in evidence that the prisoner, who went by the name of the "old soldier," was in the habit of dealing in medicines. To the unfortun-

nate deceased he gave two brown powders, into each of which he had been seen to put, with the point of a pair of scissors, certain tiny white lumps from a packet contained in a spectacle case; two small pieces into one powder, and one large one into the other. The largest was about half the size of a wheat corn; the others about that of a pin's head. A druggist's apprentice deposed to having sold the prisoner a pennyworth of jalap, which might have been two scruples; he did not weigh it—some drugs are thus disposed of—this he "sold at a guess."

Soon after swallowing one of the doses, the poor fellow was seized with vomiting, great difficulty of breathing, pain and burning from his throat to the stomach, under which symptoms he shortly died. On cadaveric inspection, the lining membrane of the stomach was found in a state of gangrene; the presence of corrosive sublimate was distinctly ascertained in that viscus.

The prisoner applied to a professional man, about a quarter of a year previously, for sixpenceworth of sublimate, but was refused. To a labouring man he had sold a recipe for a shilling, directing him at the same time to take about half a wheat-corn of "*crow's supplement*." He was found guilty, with a recommendation to mercy, and sentenced to be imprisoned during four calendar months, with hard labour.

It was not stated where he obtained the deleterious ingredient; but one thing is clear, that articles of that sort are much too readily procured in this country. Chemists, moreover, are blameworthy who allow their apprentices to dole out physic by guess.

Now we ask, even granting the force of the Roman adage, *agrotus debet sibi imputare cur talem elegerit*, are the public to be left at the mercy of such ruthless miscreants? At present there

is nothing to prevent this, or to check their unhallowed traffic. If a man chooses to take the title or addition of "old soldier," and to doctor people, he will be able to do so with impunity. He will infringe no law. The act does not come within the purview of the well-drawn restrictive clause of the new bill. It is only when convicted of manslaughter, in a court of assize, that he is liable to punishment. We would therefore suggest the following remedy. Let it be made illegal for any individual to deal in medicines for gain who is not duly qualified. Let, as we have repeatedly inculcated, every practitioner in pharmacy be examined, licensed, and registered by a board authorized by the Council of Health, and let him be strictly confined to the duties of his calling—the preparing, compounding, and dispensing of drugs. Were such means adopted, we do not hesitate to say there would be far fewer instances of death on record from medicines improperly given. It is not our object to impugn the chemists, many of whom we know to be possessed of skill and intelligence, but to remonstrate against the ill-regulated condition of the practice of pharmacy in Great Britain, and the facilities offered to base and unprincipled persons for obtaining the most baneful drugs. The chemists, indeed, are well aware of the risk of danger from the latter circumstance, and certain of their number in Lancashire have printed and circulated some very judicious resolutions, which ought, in our opinion, to be generally enforced. They are as follows:—

"That no druggist shall sell any poison without putting upon it a printed label, viz. 'Caution: the contents of this is Poison;' also the address of the party selling must be upon the label.

"That no poison shall be sold to young children.

"That each druggist shall keep a book for the purpose of *registering* the

sale of arsenic and other deadly poisons. This book to have ruled columns, properly headed (in print), stating the kind of poison sold, the date of such sale, the purpose, or specified purpose, for which it was sold, the signature of the party selling, and, lastly, *the address and signature of the party buying the poison.*"

NEW CHARTER OF THE COLLEGE OF PHYSICIANS.

(From the *British and Foreign Medical Review* for April 1845.)

To the Editor of the *Medical Gazette*.

SIR,

THE accompanying paper cannot appear in its proper place before the 1st of April; may I hope that the importance of its subject will obtain for it the advantage of earlier publicity in the pages of your journal?—I am, sir,

Your obedient servant,

JOHN FORBES.

March 12, 1845.

A Bill for enabling Her Majesty to grant New Charters to certain Colleges of Physicians and Surgeons. Ordered to be printed 25th February, 1845.

THIS Bill enables Her Majesty to grant new charters to the Colleges of Physicians of London, Edinburgh, and Dublin, and to the College of Surgeons of Edinburgh. It gives no information as to the character of the charters to be granted; and as none of these have been as yet laid before parliament, the profession generally must, for a time, remain ignorant of their respective provisions. The only one of the intended charters, of the contents of which we possess any knowledge, is that of the College of Physicians of London; and it is with great concern—we may indeed say, as a member of that body—it is with no slight feeling of shame that we announce to our brethren beyond the pale of the college that it contains one most important clause, which, in our humble opinion, not only vitiates all that is good in it (and it contains much that is good), but stamps it, as a charter, in the highest degree as illiberal and unjust, alike unsuited to the spirit of the present time, and unworthy of the institution whence it emanates. The provision to which we refer is *the limitation of the fellowship to a small number of the members of the corporation*. At the moment

* *Pharmaceutical Journal and Transactions* for March 1845, p. 416.

we are writing, it is not finally decided whether the number of FELLOWS shall be definitely limited to *two hundred*, or shall bear a fixed proportion to the varying number of Licentiates or Associates. But, in either case, the result will be the same, viz. that *only a small proportion of the MEMBERS* (one-fourth, one-fifth, or one-sixth) *can by possibility become FELLOWS*, that is to say, *can obtain any corporate privileges, or attain any of the offices or honours of the College.* When it is considered that by the new charter the College is reconstituted as a CORPORATION—that its title is changed to that of the ROYAL COLLEGE OF PHYSICIANS IN ENGLAND—that by the new Bill every future English physician is *compelled* to join the corporation as a *member*, and to pay a fee on joining it; and yet that the obtaining of any corporate privileges, or attaining any corporate honours, can only, by possibility, fall to the lot of a small minority—it can hardly be imagined that such a constitution could have been framed at the present day by the members of a scientific body, or, if framed, that it could obtain the sanction of the government. That it has been framed, however, is certain; but we are far from believing that it will obtain the sanction of government without modification.

The charter recently granted to the COLLEGE OF SURGEONS, and which has excited so much discontent in that branch of the profession, is greatly more liberal and just than the one under consideration; inasmuch as, by the Surgeons' charter, *every member may become a FELLOW*, and thus attain all corporate rights and privileges, on submitting to certain conditions therein laid down. It remains to be seen in what light the Physicians will regard the charter about to be granted to their College; but if, on being made aware of its character, they sit down in quiet and silent contempt, we shall, to say no more, be surprised. The College, however, in such a case, may be justified in considering its proceedings as sanctioned by those most affected by them; and, though we will not the less maintain the justness of our own views, we will at once admit that we have been mistaken as to the opinions and feelings of the physicians of England.

Instead of stating, as we have done, that the future Members or Associates of the College of Physicians possess by the charter *no corporate rights or privileges*, we ought to have stated that *one privilege is conceded*, which the College may possibly regard as of some value: as, however, we consider it the reverse of valuable, we have rejected it from our category of corporate rights. The privilege is this:—The members are permitted, on one day in the year, to meet the Fellows in the College, and to vote, *in con-*

junction with them, in the election of Fellows (four or five, perhaps) to fill up the few vacancies occasioned by death! For ourselves, we confess that we hope never to see a spectacle so melancholy—to use no harsher term—as that of a body of gentlemen thus consenting to compromise at once their dignity and their rights, by sanctioning an act of injustice towards the whole body of which they are members, and thus assisting in their own degradation.

In making these observations, we consider ourselves as discharging an imperative duty towards the College of Physicians. Considering the provision of the charter here animadverted on as calculated to be still more injurious to the College than to the profession, we feel that we should not be fulfilling the solemn obligation we came under on becoming one of its members, if we failed to advocate any measures which we deem calculated to promote its best interests. The voice of the profession, if it chooses to speak, may be listened to, though our words may have been unheeded; while its silence, if it remains silent, will at least save the College from the annoyance of any more fruitless discussions within its own walls.

IMPORTANCE OF CHEMISTRY.

FOR the proper study of the functions performed both by plants and animals, a knowledge of chemistry is essential, and it has therefore long formed one of the objects of professional study. Without it we should be ignorant of the intimate nature of the products of animals, either in health or in disease, and be unable to understand the phenomena of several of the functions of the body, or the changes which take place in them in disease. We require a knowledge of chemistry for the preparation of drugs; also for understanding the principles which require to be attended to, in their prescription and administration. Animal chemistry, also, by informing us accurately of the changes which take place in many of the secretions in disease, will no doubt lead to great improvements in practice."—*Medical Education; being a Lecture delivered at King's College by J. Forbes Royle, M.D.*

FACULTY OF GLASGOW.

To the Editor of the Medical Gazette.

SIR,

HAVING been for many years a member of the Faculty of Glasgow, I read with much interest your remarks on the summary proposal to ~~extinguish~~ this ancient Corporation.

Truly, the change between the present bill and its predecessor argues a despotic tendency which one does not expect to witness now-a-days on the part of our lawgivers. Sir James Graham is very accommodating in certain quarters. The English corporations are to be thoroughly respected—the universities won't permit their privileges to be tampered with in the slightest degree. The vested rights of the Apothecaries' Company are to be maintained, although not of thirty years' standing, whilst the corporation of Glasgow, founded by Royal Charter more than two centuries ago, must be swept out of the way, because it has been found inconvenient to certain other institutions! I trust, however, that the ruling powers of the Faculty will bestir themselves, and look after the interests of themselves and the members at large. Sir James appears to lend an open ear to every body, and the last advisers are ever the most welcome.

Seriously, I would ask, Mr. Editor, what will be the position of members of this corporation if this iniquitous proposal be carried? Being no longer members of any collegiate body, are they to be cast out of the ranks of the profession? What necessity exists for such a change as the threatened one, I cannot conceive, but if some alteration be essential, then I would suggest that the Edinburgh and Glasgow Colleges be united under the title of the Royal College of Surgeons of Scotland, each having its due share of power and influence in the new incorporation. Some such arrangement as this is (at least) due to the Glasgow College, and is more especially due to its present members, who have taken out its diploma on the faith of the stability of its chartered rights.

Thanking you, Mr. Editor, for your able advocacy of the rights of this ancient body, I subscribe myself, sir,

Your very obedient servant,

A MEMBER OF THE FACULTY.

March 8, 1845.

THERMOMETRICAL REGISTERS.

To the Editor of the Medical Gazette.

SIR,

I AM induced to trespass on your attention in consequence of two communications inserted in the GAZETTE of the 7th ult. and the 8th inst., the utility of which, to the generality of your readers, I am at a loss to discover. It would be unreasonable to expect that medical men in general should keep a meteorological register so scientific as the one kept at Greenwich Observatory; still we might hope for something more

practically useful than those forwarded you by your correspondent C. from Torquay.

A register of observations made at 9 A.M. and 9 P.M. as regards the barometrical, thermometrical, and hygrometrical state of the atmosphere, with the general direction of the wind, and character of the day, would, in my opinion, be extremely desirable, as affording the means of tracing something like cause and effect between the climate and the diseases which prevail at various periods, and hence enabling us with more confidence to suggest means of prevention, and, as far as it may indicate the probable nature of disease, a more beneficial mode of treatment. But, at the least, such reports, drawn up from observations made on the same plan, and with instruments similarly placed, would be sufficient to enable the profession to arrive at a tolerable estimate of the relative climate of the different localities where such registers might be kept, and thus afford them the opportunity, in cases where change of residence is desirable, of selecting a situation with rather more certainty of its being beneficial, than has hitherto been the case. Of course, the geological character, aspect, and bearings, of each place, should be described at the outset.

I am aware that, in the quarterly reports of the Registrar-General, some meteorological reports are published, and my object in addressing you is to endeavour to excite the members of the profession generally to take up the subject, and that your correspondent at Torquay may be induced to extend his observations, and make them more worthy the pages of your valuable journal.

I am, sir,

Your obedient servant,

AN OBLIGED AND CONSTANT READER.
Dover, March 10, 1845.

OPIUM A HAZARDOUS REMEDY IN STRANGULATED HERNIA.

THE following cases were related to the New York Medical and Surgical Society, with a view to shew the danger of using opium or its preparations when strangulation of a hernia is suspected; the symptoms of strangulation being masked by the medicine, and the operation consequently being deferred until too late to be successful.

Dr. Buck stated that he was called to operate on a lady aged 60, whose hernia (femoral) had been strangulated two days. She had been put under the influence of tobacco and an anodyne injection, administered on the first day she was taken ill, which was Sunday. On Monday she was found in a state of profound narcotism. On Tuesday Dr. Buck was called in. The patient then

lay in a stupor, and did not appear to suffer. The hernial tumor was large, and its contents were omentum and intestine. The operation was performed the same day, and death ensued thirty-six hours thereafter. On examination, the strangulated portion of intestine was found of a purplish brown colour.

Dr. Watson reported as follows :—a lady, aged 64, a rather small and spare woman, about six weeks before the present attack, was seized with severe and sudden pain in the bowels, which was considered bilious colic. She was treated with very large and repeated doses of opium, which for the time overcame the pain. On Tuesday, May 28th, while busying herself about her household duties, she was again taken as before, and the former treatment resorted to. The amount of opium was very great, some ten or twelve grains per diem for several successive days. The pain was effectually overcome, and the only evidence of a narcotism produced was a pleasant hallucination without sleep, and a tingling or itching sensation over the whole body. She continued under treatment in this way up to the evening of May 31st; and as a small swelling had recently been detected in the right groin, and her bowels had not been opened for nearly three days and a half, a consultation was requested. Dr. W. now saw her for the first time, about nine or ten o'clock at night, and recommended the operation. Some hesitancy existing, Dr. Mott also met the other attendants in consultation at midnight. The operation was resolved upon, and was performed by Dr. Watson. The hernia was femoral; no fluid existed in the sac.

The protrusion was small, and the parts united by adventitious adhesions, the result of inflammation, probably existing there since her first attack, some six weeks before. On the next day the narcotic condition still existed; bowels still constipated, notwithstanding the use of oil and enemata. On June 2d, the bowels were freely and spontaneously moved for the first time. After this, all evidence of narcotism subsided, and the case began to promise well. The wound was dressed on the sixth day, and it was then dry, and appeared to have united by the first intention; but in a day or two afterwards it opened, and gave issue to a very offensive discharge, which excoeriated the surrounding parts. The whole of the pubic region and the right groin became inflamed, and the discharge for several days appeared to increase in quantity, and become more offensive. On the 8th June, a large slough was found lying under the integuments in the bottom of the wound, which was removed. Portions of feces appeared on the dressings. The wound gradually contracted,

and she continued under treatment until July 15th, when a truss was applied.

Another instance was mentioned by Dr. Watson. The husband of a female aged 60 objected to the performance of the operation on his wife, and in consequence it was deferred from hour to hour. Sixty drops of laudanum were given to allay irritation, and a consultation called. Croton oil was prescribed to relieve the bowels. At the next meeting the patient was so comfortable and free from pain, that the operation was deferred until the next morning, when she was found moribund, being twenty-four hours from the occurrence of the strangulation.—*N. Y. Journ. of Med.*; and *Amer. Journ. of the Med. Sciences.*

EXTRAORDINARY EFFECTS OF A STROKE OF LIGHTNING.

By JOHN LE CONTE, M. D.

FIVE negroes were simultaneously prostrated by a single stroke of lightning on a plantation in Georgia. The sun was shining brilliantly at the time, and a greater portion of the visible hemisphere presented the usual serenity of the summer sky. A singular and rather angry-looking cloud had, for a short time previously, been observed near the verge of the south-eastern horizon, from which occasionally proceeded the low rumblings of very distant thunder. Suddenly the whole atmosphere was illumined by a flash, succeeded by a single report, and the cloud quickly dispersed, precipitating a little rain. The five negroes were all taken up in a state of apparent death.

"CASE I.—A negro girl, Adeline, aged about thirteen years, was up in the branches of a small mulberry-tree, twenty feet high, and standing sixteen feet in front of a line of negro houses, which extended parallel to a wood situated one hundred yards in the rear of the same. She was engaged in throwing down the fruit for her little companion below. Every principle of life seems to have been instantly extinguished by the intensity of the electrical shock :—her body had to be taken down from the branches of the tree where it had lodged. No marks of external injury observed.

"CASE II.—Another female child, Kitty, aged about six years, was standing immediately under the tree. She was instantaneously killed. No superficial marks of injury observed.

"CASE III.—Chloe, an adult woman, aged forty years, was walking about ten feet more remote from the base of the tree than the latter child; and, also, about five feet more distant than the two who survived the

shock, viz. than Cases IV. and V. She was instantly killed. No marks of injury recognised, excepting a burnt spot, the size of a dollar, under the right axilla. Her clothes were set on fire; but this was probably occasioned by the breaking of a tobacco pipe which she was smoking at the time, and which scattered the ignited contents over her cotton garments. In the three cases above mentioned all the ordinary attainable means of resuscitation were tried without success.

"CASE IV.—Charlotte, an adult woman, aged twenty-nine years, was standing halfway between Cases II. and III., and, consequently, about five feet from the root of the tree. After remaining in a state of insensibility for some time, she gradually recovered her consciousness. A dose of castor-oil was then administered. The skin on her right shoulder was abraded for a space as large as a dollar. Her clothes were rent into shreds; on the right side of her body, the skin was blistered, and marked with discoloured streaks, which extended anteriorly on the lower portion of the abdomen towards the pubes. A small streak likewise extended along the interior aspect of the right arm. She complained of pain in the stomach and bowels for three weeks. No vomiting or burning in the hands and feet, as was experienced in the next case. She has been married several years, but has never been pregnant. Her menstruation was perfectly regular prior to the reception of the shock, but has since that time been very irregular; sometimes having two periods per month, and then escaping two months. The flow has also been much diminished in quantity. Her health has not been very good since she was struck; manifestly resulting from her menstrual irregularity. A recent copious bleeding has afforded her evident and immediate relief. Her reproductive functions appear to continue dormant.

"CASE V.—Sarah, a woman aged at least seventy years, was standing immediately beside the last. She, likewise, gradually recovered her consciousness. No medicine was administered. Her clothes were rent; and after a few days, marks of discolouration were manifested along the right arm and right side of the trunk. A violent paroxysm of vomiting followed the restoration to a state of sensibility; which continued, with occasional interruptions, for ten or twelve hours. As in the preceding case, she complained very much of pain in the region of the stomach and bowels, for at least two weeks after the accident. A troublesome sensation of burning was experienced in the palms of her hands and the soles of her feet; and in the course of two or three weeks a swelling made its appearance under

right foot, which ultimately resulted in the exfoliation of a portion of the thick, indurated epidermis of that part, about one and a half inches in diameter.

"The catamenial discharge, which had, in accordance with the ordinary arrangement of nature, ceased for more than twenty years, was completely and, thus far, permanently re-established! At least, a discharge from the genital organs, having all the obvious and sensible physical characters of the catamenia, and observing, with rigorous exactitude, its peculiar law of periodicity, has been established, and continues to recur, with the utmost regularity, up to the present time (Aug. 1844), after the lapse of more than a year! She has not missed a single menstrual period since she was struck by lightning. To use a liberal paraphrase of her own language, her "Moons return as regularly as when she was a young woman." The flow comes on with the usual premonitory symptoms. Her mamæ have undergone an obvious preternatural enlargement, apparently originating in a sympathetic irritation, emanating from the establishment of the reproductive functions. This woman has had but one child, to which she gave birth soon after reaching womanhood. The catamenial flux is represented to have been regular up to the period of its natural cessation, between forty-five and fifty years of age; subsequent to which epoch she has presented all the appearances ordinarily attending the gradual approach of the state of senility in a vigorous constitution. The electrical shock, likewise, completely relieved her of a troublesome strangury which had harassed her for four or five years. Very recently she has, occasionally, had a very slight recurrence of the same complaint, although under a much milder form. Otherwise, her health continues perfectly good; there being, so far as symptoms show, not the slightest indication of the supervention of organic disease of the uterus."—*New York Journ. of Med.*; and *Amer. Journ. of the Med. Sciences*.

CURIOUS MALFORMATION CONNECTED WITH CONGENITAL IMPERFORATE ANUS.

A FEMALE child, two days old, was brought to the Hôpital Saint-Louis to be operated on by M. Boyer, for an imperforate anus. There was no external sign of an orifice in the region of the anus; the abdomen was tympanitic and painful. M. Boyer made a small incision in front of the coccyx, and examined carefully, with the end of the finger, the bottom of the wound. Finding a fluctuating tumor, he, without hesitation, inserted into it a trocar, when the escape

of stercoraceous matter in a liquid state led to the supposition that the instrument had penetrated into the intestine; the abdomen decreased in size, and for a short time everything progressed favourably. Peritonitis, however, ensued, and the child died.

Necropsy revealed the following condition of things:—The rectum terminated in a pointed *cul-de-sac*, immediately behind the bladder, and it seemed as though it had been tied with a ligature; it contained hardened fecal matter, and its cavity communicated by two very small openings, the one with the bladder, and the other with two distinct sacciform bodies, placed on each side of the bladder. These two sacs were about the size and shape of the thumb of an adult; each one was found, on a close examination, to consist of a uterus and vagina; and these two uteri and vaginae, situated on each side of the bladder, received, as through a conical filter, the liquid portions of the matter contained in the intestine. It was into one of them that the *trois quarts* was found to have penetrated.—*New York Journ. of Med.*

FRIDAY, MARCH 21, 1845.

RECORD OF CASES.

By ALEXANDER URE,

Fellow of the Royal College of Surgeons of England; and Surgeon to the Westminster General Dispensary.

(For the Medical Gazette.)

Tubercular thickening of the Lip, successfully treated by Iodide of Potassium.

Mrs. H., aged 28, admitted the 16th Sept. 1844. The upper lip is greatly enlarged and prominent; its external surface is the seat of superficial ulcers, for the most part covered with crusts. The affection commenced six months previously as a hard round swelling in the right side of the lip, unattended with discoloration. The swelling subsequently extended over the whole lip, and is always most conspicuous in the morning. Several indurated tubercles can be felt imbedded throughout its substance. States that her general health is good. Her tongue is clean, but the pulse is rather frequent, and she complains of thirst.

Ordered a solution of Epsom Salt and Tartar Emetic twice a day; and to pencil over the excoriated surface every morning with a lotion containing ten grains of Nitrate of Silver dissolved in an ounce of pure water.

23d.—Sores are all healed, but the swelling remains as before.

To take five grains of Plummer's Pill, night and morning.

27th.—No change in the condition of the lip.

Ordered five grains of the Iodide of Potassium, dissolved in water, twice daily.

Oct. 4.—The swelling is considerably diminished; the tubercles much lessened in size.

To continue the Iodide of Potassium.

903.—xxxv.

8th.—Tumefaction quite gone; no tubercles to be felt.

The above case exemplifies, in a striking manner, the power of iodide of potassium in promoting the absorption of a variety of tubercular deposition, which seemed to bear some resemblance to elephantiasis in its primal stage.

Periosteal thickening, yielding to the use of Iodide of Potassium.

Mrs. G., aged 28, admitted 11th Sept. 1844. Occupying middle third of left ulna is a prominent swelling, extending over a space of two inches. There is a slight tenderness on pressure. The superimposed skin presents a faint reddish blush. Occasional throbbing pain is experienced in the part affected, shooting down to ring and little finger in the course of the ulnar nerve.

The pain is so bad at night as to prevent sleep. The affection commenced about two months previously, shortly after her last confinement. Her general health is indifferent, and she complains of debility. Has been under the care of a medical practitioner, and applied blisters and plasters, but without deriving any benefit.

Ordered six leeches to the part, to be followed by a lotion containing diacetate of lead.

Sept. 13.—Redness abated, but the pain persists.

To take two grains of iodide of potassium in an ounce of compound infusion of gentian twice daily, and one grain of opium at bed-time; bran poultices to be applied to the arm.

Sept. 27.—Has persevered steadily in the use of the above remedies; the swelling and pain of the arm have altogether subsided. Now suffers only from weakness. Under the employment of infusion of cascarrilla with ammonia she progressively improved, and ere long ceased to attend.

Diffuse cellular inflammation caused by a splinter of an iron hoop.

M. H., aged 49, a drayman, admitted Dec. 9, 1844. Five days prior to the above date, while lifting a cask, a splinter of rusty hoop was forced into left thumb. The thumb is swollen to twice the natural size; the integuments are hot, tense, and of a dusky red hue, as is also the case with the hand and wrist. He complains of constant throbbing pain, referred to the volar surface of the thumb. Has been in the habit of drinking freely of beer and spirits. Was leeches prior to my seeing him. I made a free incision through the soft parts down to the bone; prescribed for him every four hours a dose of the saline antimonial mixture formerly mentioned; and bran poultices to be applied every four hours; low diet.

Dec. 11.—The swelling, tension, and redness of the hand and wrist, rather increased. The opening, from whence some ichorous matter issues, was enlarged in the direction of the apex of the thumb. Several punctures with a lancet were made into the tense skin over the back of the hand and thumb. Tongue much furred.

To continue the poultices, emeto-cathartic mixture, and to take directly five grains of calomel.

Dec. 13.—Tension and redness much lessened: a piece of iron hoop came away yesterday. There is now some boggy swelling of the hand, extending beyond the wrist a little way up the forearm. The wound in the thumb discharges freely. Expresses himself as feeling much more comfortable, though the fingers are hotter than usual.

The same treatment to be continued.

Dec. 16.—Swelling much abated; the hand begins to assume its natural aspect.

Dec. 18.—Progressive improvement in all respects. Wound in thumb is granulating, discharge less.

Dec. 23.—Granulations now on a level with the surface; still some doughy swelling at wrist, and dusky redness; is acquiring some command of the fingers, heretofore stiff and motionless. The thumb was dressed with strips of adhesive plaster, a roller applied over the hand and forearm, and kept moist with an evaporating lotion. As his bowels were rather confined, he was ordered—

To take five grains of blue pill, with as much compound extract of colocynth, every other night.

This patient went on favourably up to the 11th of Jan. 1845, when there was a fresh accession of tense swelling at the upper and fore part of the thumb, into which I made a free incision with a bistoury. This bled copiously, and gave immediate relief.

Jan. 13.—Two splinters of rusty iron came out of the wound this morning. After this occurrence it slowly healed, and recovered its natural appearance by the 7th of February. A fortnight afterwards he resumed his work.

The above case illustrates the fact that habitual excess in the use of fermented liquors renders persons liable to inflammatory attacks of a severe kind and of a specific character from apparently trifling causes. Here the subject was a brewer's servant, in whom the accidental introduction of a scale of iron rust induced a diffuse and extensive cellular inflammation. The splinter, which entered by an opening in the lower part of the thumb, must have been subsequently broken by the muscular movement, for it came away piecemeal. It is curious that two of the fragments should have quietly worked their way to near the apex, and been eventually evacuated through an artificial aperture in that situation. Had an incision been made from one end of the thumb to the other, in the first instance, it is possible the whole extraneous substance might have been more readily removed; but the account given by the man touching the probable size of the splinter did not seem to warrant such practice.

Erectile tumor of the eyelid, treated by inoculation with croton oil.

Mary D., aged 3½ months, admitted Dec. 30, 1844. At the inner angle of right upper eyelid is an erectile tumor nearly as big as a currant. It appeared like a scratch at the period of birth, and has progressively reached its present size. It has, however, been growing more rapidly during the by-gone month. There is a reddened villous condition of the palpebral conjunctiva subjacent to the tumor. The child is in other respects very healthy. I first of all tried the plan of subcutaneous puncture, employing for this purpose a common iris knife. A repetition of the procedure after the lapse of weeks appeared to have no effect in reducing its volume. Towards the middle of February I had recourse to inoculation with croton oil. I accordingly made several minute punctures with a cataract needle, besmeared with the oil over the surface of the nævus. This gave rise to redness and swelling, which lasted a few hours, and subsequently to small points of suppuration. This tiny operation was repeated at an interval of a week. The result has proved a rapid diminution, with withering, of the tumor; and now scarcely a vestige remains, with the exception of a slightly puckered speck at the corner of the eyelid.

In a case like the above the employment of the knife would have been inadmissible, not only on account of serious hæmorrhage, but because the cicatrization of the wound

might lead to eversion, or shortening of the lid. The use of the seton, escharotics, or vaccination, would have been equally contraindicated, owing to the risk of violent irritation, or of sloughing. The sole object was to create inflammation enough in the parenchyma of the nœvus, and which might be perfectly under control. For the plan of treatment by inoculation with croton oil, the profession is indebted to M. Lafargue, a French surgeon. Not more than five or six punctures ought to be made at one time. A common lancet may be used for the purpose, just as in vaccinating.

Ulcerated pile, treated with chromic acid.

J. L., aged 31, tailor, admitted April 27, 1844. At verge of anus is a dark hemorrhoidal tumor, the bigness of half a walnut, of which the surface is ulcerated and extremely painful. The tumor had been extruded several days, and various attempts at reduction proved of no avail. The patient seemed in a most deplorable state, haggard, and worn out by suffering, from which he could only obtain a brief respite by observing a half-bent posture. He had been subject to piles for some years. The bowels were open. I applied the chromic acid freely over the whole of the diseased surface.

April 29th.—Says that he felt considerable uneasiness in the part during the whole afternoon following the application. He is now quite comfortable in all respects. A considerable slough has been detached, and the excrescence is withered and shrunk to the bulk of a raisin. Bowels confined.

Half an ounce of castor oil.

May 1.—Complains of a feeling of aching referred to the sacral region; bowels torpid; inappetence for food; sense of languor and listlessness.

To take an ounce of compound infusion of gentian, with a drachm of Epsom salt, every morning.

May 13.—Perfectly cured. The trifling remains of the pile are wholly insensible, and create no inconvenience whatever; his bowels act naturally.

Chromic acid is, as every chemist knows, a most powerful oxidizing agent, yielding half its oxygen readily to organic substances, and being reduced to sesquioxide. On this principle, I was led to employ it as an escharotic. It is exceedingly convenient for application, inasmuch as it consists of a thick crystalline pap, which, when rightly managed, does not spread beyond the prescribed limits; and so soon as its erosive operation is finished, passes into the state of inert pulverulent sesquioxide, above mentioned.

My colleague Dr. Child, of Mortimer Street, requested me on the 30th of May,

1844, to see Mrs. W., aged 30. For a month previously she had been suffering much from two hemorrhoids situate upon the right side of the verge of the anus, each about the size of a kidney bean, and was anxious to obtain alleviation. Various external and internal means had been already employed, but in vain. She had been troubled with piles at different times during the preceding eight years. Her general health is tolerably good, and the bowels usually regular. Since her last confinement, ten weeks ago, she has complained of shooting darting pain referred to the anus. It was determined to apply chromic acid, which was accordingly done. It was found necessary to repeat the application on the 1st of June. This caused acute burning pain both times, destruction to a considerable amount of the diseased texture, consolidation of the remainder, and permanent relief from the distressing ailment.

Gout treated by belladonna and naphtha.

J. P., a German courier, aged 45, admitted Nov. 13, 1844. Of spare habit and sallow complexion; his habits of living are moderate and regular; of late rather sedentary. Complains of racking pain in ball of great toe of left foot, which is red and swollen. The pain is worst about four o'clock in the afternoon, and abates towards bed-time. It came on suddenly, as if from a wrench, on the morning of the 10th curr. Pulse 96, weak; occasional chills; tongue a little coated at the base; urine natural; sleeps ill. He had a precisely similar attack three years ago, which lasted a fortnight.

To apply, with gentle friction over affected surface, an ointment composed of one part of extract of belladonna, and eight of cerate, and to take five grains of blue pill, with five of extract of colocyath, at bed-time.

Nov. 15.—The pain is dulled, but the toe is still swollen, and dusky red; bowels are open.

To use mineral naphtha as an embrocation.

22d.—Derived direct benefit from pencilling over the part with naphtha; the pain, redness, and swelling, are now wholly removed. Feels quite recovered.

This case is adduced in order to show the topical efficacy of rectified coal naphtha in the subacute form of gouty inflammation, as pointed out in a paper I published in the *MEDICAL GAZETTE* for last year. The patient was a German courier, who had been more or less accustomed to fare well, both as regards eating and drinking. His recent sedentary manner of living would certainly tend to rouse into activity any gouty disposition lurking in the system. The pain was assuaged in the first instance

by the belladonna salve, but no decided melioration ensued until recourse was had to the naphtha.

Circumscribed tumor of the breast.

M. W., aged 27, cook, unmarried, admitted under me Oct. 10, 1844. In April last, she perceived for the first time a circumscribed swelling, the bigness of a hazelnut, at the lower inner portion of the right mamma. It has gradually been shifting its position upwards, and is now imbedded in the upper and sternal part of the breast. It is of the size above mentioned, not having increased sensibly since first noticed. It is hard, irregular, freely moveable, quite unconnected to all appearance with the mammary gland. There is no drawing in of the nipple.

The tumor is unattended with pain. She ascribes its origin to pressure of the stay-bone. Her general health is good, and catamenia regular. Has three brothers living who enjoy good health, her father died of consumption.

To guard against local pressure.

Dec. 29th.—Has experienced neither pain nor inconvenience since last report. Health continues good. The tumor remains unchanged.

This seems to be one of the lobular tumors of the breast, described by Sir Benjamin Brodie, and which are not of a malignant nature. Cases have come within my cognizance in which they have persisted during thirty years, without any material alteration. It is curious, that pressure, which has from time to time been recommended as a means of cure for various morbid growths, even including cancer, should have been here the "*fons et origo mali*." Pressure, indeed, may occasionally promote the absorption of oedematous fluid and adipous texture, which surround a scirrhous mass, but cannot disperse truly carcinomatous structure itself.

Incontinence of urine caused by the use of bicarbonate of soda.

Mr. H., aged 68, came from Buckinghamshire to consult me on account of the following symptoms.

May 25th, 1844.—For the last six months has laboured under incapacity of retaining his urine, which comes away at frequent intervals and in very small quantity. Each emission is accompanied with pain along the course of the urethra, but nowhere else. The bowels are apt to be moved simultaneously with the flow of urine. His general health is good, as also his appetite. The bowels act without the aid of physic. Would sleep well were it not for the frequent calls to micturition. The prostate gland is

of the natural size, and there is no trace of calculus within the bladder.

The urine affords an alkaline reaction with red litmus paper immediately when voided, and evolves at the same time a faint ammoniacal odour. Its specific gravity is 1.010. It is deficient in uric acid and in phosphate of lime; deposits, after being allowed to stand a few hours, ropy mucus and crystals of ammoniaco-magnesian phosphate. A few pus corpuscles are visible on microscopic examination. The urine becomes turbid upon exposure to heat.

He ascribes his infirmity to the use of bicarbonate of soda, of which he formerly swallowed half an ounce every week to relieve indigestion. Has latterly derived much benefit from a mixture of liquor potassæ and spirit of nitric ether, but has not taken any during the last eight days.

I prescribed 4 grains of benzoic acid, made into a pill, with balsam of tolu, to be taken thrice, and a couple of capivi capsules twice a day.

This gentleman visited me again upon the 22d of June, improved materially in all respects. He is able to hold his water a couple of hours; it does not dribble away as formerly while at stool, nor is he obliged to get up oftener than twice in the night. He no longer experiences the pain in the urethra.

The urine is now limpid, acid, remaining so after standing forty hours. Its specific gravity is 1.016. It is scarcely affected by heat.

At his own request the same remedies were continued, and with sustained benefit.

Nothing could be more satisfactory than the effect of the benzoic acid and capivi in correcting the above unhealthy state of urine. The uneasiness formerly experienced during its discharge was unquestionably due to its alkaline quality; for in this condition it always irritates the mucous membrane of the urinary passages with which it comes in contact.

The preceding case is brought forward chiefly with the view of putting dyspeptics on their guard touching the injurious consequences which may arise from the indiscriminate and prolonged use of bicarbonate of soda. A nearly parallel instance is recorded in a paper of mine relating to calculous concretions, published in Vol. I. of the Pharmaceutical Journal and Transactions. An intelligent chemist, in the vicinity of London, after using the aforesaid preparation for eighteen months to relieve acidity of stomach and heartburn, was seized with inability to retain his urine, accompanied with the discharge of white concrete matter from the bladder, which troublesome symptoms rapidly subsided on discontinuing the medicine.

OBSERVATIONS

ON THE

NATURE AND TREATMENT OF THE
MORE IMPORTANT DISEASES
OF THE NERVOUS SYSTEM:*With Illustrative Cases.*

By EDWARD BLACKMORE, M.D. Edinb.

Member Extraordinary of the Royal Medical
Society of Edinburgh, and Physician to
the Bath Penitentiary.

[Continued from page 766.]

SECT. III. CHOREA.

CASE X.—A girl, aged 11, was seen October 10th, 1829, affected with severe pain in the forehead, and sleeplessness; fits of loss of sense, attended with a heaving at the præcordia, and a noise in the throat as if strangling; then with twitches in the arms, and a falling down, as if from sudden loss of power in the legs; the pupils dilated.

Leeches, purgatives, alteratives; and blisters to the neck and sacrum.

The 26th, she was much better.

A third of a grain of nitrate of silver thrice a day.

29th, the head worse.

Mercurial purgatives.

Nov. 21, a gait in walking as if more more complete chorea forming; belly tumid, lax; tongue red.

Antacids and henbane.

The diarrhœa quickly ceased, and as she exhibited a cold nervous aspect, the nitrate of silver was resumed. After this more headache, and a return of the spasms, for which mercurial purgatives were given with relief; then a cough, which was relieved by squills and ipecacuanha. After this, pain in the head and feverishness required leeches and purgatives; but about the 23d the symptoms became severe, in evening paroxysms, with loss of sense, and spasms of the eyeballs.

Head to be shaven, an issue, and purgatives.

By the 8th of December the improvement was marked; carbonate of iron was then ordered, and in a fortnight more she was cured.

CASE XI.—A boy, aged 10, after a severe chill on December 29th, 1829, was affected with pain at the forehead, costiveness, and severe chorea.

January 6th, the countenance fatuous; little fever.

Leeches, mercurial purgatives, antimony, and rest in bed.

The 8th, the head relieved; spasms the same; costiveness remaining.

Purgatives.

In the next four days there was little amendment, and he was bled to six ounces; the coagulum was loose and florid; and on the 13th, the pulse being soft, nitrate of silver was given, and clysters repeated.

On the 14th, severe spasms of all the muscles, particularly of the jaws, on attempting to drink; saliva spat involuntarily from the mouth; the bowels purged of a vast quantity of stool.

On the 17th, four half grain doses of the nitrate were alone given; and in the evening three large feculent stools were passed.

18th, headache and spasms severe; pupils large and sluggish; tongue dry, and its papillæ swollen; the pulse weak.

The nitrate of silver stopped, twelve grains having been taken in the whole; the scalp blistered; leeches and mercurial ointment on the head; calomel, scammony, and tartarized antimony, with salines.

The 20th, purged of more natural stools, and the look of oppression relieved; he has slept well, and speaks intelligibly for the first time.

The 25th, exhaustion; pulse 80, weak; tongue aphthous; no salivation; free purging; the respiration a succession of deep sighs at long intervals; severe spasms of the limbs; much emaciation; inability to speak; sleep much disturbed; eyes vascular and turgid, but the pupils more natural, and the countenance clear and intelligent. He has used a drachm of calomel in three weeks, and half an ounce of stronger mercurial ointment.

Salines repeated.

27th, less exhaustion; bowels natural; and he speaks a little.

28th, better.

Sulphate of quinine, and meat broth.

February 4th, chorea nearly gone.

Oxide of zinc, with rhubarb.

In ten days more he was quite well. This boy, in the spring of 1831, got a similar but less severe attack, and

was cured by similar remedies; and in the spring of 1832, he had chorea of the right limbs alone, without the fatuous expression of the countenance; the pulse strong in the left arm. He was cured by purgatives of calomel, jalap, and gamboge; a blister and rubefacients on the spine; and then carbonate of iron with valerian.

CASE XII.—A girl, 14 years of age, was affected, March 12th, 1831, with severe chorea. On the 18th the spasms were incessant; the tongue and jaws much affected; the bowels costive; the pulse low.

Cupping-glasses on the spine, and mercurial ointment; clyster and purgatives; salines and colchicum.

The 23d, the spasms excessively strong.

Remedies continued.

26th, a little better; no pain; tongue clean; pulse soft.

Clyster repeated.

28th, spasms better, but sleeplessness distressing.

Mercurial ointment continued.

31st, the mouth sore from mercury; convulsions of the face and limbs continue, but are less severe; more natural appetite, and natural stools.

Clyster and ointment as before.

April 16th, chorea less violent.

By the 29th she was nearly well, after having been electrified seven times.

CASE XIII.—A robust boy, 3 years of age, was observed, in the winter of 1824, to be affected with sudden but momentary failure of voluntary power in the right side, so as to make him fall down sideways; there was also, at intervals, a convulsive movement of the limbs, and an occasional squint. The stools were without bile.

Leeches to the neck; the tepid bath; purgatives and calomel.

After this he voided worms, and, on taking an emetic, he brought up one from the stomach. In a few days the bowels were natural, but the failure of voluntary power continued. Small doses of sulphate of zinc, with opium, were then given, and the symptoms ceased.

The case resembled that named by Sauvages *Scelotrybe instabilis*, a variety of chorea. The affection returned,

after an intermission of five months, at the end of spring; when small doses of oil of turpentine were given, after which more ascarides were voided. He was then vomited and purged by a large dose of the turpentine, followed by calomel and scammony; and by a blister to the neck, and rest in bed, and continued purgatives. He soon got quite well.

CASE XIV.—A female, aged 20, who had suffered in the latter months of 1842 with severe headache, and various nervous symptoms, referred to a spinal disease, came under my care in January 1843, in a debilitated state, and with the headache unrelieved; no disease of the vertebræ could be detected. On cutting off the hair, sponging the head, using citrate of iron, with a mild tonic diet, and taking her out of the bed-room, she soon became convalescent, and remained in good health to September of the present year, when, after spraining her foot, an occasional twitching of the mouth, eyes, and arms, was observed. About the middle of October she was recommended to pour cold water on her foot for the sprain, and shortly afterwards was attacked with a severe sore throat, which yielded to the ordinary remedies, but was followed in a week by hemiplegia of the right side, with hysteria, and severe chorea of the face and left extremities. I saw her in consultation with her very intelligent surgeon, on November 12th, when the right arm was insensible and powerless, the leg also palsied in a slighter degree; the face affected with spasms; the eyes very protuberant, and the pupils dilated. She complained of pain at the occipital region and right temple; and the cervical vertebræ, and the lumbar and abdominal muscles were very tender; her sleep heavy, and manner fatuous; the tongue clean; the pulse rather low; the skin cold; the appetite voracious; the bowels had been torpid until regulated by medicine; the menstrua were regular.

The hair to be cut off, and the head sponged with an evaporating lotion; dry cupping-glasses on the neck; aloes with blue pill daily, and sulphate of potass in a bitter infusion, to purge actively.

In a week the pain at the hind-head was relieved, but the palsy remained; the chorea was stronger and more general; fatuousness increased, with fits

of severe mental irritation, and violent hysterical symptoms; her speech much impeded; the pulse not disturbed; the extreme circulation low; the eyeballs more prominent; the pupils sluggish, but not fixed; the stools unhealthy, containing a quantity of black bile. On one day, when the aperient was omitted, the spasms were much worse.

The head to be shaven, the occipital region blistered; cupping to six ounces on the neck; the limbs to be swathed in flannel; iodide of potassium in infusion of rhubarb, and compound scammony powder, to purge daily.

In a few days the fatuousness and the palsy were lessened, but she now complained of acute pain at the right temple, and at nights had strong fits of hysterical and maniacal excitement. The medicines afterwards acted well on the bowels, and she ceased to complain of the head; but it was hot, and the pulse had risen to 90. This exacerbation seemed to be owing to an error in diet, as eggs, coffee, cocoa, and sal volatile, had been given. A stream of cold water was then ordered for the head, the room to be darkened, the weather being sunny, and fresh air admitted; and on the 25th the paroxysms were milder, the mental powers at times natural, the palsied limbs improved, but the spasms of the eyelids and jaws, the projection of the eyes, and severe pain at the right temple, continued. On knocking this part gently, the pain was increased, and a spasm and swooning induced.

An incision, three inches long, was then made along the edge of the right temporal muscle, down to the skull; and the scalp being very vascular, was allowed to bleed to six or eight ounces. She then became faintish, a warm perspiration broke out, and the pulse fell from 92 to 66. She afterwards slept calmly, and the next day exhibited the most decided improvement, expressing delight at the relief of the pain. The wound was then dressed to keep up suppuration; and croton oil with colocynth, and small doses of the bichloride of mercury with hydrocyanic acid, were given for ten days, during which her amendment was uninterrupted. About December 8th, however, the issue had nearly healed, the liver had become disordered, the stools scybalous and clay-coloured; the palsy and the spasms of the face had returned, with

fits of hysterical excitement, fatuousness, and disturbed sleep. After some blue pill, with aloes and saline purges, the stools were improved, and the nervous excitement lessened; but on the 14th the eyeballs were again prominent and squinting, the pupils dilated, the arm powerless, the head severely pained, and percussion of it gave evident distress; the pulse was quick, and the tongue clean.

The head to be again shaven; antimonial-mercurial ointment on the scalp; the neck blistered, and alterative aperients continued, with a vegetable diet.

On the 16th, the symptoms not being better, eight leeches were applied, and six more on the following day, with little effect.

On the 19th there was more of a comatose tendency, with severe pain in the occipital, frontal, and left temporal regions; and slight percussion of the hind-head again induced spasms of the left arm and leg, and hysterical sobbing; the left eye particularly prominent and vascular,—its pupil dilated; the face flushed; the pulse quick and full, particularly in the left wrist; the speech indistinct, and the tongue put out with difficulty; the left arm was now the palsied limb, the left leg also weak. The bowels had been freely purged with aloes and calomel, and the scalp extensively pustulated with the ointment. Tickling the soles of the feet had no effect on the functions of the spinal chord.

It was evident that while the right portions of the encephalon were relieved, the left had become affected with severe congestion. The next day she had passed a better night, after taking antimony with nitre, and a black draught; but the pulse was 120, and the other symptoms persisted. A deep incision, five inches long, was now made along the left side of the head, and allowed to bleed to ten ounces; after which she spoke distinctly and sensibly.

Nitre, with tartarized antimony, ordered twice a day; an aperient every morning; mercurial ointment on the thighs, to salivate.

21st, no complaint of the head; no spasms. The head poulticed.

23d, the eyeballs still projecting; the left arm still powerless, and at times tossed with spasms; the right able to

grasp firmly. No hysterical symptoms since the incision.

It was manifest to her medical attendants that considerable serous effusion had taken place in the left ventricle; but a confident hope of recovery was entertained. The same treatment continued.

27th, a delightful improvement; yet still slight palsy and spasms of the left arm; the issue discharging freely.

January 2d, amendment more complete; no spasms; no palsy; the eyeballs natural; issue in a good state; the mouth soreish from the inunction, but no salivation; she is able to walk from the bed to her chair without giddiness. Convalescence fairly begun; but the remedies to be continued for a short time, as a precaution against a relapse.

The 13th, progress to recovery satisfactory.

SECT. IV. HYSTERIA.

CASE XV.—A female, aged 22, on June 9th, 1828, after costiveness for several days, got severe pain in the head and stomach, followed by sudden and dreadful hysteria; the spasms of the limbs, eyes, and respiratory muscles, extremely severe; the face black from the interrupted respiration; the pulse extremely low. She was bled to twelve ounces in the fit; the blood was very florid, and the clot soft. Purgatives and clysters procured several stools; but in a few hours the spasms returned severely, when ammonia and a foetid clyster were given. In the course of the night the convulsions were so severe as to threaten suffocation; she had also acute pain at the hind-head, and in the chest, with a spasmodic cough, cold perspiration, and a very depressed pulse. On the spasms remitting, the pulse became natural. The hair was then cut off, ether and laudanum given in a clyster, and rubbed on the spine. In a few hours the spasms returned, with acute pain in the head, and throbbing; the pulse full. Senna and salines were given.

The 11th (third day), the spasms subsided, headache continued, with a furred dry tongue and a full pulse; two large stools passed.

Leeches, salines, and purgatives.

The 12th, copious purging of faeculent mucous stools, with relief of headache; then a return of convulsions,

and relief after a natural stool from senna.

The 13th, severe headache and tenderness at the epigastrium, with intense thirst; pulse natural.

Salines, laxatives; and a blister on the spine.

The next day much relief after natural stools.

15th, a return of spasms. Senna ordered.

The 17th, a nervous hysterical state; a cough, inducing spasms and hiccup.

Ammonia, valerian, camphor, and henbane; wine.

After this the hysteria ceased, but was succeeded by acute pain in the side, impeding respiration, which was relieved by leeches and purgatives; and in a few days convalescence was advanced. On the 26th, however, a severe convulsive cough, with convulsive breathing, and a little spitting of blood, were induced by mental agitation; which were relieved by henbane and assafœtida; and in July her usual health was restored by quinine and country air.

CASE XVI.—*Palsy of the hand connected with suppressed menstruation, cured by galvanism; succeeded by inflammation in the brachial and intercostal nerves? Morbid effects of loss of blood while menstruating; spasms of the heart, gullet, and respiratory muscles; tetanus and syncope. Singular morbid effects of galvanism.*

A female was affected on November 16th, 1819, with a sense of numbness, followed by a loss of muscular power and impaired sensibility of the left hand, without emaciation of it; and with occasional pain in the head, and costiveness; the menstrea had been suppressed for a long time.

Aloes, gamboge, and colocynth; ammoniacal liniment on the hand.

24th, more headache, with costiveness.

Twelve leeches to the temples.

25th, electricity to the hand daily.

Dec. 1st, headache and vertigo.

Leeches.

3d, pulse 100, strong.

Bleeding to sixteen ounces; other remedies continued.

4th, head symptoms relieved; palsy as before.

A blister on the fore-arm.

9th, hot brine, and afterwards dry hot salt, to the arm.

18th, galvanism to the hand,—now in sixth week of palsy, with little change.

24th, galvanism applied three times in the day, as strong as could be borne; a sensation of warmth from it; no increase of motive power.

Remedies continued.

26th, a power of moving the thumb and fingers; the sensibility of the hand so much increased, that during the application of the galvanism warm water to it is intolerable, as well as the brine and hot salt.

28th, galvanism for two hours and a half a day, at three times; palsy much improved; now able to lift a heavy weight. The galvanism was continued for some days, and then omitted, because of the pain it induced.

January 4th, motive power again impaired; severe pain felt shooting up the wrist, on immersing the hand in hot brine.

10th, galvanism repeated. In a few hours she complained of severe pain in the left side, increased on a full inspiration, with a cough, while menstruating.

On the 13th she was bled to twelve ounces.

The 14th, pain at side and cough continuing, and the pulse 95, full, and hard, she was again bled to twenty-four ounces, in the morning, with immediate relief of the symptoms, and the bowels were purged by medicine. At noon day pain was still felt on inspiring, and the pulse 96 and full; a blister was then applied on the side. In the evening, the pulse being 80, and full, with much headache and pain in the side, bleeding was repeated to twenty-six ounces, without any relief of the pain; and instantly afterwards she became deadly faint. On the head being placed low, and the jugular veins compressed, sense was restored; and as she recovered she was seized with dyspnœa, which increased in severity until half a drachm of laudanum and sulphuric ether was given. During the night the sleep was broken with two slight attacks of a similar nature, and the next morning the side pain was no better, and still increased by a full inspiration; there was also headache, pain at the epigastrium, thirst, the

tongue natural, the bowels purging freely, the pulse 98, strong.

Twelve leeches on the epigastrium; inhalation of steam.

Soon after the leeching syncope returned, and was followed again by severe dyspnœa. She then complained of a great weight pressing on the sternum, taking her breath away, and again became insensible. The inspirations, at first 40 in a minute, then more and more convulsive, and never under 80. The pulse, at first 100, and full, then rose to 150, and could scarcely be felt; the eyes became fixed; the countenance expressive of agony; some convulsive startings, similar to those she had been affected with during the use of electricity, were observed on the arms and chest during this paroxysm. On becoming more sensible, she felt the greatest difficulty in swallowing; the attempt seemed to excite convulsions in the gullet, and complete opisthotonos for two minutes; the very idea of swallowing seemed also to excite spasms. During this paroxysm, which lasted an hour and a half, she took 80 drops of laudanum with sulphuric ether; but as the ether seemed to excite spasm, it was exchanged for spirit of nitrous ether. A hot foot-bath then seemed to rouse the circulation; and on recovering she complained of pains in the side, palpitation, and a tendency to fainting, with anxiety at the præcordia, and headache. At 6 P.M. twenty leeches were applied to the epigastrium, with relief of pain, but with increase of the dyspnœa; and in an hour and a half a similar paroxysm to the former, but more severe, and lasting for five hours,—fits of syncope alternating with convulsions of three minutes' duration, and generally mitigated by ammonia to the nostrils, and finally relieved by repeated doses of laudanum and spirit of nitrous ether. In 48 hours twelve drachms of the former, with two ounces of the latter, were taken.

The 16th, a sleepless night; palpitation and a tendency to syncope in the erect position; headache; thirst; pulse 88, full; side-pain diminished; bowels regular.

A hot bath, and ammonia, with laudanum, and tincture of castor, in small doses; a blister on the præcordia and an emollient clyster.

The 18th, better.

20th, five drops of tincture of foxglove given every three hours, which excited vomiting; clysters of laudanum and assafoetida relieved her.

24th, still better as to the hysteria, but nausea and vertigo distressing; the motive power of the hand weak.

Fætid clysters given, and galvanism resumed.

Feb. 1st, pain in the palm of the hand by slight pressure, or an attempt to extend it; general nervousness, and debility, and costiveness.

Galvanism and purgatives.

In the evening pain at the side, and a paroxysm of quick convulsive breathing, with loud moaning. The palsied hand kept on the precordia; the other, and the general body, in convulsive movements; the pulse very quick, and at times imperceptible. Two drachms of laudanum were given in two doses, at an interval of half an hour, without effect. At 10 P.M. the body and shoulders were drawn forward by tonic spasm; the respirations beyond 100 in a minute; three drachms of laudanum then given, in three doses, at short intervals. At midnight little improvement; two similar doses of laudanum, (making seven drachms in the course of the evening) with nitrous ether, were then given, and the paroxysm declined. The sleep was disturbed by dreams, and a narcotic influence remained for several hours. The next day, at noon, the affection of the chest had subsided; the pulse 88, respiration calm, thirst intense, and some headache.

Nitrous ether continued.

In the evening a similar but milder paroxysm; relieved by three drachm doses of laudanum, and a turpentine clyster; after which she slept well.

On the 3d, the symptoms were improved, except thirst, with a white dry tongue, and costiveness.

Extract of colocynth.

4th, two easy stools; abdomen still tumid.

Infusion of roses with salts.

5th, a sense of tightness at the chest; inability to inspire deeply.

6th, a slight paroxysm, for which a drachm of laudanum taken. Afterwards purgatives were continued, and she ceased to be under medical care; but the weakness of the hand remained.

This extraordinary case I saw in the practice of a physician now deceased.

[To be continued.]

MEDICINE STAMPS AND QUACKERY.

To the Editor of the Medical Gazette.

SIR,

ALLOW me, at the present crisis, to call attention through your columns to a few points connected with the above. First—as to medicine-stamps. You lately remarked, and truly, that here we have “an object of state finance.” Your data gives an average of about £32,595 annually, for the last thirteen years; and mark a gradual decline, during that period, from about £45,000, to something less than £29,000. Can we not, then, afford to forego so small an item of state finance? especially when we remember the very questionable propriety of its source, and the readiness with which such a sum might be otherwise raised. You suggest that we may be asked, “would you prevent a man profiting by a useful discovery in medicine, when, in other departments of science and art, the State allows individuals to protect themselves by concealment (?), or affords them the exclusive use of their invention for a certain time, if they choose to make it public?” You meet such apparently reasonable interrogatory, most justly, with the answer, that nearly all medicine patents “have been mere impositions.” We may explain ourselves more fully to the non-medical community, who, after all, must have the final adjustment of the question. We may inform them that very many quack-nostrums are downright deceptions; and that such others as are serviceable, are, in almost every case, well-known common remedies in the profession; the oils, the salves, the pills, and what not, which the quack puffs in the columns of our newspapers, being, almost without exception, where they do possess any ascertained virtues, pirated either from our own extemporaneous prescriptions, or our pharmacopœia. Nor is this all with respect to these so-called “discoveries in medicine;” let us ask our non-medical friends—whom we may reasonably forgive, especially at this juncture, for evincing jealousy

of our motives, and scepticism as to the validity of our statement—if, on the one hand, they ever heard of a discovery or improvement, in other branches of science and art, that was patented and handed down, from age to age, without the public ultimately reaping the benefit of it, without let or hindrance? or, on the other hand, if they ever heard of a quack nostrum that was first minutely described and explained at head quarters, and, in the course of time, divulged for the unrestricted benefit of the public, after that the “patentee” had made his own out of it? We may confidently answer, never. If, then, it still be desired to retain so paltry a sum, drawn from so disreputable a source, why not place the quack at least on a level with other “discoverers and improvers?” Why not require an explicit statement of the nature, composition, and presumed or ascertained effects of every nostrum, as in the case of patents, and, in this as in other cases, let the public, in due time, have the full and free benefit of such “discoveries?” and why not prohibit the sale of every unknown drug that is not thus patented, unless specially prescribed for a particular case? And this brings us, in the second place, to the question between registered practitioners and quacks. Sir James Graham, very laudably, proposes to draw public distinctions between these two classes of professors of the healing art—between the men who have spared no trouble, time, or expense, in the acquisition of knowledge in the dissecting-room, the laboratory, the fields, and the hospital, and the men who, with little or no such expenditure of their energies, fraudulently assume the titles so hardly earned by others, or undertake the sacred and responsible duties of physical guardians, even without such cloak. Such distinction as that expected from registration is highly to be prized; in the opinion of many respected members (if not all such) in our profession, the registration plan is about all that can be done, under a free constitution, towards mitigating the evil of quackery—its suppression being by them deemed impossible. Much of the efficacy of the scheme will undoubtedly depend on its being universally acted on by the profession.

Inducements are, perhaps, all that

can be suggested; and if no unregistered practitioner can hold office, or recover fees, by law, probably nothing further is required to cause every one of us to enrol himself. The efficacy of registration, again, only tends to the exclusion of such quacks as assume the titles of the profession; and although certainly, as my friend Mr. Carter rightly observes, these are decidedly the most dangerous of the murderous crew, yet they are but a section at present, and, hereafter, would still exist as avowed and lawless practitioners. Sir James, then, recognises and defeats the fraud, at present practised by many quacks upon their dupes, of assuming University and College titles, while such creatures are—it may be unavoidably—left at liberty to assume the character and office of members of the healing art. Medical men are severely punishable for palpable ignorance of the principles, or carelessness in the practice of their profession; such an arrangement seems well calculated to ensure a full exercise of their talents from the commencement to the end of their career; and no less calculated to beget and maintain for them the confidence of the public. It is proposed by the Home Secretary, and Mr. Carter seems to hold, also, the opinion, that quacks should be similarly amenable to the law; but if the view just taken of the effect or tendency of such “check” be correct, would quackery not rather be cherished by it, through the knowledge, on the part of the public, that the vile pretenders to the medical character were practising in honest and well-grounded confidence, inasmuch as they were doing so under an imminent peril? Although apparently a strange proposition, may it not in reality be worth while to weigh well the policy and propriety of subjecting the quack to any such restriction? Or if Sir James, in his well-meant endeavour to protect the public as far as possible against the most heartless and ruthless of swindlers, be averse from releasing (and thus apparently patronising) them, if still he should incline to the laying on of additional embargoes, might he not, further than by his present plan, attain his end by enabling the dupes of quacks to compel them to disgorge in cases of unsuccessful treatment? Unregistered men are not to recover fees by law;

this, like ineligibility to public offices, is, as you properly pointed out, a mere dead letter, quacks having no book-debts, unless attested bonds can be so considered. Might all such bonds not be rendered null and void? Might not quacks—as assuming the power to cure diseases with the seat and nature of which they are absolutely unacquainted—and as unregistered persons, in case of their unqualified promises, be made liable to prosecution for obtaining money under false pretences? Some such plan is required; for, in truth, we cannot say that, although practising as avowed quacks, their dupes applied to them wilfully and with their eyes open; the public know not the quack otherwise than as a self-taught genius, or fortunate discoverer in the healing art, and as a man justly, and (as they think) for very obvious reasons, dreaded and persecuted by a humdrum body of disciplinarians, who are but too fortunate in having the law at their backs, but for which they would soon be sent to the wall by their naturally more gifted rivals,—a conspicuous, but far from unique example of that tendency, inherent, and so strong, in all of us, to admire and encourage, and expect wonders from, a man, in proportion as his opportunities for acquiring a knowledge of his art in the ordinary way have been restricted. The difference, however, lies here; in statuary, in painting, or in the acquisition of languages, a man's actual proficiency is carefully tested, and justly estimated. With the quack it is precisely the reverse: his capabilities never have been, and as careful is he that they never shall be, tested. The only guarantee that the public can have of medical competency is through the accredited boards of examination, and through the duly authenticated publication of hospital and dispensary practice. From all competent inquirers the quack shrinks; no law is requisite to prevent either his appointment to public offices, or his appearance in open court to extort payment from his miserable dupes: the former he instinctively avoids, the latter he takes good care never to require. To open the eyes of the public, it is not merely necessary to apprise them that the quack is neither physician nor surgeon; they must be taught, if possible, that he is an empty and unscrupulous pre-

tender to knowledge and power that can only be acquired where he has never been.—Believe me, sir,

Yours very respectfully,

R. ELLIOT, M.D.

Member of the Council of the North of England Medical Association.

March 5, 1845.

[A correspondent suggests that it would be a good plan for quack advertisements to pay ten times as much as they do now, particularly as the duty is materially lessened upon all drugs, whereby the impostors may be more than ever offensive; or that the stamps on boxes, bottles, &c. ought, at all events, to be much increased, as the only means of keeping quack puffs out of the public papers.—*Ed. Gaz.*]

ON HEPATALGIA.

By R. H. ALLNATT, M.D., A.M., F.S.A.

To the Editor of the Medical Gazette.

SIR,

RECENT researches into the pathology of the intestinal mucous membrane have especially directed the attention of modern practitioners to this hitherto comparatively unexplored field; and inflammation of the liver, and the subsidiary diseases to which they owe their origin, have received of late years peculiar elucidation from authors. The subject, however, of my present paper has been by almost every systematic writer entirely overlooked, or touched upon in the most cursory manner possible. This is the more extraordinary, as it is a disorder of very common occurrence; but perhaps our surprise should cease when we consider how generally hepatalgia has been confounded with active, or sub-acute inflammation. I purpose, therefore, giving a few brief details of its leading features.

Andral has introduced the following observations in his "*Clinique Médicale*." "We sometimes," he says, "observe in the region of the liver severe pain, which cannot be accounted for, after death, by any lesion of the viscus or its excretory ducts. These are cases of hepatalgia, or hepatic colic. The circumstance just mentioned, and, moreover, the nature of the pains, their intermission, and the state of good

health which often exists in the intervals, all lead us to believe that the pains have their site in the numerous nervous filaments which are distributed to the liver, and which are derived either from the pneumogastric or the great sympathetic."

This is at once a condensed and correct description of the seat and nature of the affection. It will be observed that it is essentially a nervous disorder, and it differs, of course, in all important points from inflammation. The diagnostic symptoms are well marked, and are peculiarly important, inasmuch as the practice which is founded on them requires to be diametrically opposite to that which we are called upon to pursue in cases of inflammation.

Although the pains accompanying hepatalgia may be as intense as those of hepatitis, and, in many instances, perhaps more urgent, they are not constant, but are at the outset, and frequently also during the whole progress of the disorder, paroxysmal, affording in the interval a complete immunity from pain. The pathognomonic signs indicative of inflammatory action of the liver, are pyrexia, tumefaction, great tenderness in the hypochondrium, frequent and strong pulse, thirst, furred tongue, and vomiting, sometimes of a bilious, and, at other times, of a dark-coloured secretion, as the substance of the liver more or less partakes of the invading disease. The bowels are irregular in their action, the evacuations presenting a great variety of appearances, according as the biliary secretion is more or less affected; and the urine is scanty and high coloured. In hepatalgia, on the contrary, these signs are invariably wanting; there may exist, indeed, constant pain and tenderness over the region of the liver, increased to a certain degree by pressure, but manifest exacerbations, even in the worst cases, occur, which are sufficiently indicative of its paroxysmal character. The functions of the organ may proceed uninterruptedly as in its healthy condition. The tongue may be quite clean, or sometimes, in the centre, there may be a gentle creamy fur, and the urine is generally increased in quantity, and is of a lighter colour than ordinary: this I have found a characteristic symptom of many nervous disorders.

We have been contemplating the leading features of hepatalgia in its pure uncomplicated state, but it is comparatively rare that we meet with this condition, as it is generally associated with other decided manifestations of the neuralgic diathesis. However, it does occur, independently of these complications, and I regard the following case as a good example of pure isolated hepatalgia:—

The Rev. Mr. H—, a gentleman of active habits, and zealous in the performance of his clerical duties, was seized with a slight intermitting pain in the region of the right hypochondrium, which attacked him daily, on its accession, with something like periodic regularity. On the accession of the paroxysm, he was free even from a sensation of uneasiness (so perfect was the immunity in the intervals) until the succeeding attack. As his digestion was good, appetite unimpaired, and the pain comparatively trifling and of short duration, he did not deem it requisite to seek professional advice: and so the disorder was suffered to continue unalleviated, until it assumed a more formidable aspect. He now consulted a London practitioner, justly celebrated for the general correctness of his advice, who treated the case as one of chronic inflammation, and ordered a steady course of mild mercurial preparations. Under this system, the patient's sufferings were aggravated to a degree of intensity that quite alarmed him; and the more urgent they became, the more decided were the endeavours of the medical practitioner to subdue the "inflammatory" action, by getting the system as speedily as possible under the influence of the mercury. Finding he obtained no relief, and having a firm persuasion that a palpable aggravation of his suffering was occasioned by each dose of the medicine, he consulted me, and the following is a detail of the then state of the case:—The right hypochondrium was affected with constant pain, acute, and lancinating, which was greatly increased by slight—in fact, the gentlest—pressure; even the weight of the bed-clothes produced insupportable agony, so that he was invariably obliged to cast them off when he retired to rest, and in the day to sit in loose, unfastened garments.

During the first examination, having

engaged him in a conversation on an indifferent topic, thus diverting his attention from his malady, I pressed firmly upon the affected part, and so far from heightening the pain, it rather produced a temporary alleviation. Exacerbations generally occurred about two hours after dinner, and continued with great violence until, as I imagined, the food had passed from the duodenum, and ceased to excite by its action the morbid sensibility of the liver. The bowels were regular, and the motions healthy. The urine copious and limpid; and, in short, in the whole train of symptoms there was nothing indicative of inflammatory action, or of any disturbance of the hepatic functions, except the persistent pain. Having arrived at this conclusion, I immediately ordered a discontinuance of the mercury, placed my patient upon the plan hereafter to be detailed, and in the course of three or four days he became perfectly free from the attacks, and was enabled to resume his professional duties, which had hitherto, for some months, been completely abandoned. A period of upwards of two years has now elapsed, and there has been no return of the hepatic tic.

We will now consider a case of hepatalgia in its complicated form: that is, in its relation with peripheral neuralgia, in whatever part of the body its manifestations may occur: and this is by far the most common state in which we are called upon to observe it.

If there be, in the whole history of neuralgia, any isolated point of greater importance than another, or one that will more aid us in the discovery of its true proximate cause—the present hidden and mysterious bugbear of the practitioner—I would lay my finger here. To me, it is astonishing that authors, whose pen this fertile subject has inspired, have, as it were, with one consent, passed over in solemn silence the apparent fact of the manifold relations and dependencies assumed by this disorder. However, I will not anticipate, but proceed to submit a case which is rather a rule than an exception, similar manifestations presenting themselves in ninety cases out of a hundred, and which only require the commonest share of attention to be rendered apparent.

Mrs. H. F., a prematurely aged

woman, had suffered from facial neuralgia in its most violent form during a period of eight years. She had been treated by various medical practitioners of her native town, and had been dismissed from the Gloucester Infirmary as incurable. All the ramifications of the trifacial were affected; the lower and upper jaw, cheeks, forehead, eyes, and tongue. During a paroxysm, her face was thrown into contortions, and hard knots were formed in the course of the nerve. Tears flowed abundantly from the eyes, and the salivary glands poured forth their secretion as though she were in a state of profuse pyalism. Altogether she presented a most pitiable spectacle. The most important diagnostic symptom, and that for which this case has been principally detailed, remains to be related. On the cessation of the peripheral neuralgia, the liver was attacked with an almost insupportable pain; and when this viscus ceased to suffer from the metastatic hepatalgia, a transference of the morbid action invariably occurred in the branches of the trifacial. There were, in fact, alternations, transmitted from seat to seat, with unceasing regularity; but they never co-existed: so that the patient was enabled to foretell the locality of the anticipated paroxysm with unerring certainty. I do not venture to say that every case is so well marked as this, but I do assert, that in the great majority of cases we have more or less clear evidence of this alternate action.

I deem it unnecessary to swell this paper by accumulating evidence; more especially as I have published in this journal a lengthened correspondence containing the result of my experience on the present question; let it suffice for me to state, that in every case of local neuralgia, if the practitioner will search out patiently the symptoms as they arise, he will be surprised to find how strong a link in the associated chain of events will be supplied by the disorders of which we have spoken: and if the matter be new to his investigation, he will also discover that hepatalgia is an affection of much more frequent occurrence than has been admitted by our modern pathologists.

The treatment of hepatic colic, whether in its isolated or complicated form, is very simple, and merely requires the

combinations which are found to be effectual in other cases of neuralgia. Mercury, as in the *douloureux*, heightens the affection, increases the general irritability, and renders the system universally more obnoxious to the incursions of the morbid nervous sensibility. Carbonate of iron—the rage of the day—is, if possible, even more destructively pernicious; and I would ask, if my assertions be correct of the dependencies of the disorder (and they may easily be put to the test,) whether or not the action of a powerful tonic is likely to prove beneficial in any one of its earlier stages? Yet it has been administered with reckless daring in all the phases and all the complications of neuralgia. Gentle purgatives, combined with colchicum, ipecacuanha, and hyoscyamus, will seldom fail to work a speedy cure: and if the constitution have suffered from protracted unmitigated pain, alkaline vegetable tonics will effect that which we might in vain expect from the rough insoluble mineral preparations.

Parliament Street, Whitehall,
March 10, 1845.

OBSERVATIONS ON DIGESTION AND DIET.

By DR. WILKINSON, Bath.

THE grand result of digestion is the formation of the constituent parts of blood which principally consists of albumen, and as it is admitted that the nutritious quality of all food, whether vegetable or animal, is in proportion to the quantity of albumen contained, it must appear evident that the agent employed for its separation from the general mass must possess the property of dissolving the albumen. It is well known to chymical inquirers that this is readily effected by an alkali, whilst it is insoluble in acids or alcohol, or even in cold or boiling water. Liebig, in his admirable work on Organic Chymistry, considers one of the principal agencies of saliva is from its entangling, during mastication, atmospheric air, and that the oxygenous portion enters into combination, while the other constituent part of the atmosphere, viz. nitrogen, is given out through the skin and lungs. He further says, that the longer digestion continues, that is, the greater

the resistance offered to the solvent action by the food, the more saliva, and consequently the more air, enters the stomach. Thus he considers rumination, in certain graminivorous animals, has plainly for one object a renewed and repeated introduction of oxygen; for a more minute mechanical division of the food only shortens the time for solution. As for the gastric fluid, he thinks that it possesses a property of transforming those constituents of the food, which by themselves are insoluble in water, in virtue of a new grouping of their atoms, the property of dissolving in that fluid. He observes, that during digestion the gastric juice, when separated, is found to contain a free mineral acid, the presence of which checks all further change. That the food is rendered soluble quite independent of the vitality of the digestive organs, has been proved by a number of the most beautiful experiments.

It is, I presume, admitted by physiologists, that the secretion of the gastric fluid, as well as all other secretions, results from the agency of the principle of vitality, and, when the secretion is effected, the future changes are chymical. Liebig entertains an idea that, with respect to the gastric fluid, it possesses some unknown power of effecting a transformation in the constituent parts of the substance it is destined to act upon, without any apparent material communication. I am not acquainted with any analogical experiments in either synthetical or analytical chymistry to support such an opinion.

The illustrious Newton states, in the 3d book of his admirable *Principia*, the following hypothesis:—“*Causas rerum naturalium non plures admitti debere, quàm quæ et vera sint et eorum phenomenon explicandis sufficiunt*.”—and this hypothesis he thus illustrates—“*Natura enim simplex est et verum causis superfluis non luxuriat*.” With respect to Liebig, no person can appreciate more highly his chymical talents than I do; yet it appears to me that, in its application to many physiological operations, he has involved himself in difficulties which he might have avoided, by adopting that simplicity recommended by the great British philosopher in the above quotation. It must, however, be acknowledged that we owe much to this celebrated chym-

mist; and the few objections stated by Dr. Bostock and others may be compared to those maculæ (or spots) on the sun's surface, visible only to the telescopic observer, and not accompanied by any sensible diminution of its splendour.

In ruminating animals, the muscular structure of the œsophagus is admirably calculated for that tortuous motion remarked in the throat whilst chewing the cud; and the cause is very observable by dissection of this part. After being exposed to a gentle boiling heat in water, two rows of muscular fibres, resembling a double corkscrew, are unfolded, and, when in action, may be compared to those wells which have two buckets, the descent of the one being necessary for the ascent of the other. It is well known to observing agriculturalists that if the cow or the sheep should by misfortune drop the cud out of the mouth, it cannot raise a fresh portion by its own natural power; as the descent into the third stomach of that portion which has been a second time masticated is necessary to the elevation of a corresponding mass from the second stomach. When such is the case, the animal is remarked to pine, to lose its appetite, in consequence of the digestive process being interrupted, and in most cases it is found necessary to kill the animal. Nature, for the protection of the cud, has rendered the upper part of the tongue, near the throat, of a spiculated roughness, the spiculæ so arranged as to prevent any easy loss of the cud. In Switzerland, attempts have been made to substitute an artificial cud, made of boiled potatoes and sugar, but I believe without success. Upon this interesting physiological principle I have conversed with many eminent graziers, and who all concur in opinion that the greatest attention is necessary to prevent the dropping of the cud, particularly guarding against a too watery condition of food. The accident is soon rendered apparent by the animal no longer taking its usual food, no longer reposing on the ground for the purpose of rumination. During the period the animal is fed solely by milk, there is no ruminating process: in such cases the second and third stomachs are entirely inactive, and the digestive product from the first stomach is conveyed by a tube to the fourth. For

the illustration of this, my learned friend, Professor Owen, informed me that in the Museum of the College of Company they have specimens of this tube in the stomach of a milch calf. As soon as the animal commences with graminivorous food, the tube becomes obliterated, and its new stimulus on the second and third stomachs gives rise to the ruminating process.

When chyle has been intermixed with the biliary and pancreatic secretions, and highly magnified, there appears round each globule a greenish areola, which by gently drying assumes a reddish tint. May we not attribute to the secretion of the liver a four-fold action—1st. A secretion of soda to convert the chyme into chyle; 2d. Imparting the colouring rudiment to the globular particles; 3d. From its bitter principle, or picromel, acting as an antiseptic to the intestinal contents; and, 4th. By its stimulus, producing that peristaltic motion necessary for its ultimate evolution.

It is a law in nature, that two actions cannot go on in the same portion of matter at the same time. If the secretion should be deficient, or the stomach surcharged by its contents, the proper separation of the albumen is prevented, fermentation takes place, and carbonic gases principally are evolved. Thus sheep feeding in rich clover pastures frequently overload the first stomach, so as to prevent the communication into the second; the food too long retained ferments, and the animal becomes painfully distended by the developed gases, as to frequently require the operation of houghing. Sir E. Home states that liquids drunk by the animal pass at once into the second stomach, the entrance, at that period, into the first being closed. In the months of August and September, graminivorous animals, feeding on pastures that lie on the marl which covers some of the beds of the blue lias, are subject to that dreadful disease called scouring, although hay made from the same grass is not injurious. It generally appears after the first cutting. The loss sustained by this complaint, in the county of Somerset, has been stated to exceed £60,000 per annum. At the request of some members of the West of England Society, I was induced to examine this grass, and I ascertained that the injury arises from the formation of

acetic acid. This combines with the soda in the stomach. The result is a purging salt, and the food by the destruction of its solvent rendered inefficient; after being cut and dried, the acid is volatilized, and the hay is good.

Upon this principle are easily explained the thin and emaciated constitutions resulting from an indulgence in acids. It is well known that many young persons sacrifice their health from a dread of corpulency, by taking lemon juice, which, by its agency, destroys the solvent power of the soda; and what food is taken into the stomach passes off in an undigested state, the animal matter becomes rancid and putrid, the chyle and all the secretions in the same proportion deteriorated. We know that life can only be supported by matter which has constituted a part of an organized being; how these varied changes are effected by its agency, our limited powers cannot comprehend. May we indulge an opinion, that all nutrient food contains a living principle, which is added to the general stock, by which we are enabled to explain their growth? The late experiments of Prevost and Dutrochet have evinced, that when the fabric of an organized being is resolved into its simple constituent parts, each part has a globular appearance, possessing powers of motion, forming those monads which constitute the last link in the chain of organic life. The process of digestion is by this hypothesis considered as the power of separating these monads from their state of combination in the food taken, and assimilation is the deposition of them to their destined purposes. The albuminous globule, as well as that of the red particle of blood, is not spherical, but bears some resemblance in figure to that of the monas termo; and a further cultivation of this interesting subject would probably lead to an explanation of the powers of reproduction, and of many other important phenomena of nature. Thus it is well known to professional gentlemen that many organs in the animal body, when in a morbid state, are subject to become the repository of worms; their existence is not considered to constitute the primitive disease, but as the resulting product. They assume different characters, according to the nidus where they appear

to be formed: certainly most of those found in the human body are not observed in any other part of animated nature. Thus the tapeworm in man is jointed; in sheep and fish it more resembles a tape. Pallas and Bloch have found the tapeworm in a fœtus; and I had an opportunity in Geneva of seeing a tapeworm, 7 feet long, in a fœtus of six months. The mother being accidentally killed, gave rise to the examination. Not only in the intestinal canal, but in almost every part of the human frame, worms have been found: whence they originate is a question extremely difficult to answer; but I presume the difficulty would be increased by attempting an explanation on the Aristotelian idea of spontaneous generation. Although Blumenbach considered each articulation as a distinct worm; but Rndolphi and Bremser, who have paid great attention to this subject, deem it as one animal, and observe that the head has four trunks or suckers. I had once an excellent opportunity of seeing an animal passed off by a hospital patient, resembling a large leech in form but not in colour, about 4 or 5 inches in length. It was preserved in a covered vessel till the following morning, when the length was increased to many feet, and with all the character of the tapeworm, and which on examination proved to be the case. This remarkable circumstance throws great light upon the probable economy of this surprising animal. The joints do not commence near the part supposed to be the head, but a few inches below, leading to a supposition that in the living state it is an intestinal arrangement, folded in the body of the animal, in length only a few inches.

[To be continued.]

ANALYSES AND NOTICES OF BOOKS.

“L’auteur se tue à allonger ce que le lecteur se tue à abrégé.”—D’ALEMBERT.

Observations on Aneurism. Selected from the works of the principal writers on that disease. Translated and edited by JOHN E. ERICHSEN, Esq. (Printed for the Sydenham Society.)

THE success of the Sydenham Society, which has far exceeded the most san-

guine hopes that were entertained by its founders, is both a cheering evidence of the improved state of the literary condition of the profession, and a good augury for its future welfare; more especially so when, in looking over the list of the subscribers of the Society, we find that so large a number of the junior members of the profession have enrolled their names. The wide diffusion in an elegant form of the standard works of the great masters of our art, whether ancient or modern, cannot but be attended with the most beneficial results. Important, however, as the reprint of standard English works, or the translation of complete editions of the Greek, Latin, or Arabic authors may be, there is yet another form of publication that is, in our opinion, equally valuable, namely, selections from the works of ancient and modern writers on some of the more interesting medical and surgical diseases, by which means many of the most valuable essays that lay entombed in the old Thesauri, or in the periodicals of the day, and that are altogether beyond the reach of the mass of the profession, may be brought to light, and rendered accessible to every one. The volume now before us is the first that has been published in accordance with this plan, and we trust that it will not be the last. The manner in which Mr. Erichsen has executed the very difficult task that has been entrusted to him is most creditable to his talents and industry, and he has succeeded in producing a volume that will not only be a standard work of reference on the very important subject of aneurism to the scientific surgeon, but that will be of very great interest and utility to the profession at large. As the work is necessarily by this time in the hands of our readers, we will merely content ourselves with directing attention to the very complete bibliography that is appended to it, being a catalogue raisonnée of nearly two hundred essays and treatises, the preparation of which alone must have been a task entailing no slight labour, and the execution of which reflects much credit upon the taste, judgment, and acquirements of the author. We do not think that the Society can do better than to take the present volume as a model for the publication from time to time of similar *collectanea* on other important medical

or surgical subjects; as, for instance, hernia, lithotomy, hæmorrhage, injuries of the head, diseases of the nervous system, &c.

The London Medical Directory. 1845.
Containing the name, address, qualifications, official appointments, honorary distinctions, and literary productions, of every physician, surgeon, and general practitioner, resident in London. 12mo. pp. 180. Mitchell, Red Lion Court.

This is a considerably smaller volume than we had anticipated; we must say that our brethren have not abused the opportunity which the editors of the Medical Directory gave them of drawing forth their works to the best advantage. The list is, indeed, most creditable to the members of the medical profession. There are, unquestionably, but few drones in the hive; and, if all who occupy the foremost place, in regard to position and emolument, have not done the most to deserve them, still it is gratifying to observe that many who have worked hard have achieved eminence in consequence of that hard work we would fain believe, although we have known some guilty of the heresy of maintaining that the distinction came *in spite* of it. We have said that the volume was smaller than we expected it would have been; we confidently anticipate that next year it will have enlarged its dimensions considerably. The work is, in fact, a medical directory in more senses than one; it is not merely a list of the names and residences, but an index of the writings of the men now living and exercising medicine within the metropolis, and its precincts; and we venture to suggest to the editors the advantages that would attend upon a considerable extension of the work in the latter direction especially. One of the very useful books of reference in the present day is the *Lexicon of Living Authors* of Callisen, published at Copenhagen, and now extending to many volumes. The London Medical Directory, by giving the titles of each writer's papers in full, and an exact reference to its place of publication, would accomplish, in regard to the medical men of the metropolis, that which Callisen proposed to himself to effect with reference to the wider field

of Europe. Of the utility of such a catalogue there can be no doubt. This portion of the scheme was probably viewed by the proprietors of the London Medical Directory as only subsidiary or subordinate; extended, we believe that it will have the effect of giving the work a *permanent* interest. Meantime, and for what is effected, we think the thanks of the profession are due to the editors of the London Medical Directory. The publication of this volume marks an epoch in our professional annals; it is the first time that we have had a List of our own, like the army list, the navy list, and the law list; and, so far as we can judge, the list is wonderfully complete; omissions we should imagine there must necessarily be, although, with a solitary exception, we have looked for them in vain. We beg to recommend this very useful volume, the London Medical Directory, to all our friends, both of the metropolis and the country.

—

The Structure of the Lungs; being the Warneford Prize Essay for the Year 1844. By JOHN MOORE. 8vo. pp. 106.

THIS essay is written, the author informs us, "for the purpose of showing, by the consideration of the 'structure and physiology of the lungs,' the 'wisdom, power, and goodness of God as revealed and declared in Holy Writ;' and though the conformation and office of each and every portion of the human frame be capable of affording proofs of these, there can be none better calculated to evince them than that whose special function it is to cleanse and vitalize the blood, on the good quality of which depend the maintenance and the due performance of all the other functions of the body." p. 3.

The author treats, first, of the variable structure of the respiratory apparatus in different classes of animals; the characteristics of the human lungs, their anatomical relation, development; the phenomena of respiration. The second part of the Essay, occupying about thirty pages, is devoted to natural theology, and is well suited to the Christian student.

Five lithographic plates are appended in elucidation of the pulmonic textures.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medice tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

DEATH FROM STARVATION.

IT appears from the statistical returns, that the average yearly mortality from starvation in this country amounts to 145. In many cases referred to this head, death was accelerated by exposure to cold and inclement weather, and by want of bodily raiment. Several of the wretched beings had been subjects of intemperance and disease; a few, to our nation's shame be it told, were suffered to pine and die in the workhouse, from not having the necessities of life provided by the officers of the poor law. No one will for a moment suppose that any of the individuals who thus perished through lack of food, could avert their fate,—certainly not. It was their poverty, and not their will, which consigned them to the dark and silent grave.

Not so the hapless attorney over whose corpse a coroner's jury was empannelled no later than Friday last. The deceased, although surrounded by plenty during his sojourn here on earth, was allowed to die like a dog, from inanition through starvation—a victim to one of the most contemptible systems of quackery ever palmed upon weak, ignorant, or credulous man.

Let us briefly consider the facts of the case. A patient, aged 29, is laid up with fever brought on by influenza, having shortly before been in very good health. Although *quite in his right senses*, and not betraying any thing strange in his manner, he sends for a homœopathic doctor, who attends him till near dissolution. By way of treatment, powders are administered at dif-

ferent times—minute doses of sugar of milk; for the most refined act of chemistry, while it can reveal the presence of the 500,000th part of a grain of arsenic, has failed to detect aught in the globules of homœopathy save sugar of milk. The regimen enjoined is water—nothing else; and during ten consecutive days, when in a weak and sinking state, his lips remained sealed to every thing but cold water. Eventually it was qualified by a fragment of toast, but the latter he dared not touch.

The homœopathic doctor, on being questioned by an anxious friend as to the nature of the patient's malady, observed that "his complaint was altogether very simple." It did not prove so in the sequel. By the eleventh day extensive hæmorrhage from the bowels supervened; and when the sick-nurse begged permission to give the man, prostrate by starvation and loss of blood, a little nourishment, the doctor condescendingly said, "she might give him a teaspoonful of beef-tea or two at that time." On swallowing this he exclaimed, "Oh, does it not relish?" He had previously got by stealth some thin barley water, which he equally relished, but requested that the jug might be hidden, lest the doctor should see it.

The friends of the patient, on being apprised of his alarming condition at the above period, called in a regular physician of eminence. This gentleman, on examining the patient, found his head free from fever or heat. The chest "was tolerably healthy; there was no active disease of the heart or thoracic viscera. The abdomen was flat, and so much drawn back towards the spine, that it would hold water like a small basin. The tongue was very clean; in fact, most unusually so. His pulse was about 88 or 90, but was extremely feeble. Witness found a piece

of white rag in his mouth, which he chewed to excite the salivary glands, and relieve his thirst. There was no ulceration of his throat, and his skin was rather below the ordinary temperature. His feet were rather cold. There was hæmorrhage from the bowels, and a great quantity of blood had been lost." . . . "He thought his state one of extreme danger." A general practitioner, whose co-operation had been required at the same time, corroborated the above testimony, and stated that the bleeding did not cease till a short time before the patient died, namely, the fourth day of their attendance.

The blood, which kept oozing away, seemed attenuated, deficient in fibrin, precisely as in the instance of purpura hæmorrhagica. On cadaveric inspection the brain presented some scarlet puncta; the chest was fully formed, but there were adhesions of both lungs, and about eight firm solid tubercles, about the size of peas, in a perfectly quiescent state, distributed through the upper part of each lung. There were ulcers in the lower part of the ileum, and in the cæcum. No trace of fat could be found, except about the heart. The medical men arrived at the conclusion, that death had been caused by hæmorrhage.

The jury, while framing their verdict accordingly, could not "refrain from expressing the strongest feelings of disgust and indignation at hearing it proved by the testimony of the nurses that the afflicted gentleman had been cruelly exposed to a system of starvation while in the state of the most extreme debility, during at least ten days previous to his death, he having, during that long time, been allowed nothing but cold water, by the advice of his medical attendant." The Coroner fully concurred in the verdict.

In this course they were fully justi-

fied, inasmuch as the Registrar-General has lately recommended that juries be instructed to announce with greater minuteness than at present the cause of death; "recording more in detail the nature of the injury, and the *circumstances under which it happened*.*"

The above disclosure will, we trust, demonstrate to the public the danger and absurdity of homœopathic quackery. Nothing could have been fairer or more unbiassed than the conduct of the medical men on this occasion. They confined themselves to a bare narrative of facts, without promulgating any opinion. Upon this statement the jury rested their verdict. The expression of censure is a distinct proposition, deduced from the evidence of the nurses, and is thoroughly borne out.

We think that, under proper management, the unfortunate gentleman would have had a reasonable chance of recovery. The amount of organic disease was inconsiderable. There were, it is true, ulcers on the surface of the bowel. But are ulcers in that situation necessarily mortal? by no means. Every practitioner in the habit of frequenting the dead-house must have witnessed examples of cicatrices upon the mucous membrane, denoting the pre-existence of ulceration, where the subject died of some other malady. The presence of a few isolated dormant tubercles in the lungs is of trivial import. Under such circumstances the respiratory function might have gone on unimpaired for a long series of years, taking into account that all the other viscera were sound.

It was assuredly the bounden duty of the medical attendant to have supported the patient's strength by bland nutriment, instead of letting him sink from inanition. In such cases, says Dr. Abercrombie, "much depends upon

diet, and the greatest benefit is often obtained from a regimen restricted entirely to farinaceous articles and milk*."

MEDICAL MISSIONARY SOCIETY OF EDINBURGH.

OUR attention has been called to a very laudable undertaking—the Medical Missionary Society of Edinburgh. The objects of this association are to circulate information on the subject of Medical Missions, to aid other institutions engaged in the same good work, and to render assistance at Missionary stations to as many professional agents as the funds placed at its disposal will permit. All persons contributing not less than five shillings a year are members. Through the united instrumentality of Dr. Parker, of Canton, and the late Dr. Abercrombie, a committee was formed, whence the Society originated. There are at present in connexion with the Medical Missionary Society in China, three medical men, constantly employed in giving their services to all applicants, irrespective of rank, age, or sex; two others are resident in Persia. Dr. Beilby is President, and the Rev. Dr. Chalmers, with Dr. Alison, are Vice-Presidents.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Tuesday, March 11th, 1845.

DR. CHAMBERS, President, in the Chair.

THE Society was crowded to excess this evening, in consequence of the installation of the newly elected President.

Dr. Chambers on taking the Chair, briefly addressed the Meeting. He thanked them most sincerely for the honour they had done him in electing him their President, an honour which he regarded as the greater, inasmuch as he had really done nothing for the Society, he therefore viewed it as the result of personal esteem and regard.

Absence from the Society, however, he could assure them was the result of the pressure of his ordinary occupations, occupations from which no one who had once embarked in them could shrink. The pressure of these occupations had weighed upon a constitution never very robust, and had produced a series of formidable attacks which had precluded him from joining in the trans-

* Sixth Annual Report, p. 25.

* Diseases of the Abdominal Viscera, p. 283.

actions of those literary and professional associations from which he might have experienced both satisfaction and improvement. He requested the indulgence of the Society in any deficiency he might, as their President, exhibit, but assured them that he never could be deficient in his desire to benefit the Society.

On the Pulsating Tumors of Bone, with the account of a case in which a ligature was placed around the common iliac artery. By EDWARD STANLEY, F.R.S. Surgeon to St. Bartholomew's Hospital.

THE author remarks that there are three distinct sources of pulsation in the tumors of bone—1, the proximity of the tumor to a large artery; 2, the development of blood-vessels and blood-cells, constituting a sort of erectile tissue within the tumor; 3, the enlargement of the arteries of the bone in which the tumor has arisen. Proximity to a large artery is the most frequent source of pulsation in these tumors, of which six examples are brought forward. Three occurred at St. Bartholomew's Hospital. In one of them, an encephaloid tumor originating in the humerus, the ligature of the subclavian was recommended, but not assented to by the patient. In another, it was agreed in consultation that sufficient ground existed for believing the tumor to be a popliteal aneurism, and accordingly the femoral artery was tied in the middle of the thigh. The tumor consisted of a compound of soft fibrous and dense osseous tissue, the latter situated deeply and extending around the femur, in which it appeared to have originated. Of the other three cases, two were communicated by Mr. Hodgson, of Birmingham, and the third by Mr. Lawrence. The latter is already recorded in the 17th volume of the Transactions of the Society. There are six examples of pulsating tumors, differing in their nature and originating in different bones, but agreeing in the circumstance that no other source of pulsation was discoverable in them than the contiguity of large arteries. To the same class of cases the author considers that the important one related by Mr. Guthrie belongs, in which a medullary tumor about as large as an adult head, situated upon the right nates of a female, presented so decidedly the characters of aneurism, that it was believed to be so by Sir Astley Cooper and other experienced surgeons who were consulted upon the case, and accordingly a ligature was placed around the common iliac artery.

On the subject of pulsation in the tumors of bone dependent on the development of blood-vessels and blood-cells, forming a sort of erectile tissue within the tumor, Mr. Stanley remarks, that in the case of recent occurrence in St. Bartholomew's Hospital,

there certainly was a structure capable of enlargement by the distension of its vessels and cells; and assuming these to have been continuous with the surrounding arteries, the rush of blood into this structure might give to the whole mass a pulsation resembling that of aneurism. Two cases are related, in which the pulsation of the tumor was ascribed to a similar cause. In one communicated to the author by Mr. John Lawrence, Jun. the tumor, originating in the upper part of the femur, was more of a gelatinous than encephaloid character, and its gelatinous tissue formed more than one half its bulk. The other, which was furnished by Mr. Iuke, of the London Hospital, was a tumor of the lower part of the femur, and, in consequence of suspicion of aneurism, the femoral artery was tied. The limb was subsequently amputated, when the tumor was found to consist of cells of varying size, some of the largest being about an inch in diameter, and they were filled with blood.

Of pulsation in the tumor of bone dependent on the enlargement of the arteries of the osseous tissue, several cases are referred to; one related by Dupuytren, the others by Pelletan.

One circumstance in the history of these different forms of pulsating tumor is especially noticed by the author, as it appears to have a material influence on the production of pulsation in them,—this is, the density and resistance of the immediate investments of the tumor. He adds, that it may be doubted whether any of these tumors would pulsate without the resistance derived in one or other direction from the bone or its coverings. A tumor originating in soft parts, and unconnected with any bone, but situated close to a large artery, and confined within resisting structures, and thus approximating in its conditions to the pulsating tumor of bone, may, like it, pulsate in a manner to be mistaken for aneurism. An example is given of a man admitted into St. Bartholomew's Hospital, under the care of Mr. Earle, with a pulsating tumor below the left clavicle, which presented all the appearances of aneurism, and accordingly a ligature was placed around the subclavian artery. The tumor subsided sufficiently to confirm the opinion entertained of its nature, and the patient was discharged. Six years afterwards he was again admitted with general derangement of the health, from which he sunk. On dissection, the axillary artery presented no indication of having been the seat of aneurism. Immediately behind the artery was a solid tumor, which had originated in the sheath of a large nerve.

After some observations tending to show the little value to be attached to the presence of bellows-sound in the diagnosis between aneurism and the pulsating tumor of bone,

the author proceeds to relate the case of pulsating tumor of the ilium which has recently occurred in St. Bartholomew's Hospital, in which a ligature was placed around the common iliac artery. The patient, a man, aged 42, had on the inner side of the right upper arm, a tumor about the size of a small orange, very loosely connected with the surrounding structures, free from pain, and without pulsation. This tumor was first observed about ten years ago, and during the last three years it had ceased to grow. The pulsating tumor of the pelvis had its chief attachment to the left ilium, and projected from both surfaces of the bone. It reached downwards to Poupart's ligament, and to the extent of about three inches into the abdomen. It felt moderately firm, and a little below the crista, near the anterior superior spine, a small moveable piece of bone was discovered apparently involved in the tumor. Every where within reach of the fingers the tumor pulsated, not with a thrill or vibration, but with the deep heavy beat of aneurism. By the ear resting against the abdominal parietes, a bellows-sound was plainly recognised. After a minute description of the local features and constitutional phenomena of the disease, the author observes, that in deciding on the nature and treatment of the case, the following points were involved—was this pulsating tumor an aneurism? and if so, from what artery had it arisen; or was it one of the pulsating tumors of bone? He then states the arguments which, in consultation, led to a preponderance of opinion in favour of this tumor being an aneurism. In the uncertainty respecting the origin of the supposed aneurism from the external or internal iliac artery, the decision would obviously be that the common iliac should be tied, and the man having decidedly expressed his feeling in favour of submitting to the operation, the author considered it his duty to undertake it. The operation was performed on Monday, the 27th of Jan. The case proceeded favourably to the middle of the second day, when symptoms of peritonitis ensued, and he sunk on the morning of the third day from the operation. On examining the body, the effects of peritonitis were observed in the deeper parts and left side of the abdomen. In the wall of the left ventricle of the heart there was a medullary tumor about the size of a filbert. Medullary matter was found in the bronchial glands, and a few deposits of the same kind in the lungs. A minute description is given of the tumor in the pelvis, which was connected with the ilium, and composed of a spongy tissue with cells and convoluted vessels distributed through it. The tumor in the arm, which had all the marks of an innocent structure, was found, to the surprise of the author,

identical in structure with the tumor in the pelvis.

This paper is concluded by some remarks on the operation of tying the common iliac, or the external iliac near its origin, tending to show that with the least risk of injury to the peritoneum, the readiest mode of reaching these vessels must be by an incision through the posterior part of the abdominal parietes.

Mr. Toynbee briefly referred to a case he had lately dissected of a young man who had died of consumption at the age of 19. The patient had a pulsating tumor of bone differing from Mr. Stanley's cases, inasmuch as it was almost entirely composed of blood-vessels, and contained no cells or other structure. It was situated at the point of ossification of the parietal bones.

Mr. Ferguson regarded the paper of Mr. Stanley with much interest. It shewed the great difficulty which experienced surgeons might encounter in deciding on the true nature of certain kinds of tumors connected with the pelvic region. He had seen several cases similar to those brought under notice by the paper. Two of these cases had been under the care of Mr. Syme, of Edinburgh, and illustrated the diagnosis of these cases, even to experienced and able surgeons. These cases occurred during his (Mr. Ferguson's) connection with the Royal Infirmary, and he had consequently had an opportunity of seeing them. Mr. Syme had published them in his Clinical Reports. In one of these cases there was a swelling in the situation of the external iliac artery, which was considered to be aneurismal; other surgeons, however, were of a different opinion. Mr. Syme, however, acting chiefly on his own responsibility, determined upon placing a ligature high up on the external iliac, or on the common iliac artery, as might seem advisable. On completing the incisions through the abdominal parietes, it was discovered that the tumor was not an aneurism; it was nevertheless removed, and the patient sunk a few days after the operation. It was then discovered that tumors of a similar kind were situated in various parts along the course of the chief arterial vessels; they were smaller in size than that removed, but it was evident they owed any pulsation they possessed to their connection with the arteries. In a second case, in which a tumor was also situated in the course of the external iliac, much difference of opinion existed amongst the most distinguished surgeons of Edinburgh respecting its true nature. Eventually a ligature was placed round the common iliac artery. The patient died, and the tumor was found to be aneurismal. Another case, which had come under the observation of the speaker, resembled in many

points the cases mentioned by Mr. Stanley. The pulsation and the *bruits*, said to be diagnostic of aneurism, were present; he, however, refused to operate. He was led to this determination from having recently become acquainted with Mr. Guthrie's case, to which reference had been made in the paper. After death the tumor was found to be very similar to the cases mentioned in the paper. The tumor was prominent in the pelvis both internally and externally, and the os innominatum was completely destroyed. The tumor was composed chiefly of medullary matter, clots of blood, and spiculæ. Mr. Nicol, of Inverness, about the time of the occurrence of these cases, had treated a tumor connected with the upper part of the shoulder-bones, supposing it to be aneurismal.

The case was similar to one related by Mr. Luke, inasmuch as the tumor had resulted from an injury. A ligature was placed round the subclavian. At first the operation appeared successful, but the patient soon died, and the tumor was found to be malignant.

ADDRESS DELIVERED AT THE ANNIVERSARY MEETING, HELD MARCH 1ST, 1845, BY EDWARD STANLEY, ESQ. F.R.S. PRESIDENT OF THE SOCIETY.

Gentlemen,—It appears to be an expected duty of your President, now almost sanctioned by time, that he should, at this meeting, briefly set forth a history of the Society's progress during the preceding year, and there is an obvious good in this; it becomes the means of informing the Fellows, at stated periods, of the condition of the Society—whether it is generally prosperous or otherwise, whether, in all its arrangements, the Society is working fully and effectively for its objects of advancing and diffusing medical science, and of promoting, as far as it can, the amicable relations of its associates; and if there be departments of the Society admitting of improvement, this annual retrospect affords to the Fellows the opportunity of considering in what directions it can best be made.

Our new associates in the preceding year amount to thirty-two, among whom I notice with peculiar pleasure Professor Thomas D. Müller, the distinguished surgeon of Philadelphia, who, in offering himself to our ballot, and contributing money to our funds, has afforded substantial proof of the estimation in which the Medico-Chirurgical Society is held by our transatlantic brethren.

We have to regret that, during the preceding year, the following names have been removed from our list—Dr. Sutherland, William Annandale, Esq., Dr. Billiug, and Thomas Copeland, Esq.

Our total number of Fellows, exclusive of Honorary Associates, is at this time above

five hundred; and of these we are to remember that many reside in the provinces, and consequently derive no other advantage from the Society than a participation in the good name it bears.

Our library report corresponds with the general prosperity of the Society; we have added to our collection, during the preceding year, 203 works, of which 77 were by presentation, and the remainder by purchase. Our reading-room, now stored with all the British and foreign scientific journals of value, is proved, by its usefulness to the Fellows, to be an important feature in our arrangements.

Our ordinary meetings, it affords me much pleasure to state, have, during the preceding year, been well attended, bringing together from seventy to a hundred of our Fellows, with numerous visitors, many of whom have come from the provinces, and from foreign countries.

Our twenty-seventh volume of papers, equalling its predecessors in bulk, is, I confidently believe, regarded by the profession as not inferior to them in value.

Here I conclude the enumeration of the principal incidents furnishing criteria of the condition of the Society, and pass to another portion of my report, which will be regarded with feelings of a different kind.

We have had the misfortune to lose by death, during the preceding year, the following Associates:—Dr. Dalton, Sir Henry Hallford, Dr. Barlow, of Bath, Dr. Hope, of Edinburgh, Dr. Home, of Edinburgh, Sir Isaac Wilson, of Bath, and Mr. Tupper, of London.

It is well known to be a custom which has been long observed in the scientific societies of the Continent, that, at stated periods, the merits and the virtues of deceased associates should be duly commemorated. And of late years an expectation seems to have arisen in the minds of the Fellows of this Society to receive something of the same kind from their President at these annual meetings. But in assigning such a task to the President, you will, I venture to say, sometimes place him in a difficult and delicate position, for, in the course of events, it will happen that many of our departed Fellows have been most estimable individuals, both in professional and private life, and yet they may not have left behind them such durable monuments of professional skill and knowledge as would constitute a befitting eulogy to be pronounced before the members of a learned Society; with due consideration, therefore, I beg you will receive the few matters of information I have been able to collect respecting the character and conduct of our departed associates in the preceding year.

To inform you what the chemical philo-

sopher has done for the advance of his science requires, for justice to be done to the subject, that it should be treated by a chemist. I have learned just enough of the subject to know that in every country where science is cultivated, the title of philosopher, in its highest and largest sense, is awarded to our departed honorary associate Dalton, in acknowledgment of his labours and discoveries in chemical and physical science, among which stands out foremost his development of the theory of definite proportions—the foundation of modern chemical philosophy.

An instance is here presented to us of the difficulty with which new truths are often appreciated even by minds well prepared to receive them. Dr. Thomson tells us, that shortly after the promulgation of Dalton's views, happening to dine at the Royal Society Club, every member having left the room except Sir Humphry Davy, Dr. Wollaston, and himself, they occupied an hour and a half in conversation about the atomic theory, in order to convince Davy of the inaccuracy of the opinions he had formed of it; but, so far from changing his opinions, he went away, if possible, more prejudiced against it than ever; and that soon afterwards, Davy meeting Mr. Davies Gilbert, amused him with a caricature description of the atomic theory, which he exhibited in so ridiculous a light, that Mr. Gilbert declared he was astonished how any man of sense or science could be taken in with such a tissue of absurdities. But Davy, at no distant period, became so complete a convert to the new views, that we find him the warm eulogist of Dalton, in delivering to him, at the Royal Society, the first of the Royal medals awarded for discoveries, or useful labours in any department of science.

Originality and clearness of thought, ingenuity of explanation, capacity for labour, and power of generalization, were in a remarkable degree united in Dalton. But the beauty of his mind was most conspicuous in the sincerity and earnestness of his devotion to science, independent of worldly considerations; and in the early part of his career, with a very small share of worldly prosperity—for it is known that he resorted to the lowly occupation of teaching others to write as the means of providing his own subsistence, and, at a later period, gave lessons in mathematics and natural philosophy at the charge of eighteenpence an hour. And it was at the time of fulfilling these humble duties that Dalton commenced those investigations which led to the discovery of the laws upon which the whole system of modern chemistry is based. Following him through a later period of his career, we find him displaying the same greatness of character in the little anxiety he manifested lest others

should outstrip him in the race of discovery. It appears that the simple and happy idea from which the atomic theory originated first occurred to the mind of Dalton in the course of his researches on the solubility of different gases in water, which were published in the Transactions of the Manchester Society for 1803. But not until 1808 did he publish his new views in the first volume of his *Chemical Philosophy*, and not until twenty more years had elapsed did he publish the completion of his views in the third volume of the same work, a great part of which had been printed more than ten years.

Dr. Dalton occasionally directed his mind to physiological subjects, and displayed in these the same turn for experimental inquiry, and originality of thought, as in the subjects of chemical and physical science. His papers on physiological subjects were published in the *Memoirs of the Literary and Scientific Society of Manchester*. They are, an account of a peculiarity of vision in his own person, under the title of *Extraordinary Facts relating to the Vision of Colours*; also papers on respiration and animal heat; on the mechanical effects of atmospheric pressure on the animal frame; and on the quantity and chemical elements of food compared with the secretions in a healthy person, founded upon a series of experiments which were chiefly made upon himself. And it especially deserves to be noticed that in the last-mentioned he commenced the line of investigation which has been recently pursued by Professor Liebig, and, I am authorized to add, without his being aware of the previous observations of Dalton on the same subject.

The account of the discovery of the peculiarity of vision in his own person is thus given by Dalton:—"I have often seriously asked a person whether a flower was blue or pink, but was generally considered to be in jest. Notwithstanding this, I was never convinced of a peculiarity in my vision till I accidentally observed the colours of the flower of the geranium zonale by candle-light. The flower was pink, but it appeared to me almost an exact sky-blue by day; in candle-light, however, it was astonishingly changed, not having then any blue tint, but being what I called red. Not then doubting but that the change of colour would be equal to all, I requested some of my friends to observe the phenomenon, when I was surprised to find they all agreed that the colour was not materially different from what it was by daylight, except my brother, who saw it in the same light as myself. This observation clearly proved that my vision was not like that of other persons." * * "Reflecting on these facts," continues Dr. Dalton, "it appears almost beyond a doubt that one of the humours of my eye is a coloured

medium, probably some modification of blue. I suppose," he adds, "it must be the vitreous humour, otherwise I apprehend it might be discovered by inspection of the eye, which has not been done."

After his decease, these interesting observations, and the point which had been left for inquiry, were not forgotten. In obedience to the directions of Dalton, an examination of his eyes was made by Mr. Ransome, and his colleague Mr. Wilson, of the Manchester Infirmary, and with the following account of which Mr. Ransome has very obligingly furnished me.

"On the cornea appeared the usual areus senilis, but its centre was perfectly transparent, and free from any tinge of colour. The aqueous humour, received from a puncture of the cornea into a watch-glass, was viewed by reflected and transmitted light, and found to be perfectly pellucid and free from colour. The vitreous humour, with its hyaloid membrane, was also perfectly colourless. The crystalline lens was amber-coloured, as usual in old persons. A vertical section at right angles to the axis was made in the other eye, without disturbing the position of the crystalline, &c., and through this portion of the eye, laid horizontally, some of the colours were examined which Dalton had been unable to distinguish, particularly red and green, with, Mr. Ransome states, no appreciable difference to his vision. These results were transmitted to Sir David Brewster, who visited Mr. Ransome for the purpose of examining the eyes, and they agreed that the imperfection arose from some deficient sensorial power rather than from any peculiarity in the eye itself.

I read, and I am sure the Fellows of the Society will hear, with pleasure, the conclusion of the communication which Mr. Ransome has been so kind as to favour me.

"As a man, a member of society, apart from his position as a philosopher, the character of Dalton was almost perfect. Simple, warm-hearted, unassuming, temperate, and truthful, he could unbend from his scientific contemplations, and accommodate himself to the circumstances of the moment, particularly in the social circles of his intimate friends, when it could be discovered that the grave philosopher had a fund of sly humour, and aptitude for enjoyment quite unexpected. Though he never sought distinction, and passed two-thirds of his life without due appreciation of the value of his labours, he was not indifferent to the honours which, in his later years, were heaped upon him. His face beamed with modest pleasure when, at the Manchester meeting of the British Association, he received the homage of the assembled philosophers."

Mr. Ransome further informs us that "Manchester never presented such a scene

as on the day of his interment; there was a general suspension of business, and the assembled thousands behaved with the utmost decorum as the long cavalcade passed through them to accompany his remains to their last resting-place. Many, probably a large majority, could not understand the meaning of the ceremony, but they knew it was in honour of a great and good man, and one of humble birth."

So completely have the public journals anticipated me in the details of the professional career of Sir Henry Hallford, that the repetition of these would be a needless occupation of your time. Sufficient, therefore, it will be for me to touch on those constituents of his character which so wonderfully won for him the patronage and confidence of the aristocracy, not of birth alone, but of the higher order, the aristocracy of intellect; for, be it remembered, that Hallford, the confidential medical adviser of three English Sovereigns, was also the physician, and the literary correspondent, of a large proportion of the most distinguished men of his time. It is well known that he established the evening meetings at the College of Physicians, and mainly supported them for several years by the productions of his pen, afterwards published as essays and orations; it is also known that he twice delivered the Harveian Oration, and that in the year preceding his death, he presided in this room at a meeting of the profession, convened for the object of establishing the Sydenham Society. These are so many proofs of Hallford's professional zeal, that, when viewed in conjunction with the ability he displayed in every thing he undertook, they afford some help to an explanation of the reputation he enjoyed. It has been stated that Hallford as much surpassed his eminent cotemporary, Baillie, in the power of promptly ministering to the relief of symptoms, as did Baillie surpass him in anatomical and pathological knowledge, the only sure ground of diagnosis in disease; and, yet, if Hallford was thus remarkably apt in the suggestion of remedies, this must have been no unimportant element in his success. Hallford, at the commencement of his career in London, was appointed physician to the Middlesex Hospital, but within the short period of seven years, he rose so rapidly into practice that to remain in this office was no longer an object of his desire; he resigned it, and, from this time, was so thoroughly engrossed by the engagements of private practice and general society, in which he largely mixed, that he indeed "had no unwelcome leisure to employ in writing books on physic." The fulness and the overflowings of his mind were almost wholly upon his favourite classical and literary subjects; we must not therefore be surprised to find that, as a

trustee to Rugby School, and greatly to his credit, he actively promoted the election of Arnold to the head-mastership, as we are told in the life and correspondence of that eminent individual. If Halford had, as Heberden, and other distinguished physicians, have done, recorded more of observation and commentary on the treatment of disease, his claims upon our gratitude would have been greater; but still he was a benefactor to his profession, contributing largely as he did, by his association with the great and the learned of his time, to maintain for the medical profession that station in general society which does not, in the same degree, belong to it in any other country as it does in our own.

Dr. Barlow was a distinguished physician at Bath, for nearly forty years. One who states, and I believe with truth, that he was long and intimately acquainted with Dr. Barlow, has recorded of him that "he cultivated medical science with zeal and assiduity; that his exertions were not limited to objects connected with his profession; that he was the zealous and eloquent advocate of every project that was calculated to extend knowledge, promote humanity, or in any way to be useful to his fellow-creatures; that his benevolent feelings led him to support with his pen, his purse, and his personal exertions, every object of public charity and utility." Such an amount of worth in a departed Associate deserves honourable mention from the chair of this Society.

Dr. Thomas Hope commenced his public career as the Professor of Chemistry in the University of Glasgow, then he became Professor of Medicine in the same University, and was afterwards transferred to the chair of chemistry in the University of Edinburgh, which he occupied for nearly half a century. He enjoyed the highest reputation as a lecturer; his theatre was for many years crowded with pupils attracted by the eloquence of his discourses, by the completeness with which he taught the science of chemistry, but especially by the remarkable neatness and success of his experimental illustrations; but it does not appear that he made any discoveries in his favourite science. His only publication I believe to have been, "An Account of a Mineral from Strontian, and of a peculiar species of earth which it contains," read before the Royal Society, in the year 1793, and recorded in their Transactions.

Dr. James Home occupied a Professorship in the University of Edinburgh upwards of forty years, first in the Chair of Materia Medica, then, from the decease of Dr. Gregory in 1821, in the Chair of the Practice of Medicine.

I have not discovered the record of any observations by Dr. Home on the sciences

which he was for so long a period engaged in teaching, yet the notice of him by his contemporaries is in the highest degree respectful, for it is said of him that he was a most zealous teacher, that no Professor in the University took more pains in the preparation of his lectures, and it is added, that in private life he was held in much esteem.

With Mr. Tupper I had not the pleasure of a personal acquaintance, but I know that he was much respected for the soundness of his practical knowledge, that the uprightness of his conduct, simplicity of his manners, and amiability of his feelings, gained for him the warm attachment of a large circle of friends.

Before I quit this chair, one more pleasing duty remains for me—to acknowledge with unfeigned sincerity the unvaried courteousness and indulgent consideration which I have received from the Fellows of the Society through the period of my Presidency; to acknowledge besides, the kind and willing assistance rendered to me in the discharge of its duties by the members of the Council, and especially by my friends, the Secretaries. In perfect truth, I can state that the recollection of the occupancy of the Chair of the President of the Royal Medical and Chirurgical Society will ever be associated in my mind with the feeling, that, whilst it has been the most dignified period, it has been, at the same time, one of the happiest portions of my professional life. My gratitude for the honour and the kindness which I have here received, will, I trust, be manifested by cordially uniting with you, gentlemen, in the support of our Society, which I firmly believe to be inseparably associated with the respectability and the scientific character of our profession.

EARLY APPLICATION OF THE CHILD TO THE BREAST.

To the Editor of the Medical Gazette.

SIR,

IN your number for 28th February last, I find the following extract from a recently published work of Dr. Marshall Hall, on the propriety of an early application of the child to the breast:—

"I do not pretend, in the above proposition, to have advanced anything new; but, in proposing such promptitude, perseverance, steadiness, and decision of purpose, with which I recommend the measure to be adopted, if these be fully apprehended, I BELIEVE I DO PROPOSE SOMETHING NEW."

Permit me to say, that these observations are not entirely new; in proof of which, I

beg to refer to a short paper of mine in the *Lancet*, of 18th May last, where I recommend the child to be applied to the breast immediately after it is dressed, and in much stronger language and more fully than is done by the Dr. in his observations on this branch of his subject.—I am, sir,

Your obedient servant,

JOHN PATERSON, M.R.C.S.L.

Aberdeen Place, St. Nicholas St.,
15th March, 1845.

ASSOCIATION OF GENERAL PRACTITIONERS.

To the Editor of the Medical Gazette.

SIR,

IN your comments upon the Association of General Practitioners recently formed, and in the arguments adduced by you against it, there is one which has hitherto been put forward less forcibly and prominently than its importance deserves; and it is one which I think would have great weight with many of the members of that Association, if it were more seriously dwelt upon. Of the large number of the medical practitioners who have joined it, probably by far the majority are members of the Royal College of Surgeons of London; and it is to these alone that my remarks can apply. At the time of our admission as members of the College, we all take one oath, "to observe the by-laws; to obey every lawful summons issued by order of the Council, having no reasonable excuse to the contrary; and to the utmost of our power to maintain the dignity and welfare of the College." Now, there can be no question that the chief portion of those who have enrolled their names in the new Association have entirely forgotten having taken such an oath, or, if they remember having taken an oath at all, they have forgotten its nature and contents. In fact, it is generally considered so much a matter of mere form, that members on their admission take the oath, receive the diploma, pay twenty guineas to the College, and, perhaps, give something to the porter, without thinking that one of these acts is of any more importance than another. But, whether we think of it or not, we are certainly bound by that most solemn engagement not to do anything which is prejudicial to the College, as long as we remain members; and, if we should, through forgetfulness, or, intentionally, do any thing injurious to it, we are unquestionably breaking our oath, whatever degree of moral blame we may, in our own minds, attach to so doing. It is probable that the recent acts of the Council have been the cause of so large a number of members having joined the Association; as they have thought, and with justice, that those acts

have been regardless of the wishes, and injurious to the interests, of the members generally. But it must be observed, that we are not bound by any engagement to the Council; it is to the College that we have sworn attachment: and the College, certainly, consist of the whole body of the members, the Council being only the executive body for the time being. If, therefore, the members think themselves injured by the Council, they are perfectly at liberty to use any means within their power to alter its constitution, or to induce a different course of conduct; and this they may do by memorializing Her Majesty's Secretary of State, Sir James Graham, to include the College in his bill for granting new charters to certain Colleges of Physicians and Surgeons, and to make due provision in any new charter for the proper recognition of the rights and wishes of the members generally. Many of those who have joined the Association have done so merely with a view of frightening the Council into a different course of action; and, if this object were effected, they would have no wish to become members of a new corporation, but would withdraw their names, thinking that all had been accomplished which they desired. Now, Sir James Graham has expressed himself very strongly against doing anything which should be injurious to the College: although he has given a favourable answer to the representation from the new Association, there can be little doubt that if he saw sufficient grounds for obtaining a charter from Her Majesty to form a new body, he would consider them more than sufficient for desiring one which should have the effect of merely changing in some respects that body in favour of which he feels so strongly. If the charter for the General Practitioners should be obtained, it will have the effect of seriously injuring the College, by causing many, if not most of those who would hereafter have become members of the College, to become members of the new body; at least, this is the expectation of those who have acted in the matter. Now, whether the charter is obtained or not, or whether, if obtained, it would have the above effect or not, has no effect upon the present consideration. All those who have joined the Association, have, in a moral point of view, injured the College already, just as much as if the above effect had actually been produced: for they have done so as far as their actions are able to accomplish it: and whether the anticipated consequences of those actions do or do not follow, they are morally responsible for whatever may happen. There is, however, one way, and only one, by which they can escape the violation of their oath, if they continue their names upon the roll of the new Association, and that is, by resigning their membership in the

College. As soon as they do this they are relieved from all engagements into which they entered, and which are expressed in the oath as being binding only "whilst a member of the Royal College;" and, in the bye-laws of the College, there is a provision, by which a surgeon may resign his membership. But here we are met by the difficulty, that, on doing so, he must pay a fee of ten guineas, besides the stamps, &c. Now the only answer to this is, that we all knew, or might have known, of this law, before becoming members, and, therefore, in doing this, we acted with the knowledge of the consequences which it involved. It appears, then, that the members of the College, who are also members of the Association of General Practitioners, are placed in the unfortunate position, that they are morally breaking their engagement to maintain the welfare of the College, and that there is no way in which they can escape from this difficulty but by ceasing to be members of one or the other; and whatever may be our grounds of complaint against the Council, these do not relieve us from our obligations to the College; nor can anything but a formal resignation, according to the bye-laws, to which we are all sworn, release us from these obligations. The question is one of far higher importance, than merely whether a man shall sign himself M.R.C.S. or M.A.G.P. It is a question which involves the consideration of the nature and obligations of an oath, and one which imperatively demands a more thoughtful and practical consideration than has in many instances been bestowed upon it.—I am, sir,

Your obedient servant,

M.R.C.S.

Liverpool, March 15, 1845.

REGISTRATION UNDER SIR JAMES GRAHAM'S NEW MEDICAL BILL.

To the Editor of the Medical Gazette.

SIR,

MAY I hope that you will give early publicity, in the pages of your journal, to the following letter, which I addressed to Sir James Graham, on the above subject, and also to the answer which I received to it.

I am, sir,

Your obedient servant,

CHARLES CRADDOCK.

March 18, 1845.

*To the Right Hon. Sir James Graham,
Bart. Secretary of State for the Home
Department.*

SIR,—As considerable doubt exists in the minds of medical men as to the interpretation of clauses 13 and 32 of the "Bill for

Regulating the Practice of Physic and Surgery," I should esteem it a favour if you would oblige me with answers to the following questions:—

1st, Would Members of the College of Surgeons, who hold also the license of the Apothecaries' Company, be allowed to register as Surgeons and also as Licentiates in Medicine; and if so, would the double fee be required for such registration?

2dly, Would individuals who hold the diploma of the College of Surgeons only, and who have passed no examination whatever in medicine, be entitled to register as Licentiates in Medicine and Surgery, and to recover for attendance on medical as well as on surgical cases; and, on the other hand, would individuals who hold only the license from the Apothecaries' Society (and there are very many such practising as general practitioners) be entitled to register as Licentiates in Medicine and Surgery, and to recover for attendance on surgical as well as medical cases?

As meetings of the profession are about to take place, I think it very desirable that your opinion on these points should be ascertained.

I have the honour to remain, sir,

Your obedient humble servant,

CHARLES CRADDOCK.

March 10, 1845.

Whitehall, March 17, 1845.

SIR,—I am directed by Secretary Sir James Graham to acknowledge the receipt of your letter of the 10th inst., upon the subject of the Medical Practice Regulation Bill, and to acquaint you, in answer to the first query in your letter, that the bill does not contemplate double registration, nor would anything be gained by it.

Members of the College of Surgeons will be entitled to register as surgeons, and being so registered, may practise as general practitioners if they please.

With respect to your second query,—It is believed the number of those who have passed the Surgeons' College only, and yet practise generally, is not very great. They will be entitled to register as surgeons, and to practise generally under the Bill.

Those who have the Apothecaries' license only, will be entitled to register as licentiates, and to practise generally in surgery as well as medicine.

There is some inconvenience in this course, but not so great as would follow the opposite course.

Hereafter the Bill makes provision for complete examination in both medicine and surgery.—I am, sir,

Your obedient servant,

S. M. PHILLIPS.

To Charles Craddock, Esq.

6, Chapel Place, Cavendish Square.

TWO CASES OF LUXATION OF THE ILIAC BONE UPON THE SACRUM.

THE editor of *L'Expérience* records, in the number of that journal for 28th September, 1843, two cases of this very rare form of luxation, for which he is indebted to MM. Tavignot and Peste, internes in the service of M. Lenoir, at the hospital Necker. He prefaces them with the remark, that, in the opinion of Boyer, "instances of simple luxation of the bones of the pelvis, from external causes, are so extraordinary that it would be very difficult to believe in them, had they not been observed by men whose honesty and exactness were well known." Both of these cases presented themselves in the hospital at the same time, although one of them is not, strictly speaking, an example of simple luxation, the luxation of the iliac bone being evidently complicated with fracture of the ischium and pubes.

CASE I., reported by M. Tavignot.—On the 1st of August, a man named Bonhomme, aged 32, a blacksmith by trade, entered the surgical wards of M. Lenoir. He stated, that on the evening previous to his admission, having just entered his house, he went towards a window without any guards, tripped, and fell from the third story to the pavement below. He could give no account of the manner in which he fell, having lost his consciousness until the following morning. His condition, when examined upon entry, was as follows. A vast extravasation of blood occupied the whole upper part of the right thigh, and appeared to extend to the corresponding abdominal parietes. He could not move the lower extremity, which was, at first sight, shorter than that of the opposite side; the point of the foot was turned slightly outwards. His urine was passed with difficulty, and was drawn off for two days. He was bled twice, twenty leeches were applied to the thigh, and he was laid upon his back. No accident occurred; the tumefaction, extravasation of blood, and pain, disappeared, so that the patient, who, at the beginning, could, but with very great difficulty, move himself in his bed, got up on the 15th September, and was even able to walk a little with crutches. What was his affection? The following statement will show. The length of the limbs, measured from the spine of the ilium to the external malleolus, on both sides, is exactly the same, and yet the right limb looked shorter than the left, at least two centimeters. The foot is not turned either inwards or outwards. The right anterior superior spine of the ilium corresponds with a horizontal line drawn through the umbilicus, while the left is situated five centimeters below it.

The fold of the right groin is somewhat higher than that of the left. Upon feeling carefully and comparatively the horizontal portion of the two pubes, it is easily perceived that on the right side, and starting from the symphysis pubis, the os pubis is somewhat higher than on the opposite side; at the same time, a hard resisting body, with an uniform surface, which appears to be situated in the iliac fossa, may be felt from the iliac spine to the spine of the pubes. This surface is nothing else, as is evident, than the horizontal portion of the pubes, which has been elevated about three or four centimeters. Examination per rectum enables us to ascertain that the tuberosity of the right ischium is sensibly nearer the median line, at the same time that it is elevated. The right branch of the pubes appears, also, to have mounted at the symphysis upon that of the opposite side, so that it is, in respect to the finger, upon a plane anterior to that of the left side. Behind, we remark that the fold of the buttock is situated four or five centimeters above that of the opposite side; the tuberosity of the right ischium has mounted at least four or five centimeters upon the median line; the sacrum has its normal configuration, but upon its right edge a very sensible depression is observed at the level of its junction with the ilium; the right buttock, instead of the prominence presented by that of the opposite side, offers a very marked depression. Pressure on this spot is very painful, though there is but slight oedema. The two iliac crests are far from being on the same level. A horizontal line passing from the right one passes five centimeters above the left. It should be noticed that the posterior spine of the ilium, and particularly the crest of the right side, are, as it were, thrown backwards, that is to say, they are situated upon a plane posterior to that of the same parts on the opposite side. The vertebral column appears untouched. There are, at present, no longer any traces of sanguineous extravasation, and every thing leads to the hope that gradually the motions necessary for progression will be re-established, if not entirely, in consequence of the inevitable limping which will remain, at least in a manner sufficient to allow the patient to return to his ordinary occupations.

CASE II. reported by M. Peste.—Chavanne, a ragman, aged 39, was brought to the Necker Hospital on the 28th July, having just fallen from the top of a staircase. He had spit blood; several fractures of the ribs were ascertained, both bones of the forearm were broken, and, besides, a severe contusion of the right hip was observed. The pain was excessive, the swelling considerable, the sanguine effusion very great; no movement of the patient could be made

without causing him to utter loud cries, and to resist any effort at examination. A slight apparent shortening of the limb gave rise, at first, to a fear of fracture of the neck of the femur. M. P. seized the leg, and raising it, easily moved the limb, although the patient, suffering severely, contracted quite violently his muscles; the great trochanter followed all the movements of rotation of the femur; no sign of crepitus, no deviation outwards was observed. The absence of these signs caused M. P. to abandon his first idea, and to believe he had to do with a contusion of the hip, complicated with a great extravasation of blood.

Next day, M. Lenoir observed again all these lesions; but the swelling and pain prevented a thorough examination of the state of the hip. The patient had, besides, expectorated pus, and suffered extreme difficulty of respiration, to which symptoms attention was chiefly directed. Under the influence of bleedings, the expectoration of pus ceased; the fractures were united; the swelling of the hip, with the effusion of the blood, disappeared; but the pain continued, and movements were impossible. A new examination at this time resulted as follows:—

The patient was placed upon his back; there was then felt, at the level of the spine of the right pubes, a pretty deep depression, above which, on depressing the abdominal parietes, a pointed, moveable, bony tumor, could be felt, which appeared to be formed by the horizontal branch of the pubes, which was fractured and elevated: the anterior superior iliac spine was carried more backward and higher than that of the opposite side. A sound passed, without obstacle, through the urethra into the bladder, and the patient experienced no retention of urine. By examination per rectum, behind and on the right side, irregularities could be observed, which could only arise from fracture of the ischium; above, and also on the right side, by strongly depressing the anterior portion of the rectum, another tumor could be felt, which appeared to be occasioned by a fracture of the pubes: nothing similar on the opposite side. The patient had remained, from the day of his fall, eleven days, without a stool.

Upon placing the patient upon his belly, the right buttock was observed to be flattened, soft, depressed; the fold of the buttock had risen about two centimetres, and described a straight line, directed obliquely from above downwards, and from without inwards; that of the left side was horizontal, and described a curved line, with its concavity upwards. The posterior superior iliac spine was about three centimetres higher than that of the opposite side, as were also the crests of the ilium and the ischium.

Upon pressing at the level of the left iliac spine, the prominence it forms, and, lower down, the projection of the sacro-spinal ligament, were observable; while, at the same points, on the opposite side, a pretty deep impression was found, in consequence of the elevation of the iliac spine, and the rupture of the right sacro-spinal ligament.

An examination of the inferior extremities showed that that of the right side was shortened, the right malleolus externus being about three centimetres more elevated than the left; but if the measure was taken from the anterior superior iliac spine to the respective external malleoli, the distance was equal on both sides, as it ought to be, since the relations of the coxal bones had changed with the vertebral column alone. All these signs became more evident on placing the patient upon his knees, while bending his body forward.

He was kept in an immoveable position. Several days previous to the 15th September, the day on which the case was reported, he had begun to walk with crutches; he bears upon the leg, but gently, it being as yet unable to sustain the weight of the body; he limps, throwing his body strongly over to the sound side; all pain has disappeared. This patient will be cured with a shortening of the right leg. Here, as is evident, the luxation is not simple, being complicated with fractures of the pubes and ischium, which must necessarily occur to enable the coxal bone to experience a general movement upwards, unless separation of the symphysis pubis had occurred. When this separation exists, the symptom noted by Hippocrates, retention of urine, is observed; in this case it was absent, and, indeed, the fracture had left untouched the ligaments which go to the bladder, but there was retention of faecal matter, which should, perhaps, be attributed to the fracture.

The editor of *L'Expérience* observes, in a note, that these luxations occurred in consequence of very great violence, not in scrofulous patients, easily affected by such a cause, but in strong healthy men, in whom there was no reason to suppose a previous relaxation of the ligaments of the pelvis. The diagnosis of the luxation presented no obscurity, being easily deduced from the elevation of the iliac crest and of the fold of the buttock, the depression of that part, the general shortening of the limb, without alteration of the relations, or of the length, of any of its parts, &c. The prognosis of this affection has been considered as very grave by authors, Boyer remarking that, without considering the immediate effects of the external violence, it is constantly followed by an inflammation, of which the consequences may be very serious, as well on account of the extent of the articular surfaces affected,

as because it may extend to the peritoneum and the viscera of the pelvis and lower part of the abdomen, or may terminate by a supuration of the articular surfaces, or of the cellular tissue of the pelvis. None of these consequences were, in these cases, observed, and were indicated by him probably rather *à priori*, than from the observation of cases. This surgeon himself cites a case which resembles entirely, in this respect, those which precede.

"The most interesting case known," says he, "of luxation of the hip bones, exempt from these formidable consequences, was observed by Enaux, Hoin, and our colleague, Professor Chaussier, and inserted in the collection of the Memoirs of the Academy of Sciences of Dijon. The left os innominatum had been displaced and carried upwards. The inflammatory condition did not allow reduction to be made. After some days, during which relaxing applications and an antiphlogistic regimen were adopted, the replacing of the bones was attempted, but prevented by the return of the pains and inflammatory symptoms. Some days later a new and still ineffectual attempt was made, and was then entirely abandoned. Finally, after prolonged repose, but less so than could have been desired, the patient quitted his bed; and having begun to walk, aided by crutches, the weight of his limb brought about part of the reduction, which had previously been vainly attempted. The cure was perfected, and the patient was able to resume his occupation of tiler. This fact proves conclusively," adds Boyer, "that, in cases of this nature, the most important consideration should not be to seek to cause the reduction, but to combat, by every possible means, the inflammation and its consequences. Too fortunate to obtain the cure at the expense of whatever possible deformity."

M. Lenoir followed the advice of Boyer; he abstained from any effort at reduction, and, besides, how could you reduce, or, at any rate, how could you maintain, in a state of reduction, a luxation of this kind?*

LECTURES ON THE NATURE AND TREATMENT OF DEFORMITIES,

*Delivered at the Royal Orthopædic Hospital,
Bloomsbury Square,*

By R. W. TAMPLIN, F.R.C.S.E.

Surgeon to the Institution.

Rachitis: True—Congenital—Non-congenital—False—Non-congenital—Treatment.

I SHALL now, gentlemen, proceed to the consideration of rachitic curvatures of the bones, of which so large a proportion of cases present themselves at this charity. By the term Rachitis is understood a softened condition of the bones of the extremities, or of the bones generally; and almost all the authors who have written on this subject include under this head curvature of the bones, whether arising from disease which affects the general health and constitution of the patient, whereby the bones are not only softened, but also altered in size and form, the disease influencing the growth and development of the bones, and those cases, of which so many are to be seen, of simple curvature of one or more of the bones of the lower extremities, which exists without any other alteration in their relative or normal proportion; the one being totally different in cause and effect from the other. I would therefore confine the term rachitis to that condition in which there is evidence of disease affecting the bones and body generally; and *false* or *spurious* rachitis, to that condition in which a simple curvature exists without any other change or alteration.

By "rachitis," then, you will understand that diseased and softened condition of the osseous system generally, which has for its results not only a curvature of one or more bones, but an actual change in their relative

proportions; this change being a diminution in length, with an hypertrophy in size. It is both congenital and non-congenital. Cases are mentioned by Hippocrates of congenital rachitis, and also by others, so that it has been known and recognised from the earliest history of surgery. I have been fortunate enough to meet with a specimen in a seven months' fetus, of which this is the skeleton; and you will observe that the long bones of both the upper and lower extremities are about twice their natural thickness, and about a third, or perhaps more nearly one-half, shorter than natural; that the tibia and fibula of both legs are curved severely, the fibula outwards, the tibia inwards; that the radius and ulna of both upper extremities are also curved outwards and inwards; that the ilii and scapulae are enormously hypertrophied, and the head, as is usual, very nearly twice the natural size; the parietal suture ankylosed at its middle third, and talipes varus of both feet (vide fig. 1.) The extremities of all the long bones greatly enlarged, having more the appearance presented in the skeleton of the elephant. There does not appear to be a deficiency of earthy matter, but there evidently is a want of cohesion between the earthy particles, as if the cellular tissue itself did not possess the power of retaining in apposition, that is, the natural close apposition which is common to the healthy bone. In this instance the parietal bones, as stated, were partly ankylosed. In this subject tubercular matter was freely deposited in the liver and other organs, and also on the inner side of the sternum, as may be here seen. [The preparation was here shewn, together with the liver.] I have not been able to trace the history of the parents, which renders it somewhat incomplete, although no doubt exists in my mind of its being hereditary.

In this affection, then, you will have, combined with curvature of the bones, a generally diminished stature, and very frequently the evidence of tubercular disease,

FIG. 1.

Illustration of congenital rickets, combined with talipes varus of both feet.

with which it appears to be, as far as my observation goes, almost invariably connected; for in those instances that have presented themselves at this Charity, that peculiar diathesis common to tubercular disease has been most apparent. In this case, taken from a patient 18 years of age [exhibiting it], who was afflicted with severe knock-knees, with curvature of the bones of both the upper and lower extremities, and flattening of the ribs, the only organ that appeared at all approaching the natural size, was the organ of generation, which appears in these cases to retain its full vigour; for I believe that consumptive patients are not deficient in the power of reproduction. In these cases the softened condition of the

bones is confined to children under 5 years of age, for after that period, although the bones never possess their normal proportions, yet they become as hard as the healthy bone, and in some instances are stated to be actually stronger; as, if the curvature is not removed in childhood, a deposit of bony matter takes place at the weakest point, namely, the concavity of the curve, which renders them capable of bearing great weight; and if the individual has been subjected to much muscular exertion, and possessed good health, they are enabled to undergo quite as much, occasionally greater, bodily exertion, than an individual who has not thus suffered. This, however, is the exception, for unfortunately many fall vic-

tims to the diseases of childhood and puberty.

In cases which have not been noticed during the first months of existence, but in whom the bones become curved afterwards, you will find the curvature generally forwards, or forwards and outwards, of the tibia and fibula; forwards and inwards, and with which is invariably connected knock-knees more or less severe, with the most

severe form of talipes valgus, arising partly from the curvature of the bones, and also from the general debility from which the patient suffers (vide fig. 2); outwards of the femur; outwards and inwards of the radius and ulna, occasionally so acute, that you will with difficulty reconcile the possibility of its being a simple yielding of the bones, but will at first sight regard it as a badly-united fracture. Flattening of the ribs, with the

FIG. 2.

Diagram taken from the Cast of a child, aged 10 years, in whom every bone appeared more or less curved, with a generally diminished development attributed by its parent to the effects of dentition.

prominent and projecting sternum; occasionally the cartilages of one side of the sternum projecting much beyond that of the opposite side, the patient having what is termed the "pigeon breast." Not unfrequently, also, lateral curvature of the spine, from the same cause, and of which I shall speak when I come to that subject. The

general health impaired, indicated by the pallid aspect, emaciated and flabby condition of the body generally; morbid appetite; irregular bowels; enlarged tumid abdomen, symptomatic of the existence of mesenteric disease,—in fact, a concentration of ills scarcely to be met with in any other disease.

This affection is unquestionably, as I have said, constitutional, but is aggravated, and frequently brought into activity, by dentition; the febrile diseases to which children are subjected, worms, and with bad insufficient diet, deficiency of clothing, &c. &c. They become, in fact, from these causes, as well as from the predisposition to disease, liable from any slight casualty to suffer locally or generally, and are the frequent subjects of strumous disease of the joints, and what is termed "Pott's disease," with angular curvature of the spine.

I regard, then, common curvature of the bones of the lower extremities, without that general rachitic condition of which we have just now spoken, as totally different both in its cause and effects, and have therefore ventured to designate it by the term of spurious or false rachitis, and am of opinion that it may exist without any evidence of ill health, although the irritation consequent on dentition, as well as any of the causes mentioned, which so frequently interfere with the health of a child, certainly predispose them to a softened condition of the bones, but which ceases as soon as the health is restored; and unless the curvature is relieved during the time they are thus preternaturally soft, they become hardened in the curved position, and are rarely remediable.

Muscular action is unquestionably one of the direct causes of curvature, both in this and in the former instance, as the bones are the fulcrum upon which the muscles act; and before, as well as during the action of the muscles, the bones of necessity receive the weight or pressure occasioned by their contractions. In some instances of enormously fat children, the weight of the body appears to be the principal cause, as the upper extremities escape altogether, and the general health of the child does not suffer; and many cases are said by their parents never to have suffered.

The curvature in these cases is generally outwards of the tibia and fibula, commencing just above, or at the epiphyses of the lower extremity of the tibia, and will be found to exist more or less acute, frequently altering the position of the articular surfaces of the head of the fibula, which, carrying with it the condyles of the femur, produces what are termed bow-legs—the legs presenting, from immediately above the ankle-joint, one uniform curve, as I pointed out to you when speaking of the deformities of the knee-joint. It is rare to find the femur curved in these cases; it is most common in true rachitis. You will find also a relaxed condition of the internal lateral ligaments of the ankle, and talipes valgus as a consequence, but more severe in the former instance. The muscles are generally well developed notwithstanding the curvature, which, in the

former instance, is rarely if ever to be met with. In fact, most cases of this kind present a healthy appearance, are of the natural size, and the bones of their proper relative proportions. These latter I regard as "non-congenital," and also, that they are not to be considered as indicative of general or constitutional debility beyond the immediate condition; whereas the former are certainly subjected to general as well as temporary causes. A great deal has been written and said of the enlargement noticed at the extremity of the radius in these cases, some supposing that an actual enlargement has taken place, others that it exists only in the imagination, and that it appears enlarged from the diminished muscular development. In true rachitis there is most certainly an enlarged or hypertrophied condition; in false, I do not believe it exists either in the radius or in any other bone. In the skeleton of the fetus you have had an opportunity of examining, (vide fig. 1) this enlargement of the extremities of the long bones is most evident. The head has been said to be enlarged; the same remarks apply here also, for certainly, in the cases last mentioned, there is no trace of increased size. The pelvis, in true rachitis, does not become developed with the growth of the individual; in false, always in common with the osseous system generally; and I would refer you to a most interesting paper by the late Mr. John Shaw, in the seventeenth volume of the *Medico-Chirurgical Transactions*, in which tables are drawn up, shewing the actual measurement in these cases; so that there are many and most important differences between what I imagine to be two very different conditions, and which will guide you in forming your prognosis, as well as in the treatment, which we come now to consider.

The treatment consists of general and mechanical means. In the severe forms commonly met with of true rachitis, of course your attention must be directed to the general health of the patient; and every means must be used which will have a tendency to alter and improve their condition. The secretions are invariably unhealthy; and the alterative I have found most beneficial has been the Hydrarg. c. Cretâ, in small doses, given regularly every or every other night, not to act as an active aperient, but rather to gently relieve the bowels; and the tonic, the tincture of the sesquichloride of iron, in the form stated when speaking of knock knees. If the bowels are in an irritable state, which is frequently the case in these patients, I have given them with advantage the extract of cinchona, combined with the aromatic confection, and the Hyd. c. Cretâ at night. However, it is immaterial what tonic is used, so long as the object

is gained; and, of course, each individual would adopt that which he believes to be the most beneficial. The diet should consist of a nourishing not stimulating kind. These patients do not bear stimulants, save only in the mildest forms: milk, eggs, meat, bread, and potatoes as a vegetable, I imagine to be the most useful. Unfortunately the great proportion of cases occur amongst the poor, whose means do not, or whose mode of life will not admit of their procuring proper nourishment. Without this, however, it would be useless to treat them, as it is the sheet anchor: change of air and diet is of the utmost importance. The sea side is generally recommended. It is, however, of very little moment, although I prefer the country, where a child can run about without restraint, and without the necessity of being directed in its movements. There is nothing so conducive to health as the free exercise of the limbs of children subject to this disease, in the open air; and there is no place where this can be obtained so well as the country cottage or farm-house. It certainly is of far more importance than all the physic that can be given, and in many instances saves both the life and health of the patient, as well as prevents or puts a stop to the increase of deformity.

As regards the mechanical treatment, your efforts must be directed so to apply your pressure and counter-pressure that the patient shall be in no way inconvenienced; that, at the same time the curvature is being removed, such support shall be given them as will enable them to take exercise with greater facility and comfort than they could otherwise have done, as by so doing a great assistance is given to the improvement of the general health. If, then, the curvature of the tibia is forwards, I would advise your using a straight splint behind the leg, well padded at each extremity, and having a hole cut at the point corresponding with the heel. Let the splint be secured with strapping, or common webbing straps and buckles; and let your pressure be regulated also by means of a webbing strap, first protecting the spine of the tibia with a pad, having a hole cut in it to prevent pressure being made directly upon it. The pressure can be thus increased by the smallest degrees, and with ordinary care will occasion no pain or inconvenience. In curvature of the tibia and knees outwards, adopt the same means, applying the splint on the inside of the leg; and let the strap, with which the pressure is kept up, be applied over the point at which there is the greatest amount of curvature. In cases of curvature of the femur outwards, very little can be done, as there is no means I am acquainted with which will admit of constant and uninterrupted pressure being made. If, as is commonly the case in true

rachitis, you have the femur curved outwards, the tibia outwards, and inward inclination of both knees, I would advise your first removing the deformity of the knee-joints with the straight splint mentioned in the lecture on that subject, and afterwards applying splints on the inside of the tibia.

In all cases that present themselves in the incipient state, when the bones are still soft, by these means the deformity may be quickly and easily removed; but when the bones are becoming consolidated and hardened, the treatment of necessity becomes exceedingly slow, and will require a long and uninterrupted perseverance. The splints must be worn night and day, and removed only once or twice a week, for the purpose of cleanliness. Irons have been used from time immemorial; I object to them because it is impossible to sustain so steady a pressure, or to increase it with the nicety that the common webbing strap enables us to do, without which there is no prospect of removing the deformity. In severe cases of anterior curvature, the section of the tendo Achillis has been recommended. I do not myself see that any advantage is or can be gained by this proceeding, as in no instance can you proceed with rapidity; and before the curvature in the bone can be much relieved, the tendon becomes as strong as ever. It possesses one advantage, and that is, no harm results from such an operation. Some have advised, that before you attempt to straighten the limbs, you should improve the general health; by so doing, however, you must bear in mind, that the bones themselves are becoming hardened, and greater difficulty placed in the way of treatment. I find that the splints, when properly applied, are a direct comfort to the little patients; and the softer the bones are, the greater the facility of removing the curvature, and the less the time occupied in so doing; so that in all cases let this be one of your first considerations. In cases coming under the term "false rachitis," you will rarely find it necessary to interfere with the general health; but, of course, should it be necessary, you will adopt such means as may appear expedient.

We have had but one case of "fragilitas ossium" in the Charity, and this in a female aged 17, who possessed that pallid, strumous, unhealthy aspect, so common in these cases. From her own and mother's account, she had suffered from fracture of the arms, legs, and thighs, about forty times. Walking across the room, the thigh-bone of one or other extremity would suddenly snap, when, in falling, her arm would be extended to protect herself, and the humerus become fractured. There certainly was evidence, from the curvatures existing, of very numerous fractures having occurred. She applied

at the Charity, for the relief of severe anterior curvature of the left tibia, which was bent almost to an acute angle at its lower third, the limb being about four inches shorter than its fellow. The tendo Achillis was divided by my late colleague, and extension kept up with decided benefit, as the leg was lengthened full two inches. Supports from the hip downwards were afterwards ordered, with which she was enabled to walk; and since she left the Charity no return of the fracture has taken place. This condition of bone, as well as the mollities ossium of old people, is totally different from that we have been considering, although some authors have designated the latter by the term of rachitis of old people.

OBSERVATIONS

ON THE

NATURE AND TREATMENT OF THE
MORE IMPORTANT DISEASES
OF THE NERVOUS SYSTEM:

With Illustrative Cases.

By EDWARD BLACKMORE, M.D. Edinb.

Member Extraordinary of the Royal Medical Society of Edinburgh, and Physician to the Bath Penitentiary.

[Continued from page 794.]

CLASS III. ON THE INSANE AFFECTIONS.

In a purely medical view, insanity presents itself under three forms:—1st, that with inflammatory symptoms, as in Cases IV. and VI.: 2d, that in which fever is absent, the pulse firm, not quickened, sometimes slow; the features pallid and shrunk; the blood not inflamed; as in Cases IV. VII. VIII.: 3d, that of sudden and violent paroxysms, with a quick rapid weak pulse, a cold perspiring skin, an extremely pallid wild glistening eye,—the nervous form of mania, of which Cases III. and V. are interesting examples. The diagnosis of this form from the second or the congestive variety of mania, is sometimes, however, extremely difficult, when it occurs in the course of an inflammatory affection of some organ in the chest or abdomen; an attendant hysterical symptom, or restless agitation and tremblings, in some cases help to solve the difficulty; but in others the symptoms are merely delirium, sleeplessness, and incessant talking, with a pulse not rapid or intermittent, but gradually failing in power,—a state not always referrible

to the previous abuse of stimulants, nor to severe depletory measures for the cure of the inflammatory disorder. In some cases digitalis has appeared to me to induce strong nervous delirium; but then the attendant sickness and irregularity of the pulse has clearly indicated the exciting cause. Does colchicum ever induce delirium? The embarrassment of the practitioner can only be relieved by profoundly studying the character of the constitution, and of the diseases to which the patient may have been previously subject.

The second form comprises the most numerous, chronic, and embarrassing cases of insanity. The character of the symptoms is most deceptive; with a low pulse and a cold skin, the most intense sanguineous congestion often subsists in the brain; and the most successful treatment is founded on this view of the pathology of the cases: see Cases I. IV. VIII. In another case of remittent mania, the paroxysm was instantly cut short on making a free incision in the scalp. In this maniacal congestion, however, the contractile power of the vessels is soon exhausted, and nervousness or imbecility is easily induced if depletory measures are carried far. In this order of cases I have known the oxide of zinc and camphor trusted to, when free purging and cupping-glasses on the scalp would have been the best treatment.

In the third form the obvious hysterical state, or the nature of the exciting cause—pain, grief, starvation, evacuations, digitalis, and spirituous liquors—easily suggest the successful use of cordials and opium, as in Cases III. and V. This form sometimes succeeds the first, from the abuse of bloodletting and sedatives.

CASE I.—A female, 33 years old, in the spring of 1831, was affected for two months with habitual pain in the head and vertigo, having been subject to epilepsy for two years previously, from a fright. In May the head complaints were lessened, and she had cough, hæmoptoe, and pain in the side, for three weeks in the second month of pregnancy. The chest complaints were then relieved, and the brain affection returned in severity, amounting to maniacal excitement, with spasms of the eyeballs and alimentary canal; her

manner stupid and silent; the pulse quick, without fever.

Bleeding to twenty ounces.

Then costiveness, which a large dose of calomel and scammony failed to relieve.

A blister, and antimonial mercurial ointment on the scalp; purgative clysters; calomel and croton oil.

In the next eight days a great amendment, from active purging; soundness of mind restored, but severe pain at the top of the head complained of (this might partly arise from the irritant ointment?) Mild aperients were continued, and she regained tolerable health through the autumn; but the epilepsy returned.

I saw her again on January 10th, 1832, when far advanced in pregnancy, in a state of violent mania, after having complained for ten days of pain in the head and sides of the abdomen, and lowness of spirits, with a presentiment that she should not survive her confinement.

Bleeding and purgatives; the blood not inflamed.

The next day an easy parturition, of which she appeared unconscious.

The 13th, in high maniacal excitement.

Leeches and antimonial ointment to the head; purgatives.

The 14th, no lochia, no milk; derangement continuing; pulse low.

A blister on the head; opium with tartarized antimony; a turpentine clyster.

16th, convulsions and death, a fortnight from the last attack of mania.

Inspection.—The scalp very thick; the skull very dense and heavy; the brain indescribably vascular; its blood-vessels amazingly enlarged and turgid; the pia mater extremely vascular; blood effused on it betwixt the convolutions, so as to separate them. The medullary substance dotted with bloody points. A small portion of the surface of the right hemisphere presented the appearance of incipient gangrene; the choroid plexus was studded with albuminous points, and very vascular. The medulla oblongata and spinal chord were much softened. The cerebellum exhibited marks of inflammation and softening, most intense at the posterior part, where fluid blood was effused.

Serum also was effused under the membranes and in the ventricles.

CASE II.—A woman, aged 26, who was subject to "nervous headaches," and had latterly shewn unusual irritability of temper, and mental dejection, was delivered of her first child on June 7th, 1834; and in the night afterwards she was restless, talkative, and did not recognize her nurse; but in the day nothing unusual appeared to her accoucheur, except that she desired improper food, and was impatient of contradiction. On the third day she complained of her head and bowels, and took an aperient, and a narcotic after it; the lochia were then rather scanty, and she was peevish, absent, and indifferent to her infant.

On the ninth day the accoucheur found her raving, but without fever; the pulse low. Leeches and purgatives were used; but the mania continued with little change for the next eight days, and with total sleeplessness. She made little complaint of pain in the head, but it was very hot; costiveness obstinate.

I saw her eighteen days after delivery in high maniacal delirium, without fever; the pulse low, the eye dull, the extremities very cold, sleeplessness and costiveness continuing; yet milk in the breasts. Tartarized antimony was given, and produced vomiting; the strait waistcoat applied; purgative clysters administered; and antimonial ointment rubbed on the head. After this she became calmer, and got some natural sleep; but the insanity continued, she refused all food and medicines, and in a week more died from the exhaustion naturally consequent on violent excitement.

Inspection.—The hind-head large; the scalp thick and vascular; the dura mater, at the vertex, much thickened and opaque; much serum on the arachnoid, which was also thickened and opaque over the hemispheres, dotted with calcareous and albuminous granules; a similar state of it at the base of the brain. The pia mater very turgid with florid blood, particularly betwixt the superior convolutions of the hemispheres, down to their utmost depth, and at the base of the cerebellum. The ventricles contained five ounces of serum; the choroid plexus very turgid. The substance of the whole brain and little brain very soft,

easily lacerated, and dotted with bloody points. The larger arteries much dilated; clotted blood in the sinuses. The upper portion of the spinal chord also very vascular.

CASE III.—A lady of a nervous temperament, and weak habit of body, in September, 1823, when about 38 years of age, was affected with severe gastrodynia, connected with costiveness and mental anxiety, while nursing a sick child; for which tincture of muriate of iron and colocynth were given with little avail. She came under my care on October 1st, 1825, suffering severely from her old malady. A purgative was given, and the stomach was relieved on vomiting. The next day, however, the pain was so severe as to occasion syncope; this was relieved in a few days by camphor and assafoetida, and applying heat to the region of the stomach. The pulse and tongue were then natural. Shortly afterwards there was a return of costiveness, with tenderness of the abdomen, cold perspirations, and pale urine. The antispasmodic medicines were repeated, with ether; and a clyster given, by which scybulous stools were procured, and the pain relieved for a few days.

On the 12th a severe return of pain, with diarrhoea, and extreme collapse of the vital powers; these symptoms abated on taking brandy and purgative clysters, by which again much black fetid stool was discharged. The day following much shivering, occasional vomiting, pulse quick, urine high-coloured

Effervescing salines; mercury with chalk; emollient clysters; and an anodyne cataplasm on the abdomen.

The 14th, pain relieved, but the animal and vital functions very low; the mouth sore from seven grains of the mercury.

Camphor julep, beef-tea, and salines.

The next day an improvement; spontaneous but clay-coloured stools. In the evening extreme exhaustion, and delirium after mental agitation.

Wine, camphor, and tincture of bark given.

The 16th, she had slept and felt revived, but had tremors, and nausea, and uneasiness in the bowels, which were relieved by castor oil, which procured a large solid stool; pulse 110, of good

strength. In the course of this day she was much exhausted, from having had six copious stools; and was revived after taking wine and an opiate.

The 17th, a return of pain at the stomach, and prostration; surfeited by beef-tea.

Camphor, warm friction, and animal jelly, ordered.

The 18th, sleeplessness, throbbing in the head, the bowels having been shut up for thirty-six hours. A clyster, with colocynth in it, then procured a hard stool with relief.

The 19th, some amendment, two dark stools having passed; wine and nutriment relished.

20th, six fæculent stools; the mind hysterical, and the head giddy; a look of dying prostration.

Bitter infusion, with ammonia, given.

The 21st, vital powers improved; the mind anxious; costiveness; acute pain in the epigastrium, followed by a tympanitic state of the abdomen.

The 22d, extreme coldness of the body; tympanitic state better on passing two solid stools and flatus; but restless and incoherent.

Laudanum and fætid spirit of ammonia given.

The 23d, a severe convulsion, and furious delirium; the eyes remarkably glistening, and rolling wildly; the bowels costive; little power of deglutition; pulse extremely weak; mouth aphthous. She appeared dying.

On the next day the same state continued. I gave about 280 drops of laudanum with twelve grains of colocynth, at three doses, in a few hours, with clysters; after which she slept, and on awaking was sane, calm, and happy; the pulse 120.

The 25th, still more improved; pulse 90. Five ounces of natural urine voided, the only dejection for forty hours, half a drachm of colocynth, with two ounces of castor oil, having been given in a clyster without effect. In the evening, however, copious stools and urine were voided.

The 27th, much improvement; natural stools from castor oil. Some fish and wine allowed.

The 28th, a sleepless night, and a return of pain in the stomach. Some castor oil then produced seven fæculent stools, with great relief of all the symptoms.

On the 31st she complained of tremors, and a pricking sensation in the skin, and of the night-mare in her sleep.

Rhubarb, and mercury with chalk; and a meat diet.

November 2d, again unhealthy stools and exhaustion, the medicine being neglected. The alteratives were repeated, with henbane, and aromatic spirit of ammonia, for a few days, with a good effect; when, as she complained of occasional stupor and a throbbing in the head, the stimulant was discontinued, and blue pill alone given.

On the 11th a mucous purging, for which extract of logwood and opium was given with advantage; and the appetite was aided by infusion of hop. A slight diarrhoea, however, continued to the 24th; and about the middle of December, after a return of costiveness, she suffered from dysentery, which was relieved by the warm bath, and opiate-starch clysters; but mucous diarrhoea remained to the end of January, 1826. In the course of the spring her health was restored.

In July, 1832, after fatigue and exposure to cold rain, this patient was affected with pain in the chest, and a catarrhal cough, for which, on the third day of the illness, leeches and sedative diuretics were employed by her medical attendant.

On the 5th day, after a sleepless night, she complained of pain in the head, and manifested confusion of thought, excitement, and alarm of mind, and profuse sweats. The bowels purged. On taking some acetate of morphia she slept calmly. The next day I saw her; the pulse 120, and very low; the countenance haggard; the mind alarmed; the head still pained; a slight cough remaining.

A blister behind the ear; a sinapism to the feet; a spirit lotion on the head; effervescing aperients and alteratives.

The next day I found that she had been in furious mania all the night, and had refused all medicine; the cough gone; pulse 120; no fever.

A drop of croton oil; half a grain of acetate of morphia; and in a few hours a drachm of laudanum in a clyster.

These remedies were followed by copious purging, and calm sleep for twelve hours.

On the 8th day of the illness, and

3d of the mania, still slightly delirious. Two five-grain doses of calomel, and an emollient clyster, the abdomen being tumid; after which a good night and decided relief.

The next day she complained of a sensation of falling on closing the eyes, and of nausea and heat of stomach; the bowels costive; pulse 86, tense.

A poultice on the epigastrium; small doses of digitalis and colchicum.

On the 5th day of the brain affection the mind natural, but vertigo and intolerance of light after disturbed days; the abdomen tender; the bowels costive.

Leeches on the stomach, and a laxative clyster.

After this she had a dysenteric affection, with an aphthous tongue, for a week, which was relieved by laxatives, alteratives, morphia, bitters, and lime water; but it was followed by severe and apparently dangerous diarrhoea for a fortnight, with much emaciation, which was cured at length by opium, catechu, and sulphate of copper; and in the autumn her health was restored by country air.

This lady died in 1837, of apoplexy, from effusion of blood in the brain, and diseased cerebral arteries.

CASE IV.—A man, aged 50, of intemperate habits, was affected in the summer of 1821 with mania, marked by hallucinations of vision and hearing, and incessant loquaciousness in Gaelic, his native tongue, which he had not spoken for some years. The pulse was slow, and there was no fever. The insanity appeared instantly after the sudden recession of erysipelas in the head from a wound. He was bled freely, and the blood was inflamed. After three days the erysipelas returned to the face, and the mania instantly ceased for three days; it then reappeared, with sleeplessness, and severe pain in the head, and high fever. He was again bled largely, and purged (the blood still highly inflamed), and got a drachm of laudanum at nights. Again an interval of sanity recurred, when the face had again become swollen for two days; and this was followed by a third paroxysm of derangement for a week, with lowness of spirits, and dropsical swelling of the feet. By repose, and aperients, and counter-irritants, the disease was cured at the end of six

weeks from the first attack; but he remained feeble in body and mind.

CASE V.—A man, aged 40, of intemperate habits, on August 19th, 1825, was attacked, after a debauch, with pneumonia for five days. He was bled with relief; but on the 15th furious delirium came on, for which he was bled largely twice from the arm, and also from the temporal artery, in the course of thirty-six hours.

On the 17th I saw him in wild delirium, out of bed, struggling violently with his attendant; the pupils dilated and fixed; the skin cool and in profuse perspiration; the pulse 140, and very soft; bowels costive.

Purgatives; a blister on the neck; a poultice on the head; calomel and antimony; and a grain and a half of opium on the bowels acting.

In a few hours he became calm and sensible; the pulse 86; and by the use of salines, and small doses of laudanum, he recovered favourably.

CASE VI.—A youth, aged 15, in the summer of 1823 fell from a hay cart, and struck his head; after which he became insane. Bleeding, and cold washing of the head, was ordered by a physician with success; and in June, 1824, he came under my care for a relapse, in which the perceptions were depraved, the passions excited, the propensities mischievous; the eyes intolerant of light, suffused, and prominent; the head pained and hot; the pulse quick and bounding, but soft; the tongue furred. After being purged, he was bled to sixteen ounces, which induced extreme syncope, the pulse falling from 100 to 60.

The head shaven; a blister on the neck; jalap and calomel as a purgative; and half a grain of tartarized antimony twice a day.

The next day the symptoms were relieved, except that the hallucinations continued; the pulse low.

The medicines continued.

The day following he had good sleep, having been vomited and purged by the medicines.

The 5th day the functions improved, but he fancied himself aboard ship (a sign of vertigo probably). The antimony was continued in frequent doses, after which he was affected with weeping from depressed spirits.

The 6th day the pulse quick; much heat behind the ears; pain and sense of heat in the bowels, and costiveness.

Purgatives, and cold to the head.

The 7th day a more natural state of mind, but febrile symptoms high.

Leeches and purgatives; antimony omitted.

The 8th day, yet more sane; head reported to be well; but pallidness and depression of spirits.

Blue pill with colocynth, and aromatic ammonia.

The next day he had good sleep, and was quite sane.

The 12th day, depressed spirits.

Subnitrate of bismuth, two grains and a half, thrice a day; animal food.

After this his spirits became more depressed, and he was observed to mutter in his sleep; the pulse was 60 in the morning, and 40 in the evening.

In another fortnight a slight return of derangement; and after the cold bath, the pulse fell to 49. The bismuth was omitted, and tepid bathing and purgatives substituted with great advantage. The functions were natural, but the mind depressed on seeing his relatives. Sea bathing was employed beneficially.

In the fourth month, however, he was again affected with violent mental excitement, sleeplessness, and costiveness; the face tumid; the pulse quick; after a bleeding and purgatives he was again relieved; the blood very florid, and the clot soft. In the course of the next two years he got several paroxysms, for which he was placed in an asylum. Afterwards his health was completely restored, and he now fills an important situation with honour.

CASE VII.—A robust man, aged 45, of strongly-marked melancholic temperament, fell into profound melancholy in March, 1825, attended with severe sleeplessness, pain at the epigastrium, flatulency, obstinate costiveness, a milk-white tongue, and a small slow pulse.

Saline purgatives; camphor with assa-fetida.

The medicines being inoperative, croton oil was given, and a blister and antimonial ointment applied on the epigastrium. The costiveness was then overcome, but his despondency remained, and he obstinately confined

himself to bed. Mild cordials and antacids were then used, with purgatives and the vapour bath, until May; at which time the bowels were sometimes costive for four days together, and three minims of croton oil were required to move them; the skin was extremely dry; the pulse 50; the sleeplessness better. A scruple of calomel, with one grain of opium, was then given at a dose, followed by croton oil; and the antimonial ointment rubbed on the head. In July he was well, and resumed his work as a blacksmith.

CASE VIII.—A lady whom I saw a few years ago, in profound and habitual melancholy, with extreme torpor of the nervous functions, which had continued in spite of various remedies, experienced extraordinary relief on accidental uterine hæmorrhage taking place.

SURGICAL CASES

OCCURRING IN THE

ST. MARYLEBONE INFIRMARY,

Treated by

R. A. STAFFORD, ESQ. F.R.C.S. &c.

Surgeon to the Institution.

(For the London Medical Gazette.)

Case of Compound Dislocation of the Ankle-joint.

ANN M'MICHAEL, æt. 55, admitted July 15th, 1844. In going down stairs, she fell, and a compound dislocation of the left ankle was the result. The joint was torn open, the fibula fractured, and the internal lateral ligament was ruptured. She was taken to the St. Marylebone Infirmary, and the dislocation was reduced, and the lacerated parts were kept in apposition by adhesive plaster, bandages, &c. The limb was placed on the side in a semiflexed position, and a splint was applied on the external side of the leg, whereby the joint was steadied by bandages, and kept fixed in one position. Considerable suppuration occurred, which continued for some length of time. The health of the patient declined, and she became much reduced, so much so that it was deemed necessary to advise the amputation of the limb. To this, however, she would not consent; her life was in imminent danger, but nothing could persuade her to have the opera-

tion performed. The limb was dressed with the greatest care, and every means adopted to support the general health. She took bark, quinine, and other tonics, and was allowed porter, wine, strong gravy, eggs, and nutritious diet, as she could take it. She lingered on in a very precarious state for rather more than three months, when a gradual improvement took place. Granulations sprung up from the wound. They increased, and at length covered the opening connected with the joint. The health now improved, and sleep returned, with a good appetite; the wound contracted slowly, and healed, leaving an ankylosed joint. On Feb. 20th, 1845, she was discharged well in health, but having a stiff ankle.

Practical Observations.—This is one of those cases which, although every symptom was against the recovery of the patient, yet from having a good constitution, and being supported, she ultimately struggled through the mischief she sustained from the injury. She was reduced to so low a state that a surgeon was justified in recommending amputation in such a case: indeed, it was his duty to do so, for the chances were so little in her favour that it was a hundred to one if she lived. Such cases are related by Sir Astley Cooper, Mr. Abernethy, and others. Their recommendation was that the limb, under such circumstances, should be removed.

Case of Tetanus, the symptoms of which resembled Hydrophobia.

On Nov. 10th, 1844, Thomas Smith, æt. 14, was admitted into the St. Marylebone Infirmary, with an injury of the great toe of the left foot, which had occurred four days previously, owing to a fall from a horse. There was a deep cut over the first joint, and the part was greatly swollen, and looking red. Leeches and poultices were applied, and the wound appeared to be going on well, when, on the seventh day, he complained of stiffness of the neck, which he ascribed to a cold. On the following morning his mouth became quite close, and trismus was complete, with a bending back of the cervical vertebræ. He could speak distinctly, although his mouth was firmly shut, but he could not swallow, for when an attempt was made, even with a teaspoon, to feed him with milk,

it was convulsively thrown back as in hydrophobia, and he had a dread of fluids, endeavouring by his hands to prevent the nurse from attempting to pour them down his throat, and, if persisted in, it immediately caused convulsions. His pulse was feeble, and at 140, and there was a profuse sweat on the face.

An incision was made into the erysipalatos swelling around the wound, and blood and pus escaped. He was ordered—

Six leeches to be applied as near as possible at the entrance of the medulla spinalis through the foramen magnum into the cavity of the skull. Extract of Belladonna was rubbed along the whole course of the cervical vertebræ, and was frequently repeated. An enema was administered, containing—

℞ Olei Terebinthinæ, ʒss.; Olei Ricini, ʒss.; Decocti Hordei, Oss.; Tinct. Opii, ℥i. M. ft. Enema.

℞ Hydrargyri Chloridi, gr. ij; Pulv. Jalapæ, gr. vj.; M. ft. Pulvis, in melle tertiis horis sumendus. Also—

R Tinct. Canabis Sativæ, ℥xx.; Mist. Camphoræ, ʒj.; M. ft. Haustus, sextis horis sumendus.

When an attempt was made to administer these medicines they were convulsively thrown back.

He gradually got worse, but the convulsions were not severe. There being tenderness, and a disposition to a tympanitic state of the abdomen, he was fomented with a turpentine fomentation. Ordered—

℞ Acid. Hydrocyanici (Scheele) ℥ij.; Morphine Muriat. gr. $\frac{1}{4}$; Mist. Camphoræ, ʒj.; M. ft. haustus, statim sumendus, et repetatur quartis horis.

This draught was convulsively rejected. The breathing now became very difficult, and in twenty hours from the time he was first attacked, he expired.

Post-mortem.—No appearances remarkable in the brain itself, but the base of the cerebellum, the tuber annulare, and the medulla oblongata, were much redder than natural. The medulla spinalis also, along the cervical vertebræ, was redder than it ought to be, but the rest of the spinal chord was healthy; the vessels of the arachnoid membrane of the base of the brain, and medulla oblongata and medulla spinalis in the cervical portion, were injected with blood; there was inflammation of

the mucous membrane of the trachea, the larynx, and of the pharynx.

Practical Observations.—It appears in this case that not only the masseter, and those muscles which shut the mouth, were affected, but those of the œsophagus also, in the same manner as they are in hydrophobia. The moment any fluid was attempted to be swallowed, spasm was induced. It is evident that the Extract of Belladonna had great power in preventing the paroxysms of spasm of the trunk, for hardly any ever occurred. In two other cases of the same description, and where opisthotonos was complete, I have used the Belladonna in the same manner, and in both the exacerbations of convulsion were prevented. The Tinctura Canabis Sativa appears to have been attended with little benefit, but this, perhaps, considering the ejection of everything that was taken, cannot be considered a fair case: as yet, however, the effect of this remedy, from the cases which have been published, appears to be very doubtful.

Two Cases of Phlegmonous Erysipelas, from wounds poisoned by Copper.

CASE I.—Margaret Pitfield, æt. 68, washerwoman, of temperate habits, admitted 13th Dec. 1844, pricked her right thumb with a pin, which ran into the flesh about the eighth of an inch. She afterwards scoured out a dirty copper, and the thumb immediately swelled to double its natural size. On the following day the whole hand and arm became immensely swollen and inflamed. She suffered great pain; fever came on, with a quick pulse, thirst, and a furred tongue. The inflammation rapidly spread in the cellular integument all up the fore arm, and on to the humeral part. Leeches, fomentations, poultices, &c., were applied, but extensive abscesses formed, both in the hand and arm. These were opened, but others appeared in different parts of the cellular integument and under the fascia. Large incisions were made into them, and a profuse discharge of pus was the result. This state of things remained for a considerable time (for at least two months), when the inflammation of the arm gradually abated, and the wounds healed, but the hand, and more particularly the fingers, remained tumid, and more resembled the foot of an elephant, or the disease

termed elephantiasis, than the natural limb. The fingers and back of the hand were œdematous, and it was necessary to make frequent punctures in them to let out the fluid, which was transparent. Abscesses still formed in the palm of the hand and on the wrist, and as often as it was required they were opened. At length it became necessary to make an extensive incision from the middle of the forearm, along the wrist, over the tendons, into the palm of the hand. From this time the swelling went down, and the wound discharged freely. A bandage was lightly applied on the arm and over the hand, so as to make slight pressure. An ointment of the iodide of potash was rubbed upon the tumid parts, and a lotion of the Decoctum Quercu constantly applied. Absorption gradually took place, and the tumefaction diminished. The hand now began to assume its natural form and appearance. The wounds healed, and after four months treatment the patient got well, and ultimately will have a tolerably free use of the hand. The constitutional treatment of the case was, first, during the fever and irritative symptoms, purgatives, sudorifics, and saline medicines. Afterwards, when the active symptoms had abated, and when it was necessary to support the health, bark, quinine, wine porter, and a generous diet.

CASE II.—Hester Jones, æt. 65, charwoman, admitted 21st January, 1845, with abscess in the right hand, and diffuse cellular inflammation, extending a considerable way up the fore arm. Both the hand and arm were immensely swollen and painful. The account she gave of herself, is, that while she was scrubbing the floor, the wires of the brush, which were made of copper, and which, to use her own expression, “were caulked,” ran into the palm of her hand. On the same evening, she found her hand extremely painful, and she could not use it. It began to swell to nearly double its natural size. An abscess formed in the palm, which was opened, and poultices applied. Other swellings formed both on the back and palm of the hand, and which contained pus. These, as fast as they occurred, were opened, but sloughing took place over the tendons of the wrist, which were exposed. This state of parts continued for two

months; at length, the inflammation abated, the wounds healed, and in March she was discharged, cured. The constitutional treatment very much resembled that in the last case. In the febrile symptoms, she took purgatives, antimonials, and salines; and afterwards, bark, quinine, wine, porter, and a nutritious diet.

Practical Observations.—These cases show that wounds can be poisoned by copper, or, rather, its chemical changes. There can be little doubt that what is termed verdigris, or the acetate of copper, having impregnated the wounds of these two individuals, was the cause of the immense irritation and mischief which arose in the cellular integuments and parts around it. In animal poisons, the absorbents take up the virus; they become inflamed in consequence of it, and, through their channels, it spreads on to the glands, causing supuration, &c. Hence we see this occur in dissection wounds, in syphilis, in variola, or small-pox, &c. It appears, however, that when the acetate of copper, or other substances of the same character, poison wounds, they are not taken up by the absorbents, but that their irritating effect spreads on into the net-work of cellular tissue forming the integument, and in so rapid a manner, that tumefaction and inflammation instantly occur. The same may be observed in erysipelas; whatever this poison may be, and a poison it is, for it is infectious from the wound of one patient to that of another, the skin and the cellular structure immediately participate in it; abscesses form, the cellular integument sloughs, and the death of this part, if the inflammation be not arrested, takes place. In the first of these two cases just related, it may be observed the virulence of the poison, and the very great mischief that arose in consequence of it. On the same evening the thumb was double its natural size, and, on the following morning, the hand and arm, extending up to the humeral part, also were swollen to an immense extent. Collections of pus formed in different parts of these swellings, and, as often as they were relieved, others made their appearance, and, after as many as, at least, twenty incisions, and some of them very considerable, the disease abated, and ultimately was cured. In the second case, which was not so severe as the former,

abscesses formed in the same manner, and even sloughing took place over the wrist, exposing the tendons. I am aware that it has been doubted whether wounds can be poisoned by verdigris, or the acetate of copper, and I myself once considered it "a vulgar error;" I have, however, now seen so many cases, and the present two afford such strong evidence of it, that I am disposed to think the fact is established.

[To be continued.]

THE AMENDED MEDICAL BILL.

To the Editor of the Medical Gazette.

SIR,

THERE are probably few members of the medical profession who have not read with pleasure the speech delivered by Sir James Graham in the House of Commons, on the 25th ult., on the occasion of his asking leave to introduce his Medical Bill. The Right Hon. gentleman has evidently bestowed much and careful consideration on the subject of medical reform, and has not been an inattentive observer of what has been passing in the profession during the last six or seven months. There are now surely none who will impugn his motives in bringing forward this measure, or deny that he is actuated by a wish not only to legislate herein for the public welfare, but to make his bill acceptable and satisfactory to the profession itself.

The new bill is in several respects an improvement on the former one. It recognizes to a much greater extent the principle of protection, although the means provided for giving effect to that principle still fall short of what is required, and of what is moreover attainable by act of Parliament. The power to enforce penalties is to remain with the Apothecaries' Company; but it is notorious, that (owing probably to their great expense) the prosecutions hitherto instituted by the Company have been very infrequent; and in the new position it would occupy, if this bill should become law, the penal clauses of the Act of 1815 would be little more than a dead letter. The future licentiates of medicine and surgery would not be licentiates of "the Hall;" and although two persons, appointed by the Court of Assistants, are to aid the College of Physicians in the examination

of this grade, it does not appear that any portion of the examination fee would pass into the coffers of the former institution. Under these circumstances, is it to be supposed that the Apothecaries' Company will undertake to protect the whole of the qualified profession against unqualified competitors? Clause 35 of the present is much more explicit and comprehensive than Clause 31 of the original bill, and under the superintendence of a vigilant Council of Health, might become a very useful provision. The term "doctor," comprises at this time a large proportion of illegal practitioners, but many doctors might hereafter make it appear that they do not profess to be doctors of *medicine* but of *philosophy*, or something else. The author of the bill having acknowledged the propriety of making new restrictions, and of not abolishing others already in force, would it not be better to insert at once a penal clause against—not only those who practise with a fraudulent title—but against those who practise at all—without a license?

In detailing his views with respect to the constitution of the Council of Health, Sir James Graham declares that "general practitioners, and country practitioners, have a right to be represented in the Council;" and he intimates his intention of advising, that a portion of the members of this body, to be nominated by the Crown, should consist of this class of the profession. The Home Secretary would doubtless fulfil his pledge, and there is no reason to fear that he would not make a judicious selection; but Sir James Graham will not be Secretary of State for ever, and there is in the printed bill no provision for the appointment or election of general practitioners, although a clause or clauses to that effect will probably be inserted on the second reading, or "in Committee." It will be observed, moreover, that the physicians and surgeons on the Council would be elected by the fellows of their respective Colleges, while the general practitioners would be appointed by the Crown, the former being elected for three years, the latter (agreeably with Clause 4) holding office during her Majesty's pleasure. Now, whatever regulations are made with respect to one class of the profession, they should apply to all. If the phy-

sicians and surgeons are to be elected, the general practitioners should be elected also. If the latter should be appointed by the Crown, and for life, it cannot be said that their class of the profession would be *represented* in the Council of Health.

Respecting the propriety of all practitioners entering the profession through a common examination and license, the remarks of Sir James Graham are pointed and sensible. "I earnestly desire," says he, "to see one admission to practise, by an examination, common to all; and that after all shall have passed one common portal, each should choose what branch of medicine he may wish to practise." Objections have, it appears, been made, on the part of the College of Physicians, to such an arrangement, on the ground that it would interfere with the courses of study prescribed by the Universities. That the high position in society now occupied by the English physician is, in a great measure, to be attributed to his residence at one of the Universities, and to the connections he is there enabled to form with parties intended for the other learned professions, and with the aristocracy, is undeniable; and it would not be for the advantage of the profession that such a state of things should be annulled; but it is by no means apparent that the views of Sir James Graham, and that large body of the profession who think with him, could not be carried into effect without producing such a result. Were a *minimum* age to be fixed for the attainment of the license to practise, it would not follow that all should apply for it *precisely* at that age. The license would signify that the person holding it was considered a safe and properly qualified practitioner, in the full acceptance of the term. The University degree would denote that he had devoted himself more particularly to the strictly medical part of the profession; and his association with a College of Physicians would show the line of practice he was desirous to adopt. The examination for the license required of him (in common with other grades of the profession) by the State, might be submitted to a year, or a month, or day, within the time of his applying for his degree or admission into a College of Physicians. To insure, as far as possible, both uniformity and efficiency,

Clause 21 provides, that the curricula of study and particulars of examination of the Universities and Examining Boards shall not be valid unless approved by the Council of Health. The doctor of medicine, therefore, after passing the University examination for his degree, as well as the State examination for his license, should be admissible into the Colleges of Physicians without further examination.

The ages at which persons are to be admitted into the different grades of the profession have been frequently commented upon; and it would perhaps be advisable that these should not be specified in the bill, but left to the discretion of the Council of Health. It is considered by many, that, at the age of 21 years, few men are fitted to undertake the responsibilities of the medical practitioner. Sir Benjamin Brodie, Sir James Clark, Mr. Green, and other men of eminence, have expressed an opinion of this kind; and if it be too early now, it will be still more so a few years hence, when, in conformity with the rapid increase of medical science, a greater amount of knowledge will be required of candidates for the license, than they are at present expected to possess.

Clause 20 of the new bill gives to licentiates of medicine and surgery a right of admission (on payment of a fee) into the Colleges of Surgeons, as members or licentiates thereof (the former term would be preferable). They would be examined also by the Colleges of Physicians, and might on that account be associated with those Colleges quite as consistently as with the Colleges of Surgeons. In the profession of the law, we find the same individual admitted as an attorney of one of her Majesty's courts at Westminster, and a solicitor of another. So in medicine, the person intending to practise both medicine and surgery, might be an associate of a College of Physicians, and a member of a College of Surgeons: physicians and surgeons being *fellows* of their respective Colleges. The recent charter of the Col-

* The able Editor of the British and Foreign Medical Review, anticipating the April number of that journal, has put forth a statement relative to the new charter of the College of Physicians, wherein he announces that the fellowship is to be limited to "a small number of the members of the corporation." The fellows at this time are, with few exceptions, physicians residing in London; and as the annual vacancies occasioned by

lege of Surgeons provides that *future* members of the College shall be admitted to examination for the fellowship at the expiration of twelve years from the dates of their diplomas—at the age of 33,—a period somewhat late (a clergyman may be a bishop at 30); but licentiates of medicine and surgery are not to be admitted as associates of the College of Physicians of England until 40 years of age, nineteen years after the period fixed for the license! If, in the first instance, physicians and surgeons are to be admitted at the ages of 26 and 25, and in each case after *five* years of study, surely there can be no good reason for making a difference of seven years in the admission of the associates of one College and the fellows of another. If, as is well known, many of our ablest physicians have been general practitioners, why should the public be deprived of the services of this class in the character of physicians (provided they be men of liberal education, and wish to practise as such), until so advanced a period of life as 40 years. Agreeably with Clauses 16 and 22, the general practitioner, how learned and highly qualified soever he may be, must, in order to become a physician, either matriculate and reside two years in a University for the degree of M.D., and undergo an additional examination before being admitted into a College of Physicians, or he must wait until he reach the age of 40, to be admitted to examination by, and admission into, the College of Physicians of England. Supposing that the Council of Health would insist on licentiates being well educated men, these regulations are more stringent than is necessary, either for the public inter-

ests or for the dignity of the *order* of physicians.

The admission of licentiates to the highest honours and privileges of the aforesaid Colleges at an earlier age than is proposed, added to the provision made by Clause 20, would diminish, in a great measure, the anxiety now felt by a large body of the profession for a College of General Practitioners; as, in this case, a majority of the latter would aspire to become Associates of a College of Physicians, or Fellows of a College of Surgeons. The new College would then consist, *for the most part*, of the junior members of the profession; and it would be better for them even to remain unincorporated, than belong to an establishment which would hold a place in public estimation inferior to that of existing Colleges. In the meantime a more liberal policy should be adopted with respect to the admission of *existing* members into the *fellowship* of the English College of Surgeons: injustice would thus be obviated, discontent removed, and there would then perhaps be no *necessity* to give a vote in the election of the Council to *future* members of the College, as, at a given age, they would all be admissible on examination into the fellowship; and, becoming members with this understanding, they could not complain of any oppressive or invidious exclusion from the privileges of the higher grade.

The advocates for a College of General Practitioners have probably overrated the advantages which such an institution is calculated to afford: in other words, they have looked to incorporation as an instrument for the correction of grievances which are removable by other means. What are the principal grievances which press upon this grade of the profession? The majority of them may be attributed to *unfair competition*, which may be spoken of under two heads—1. Dissimilarity of qualification; 2. Want of adequate protection. Complaints arising under these heads are common to the whole profession—to physicians and surgeons who have their distinct Colleges, as well as to general practitioners who have not. The first of these evils would be obviated by the establishment of that uniformity of qualification, which it would be one of the most conspicuous duties of the

death must be few, and the filling up of the same will be by personal voting at the College, the *fellows* will continue to consist almost exclusively of metropolitan physicians, who will be empowered to elect the governing body, and the representative in the Council of Health of the College of Physicians (no longer of London, but of England. The future "licentiates of medicine and surgery" are to be in part examined by, and of course to pay a fee to, this College, without receiving from it further recognition; and it is to comprise all the physicians in England; but if Dr. Forbes's information be correct, the provincial physicians will have but small *chartered* privileges, besides those of paying their money to the College, and taking in return the empty title of "associate." Let us hope that the learned Editor is under a mistake; but if this be not the case, any such clause in the proposed charter should be vigorously and at once remonstrated against, not by physicians only, but by the whole profession.

Council of Health to procure throughout the United Kingdom (Clause 21). The second would be rectified, as far as it is capable of being, by the adoption of stringent measures against unqualified practitioners. Much discontent has arisen from the over-crowded state of the profession—an evil which has of late begun to correct itself, and which would be still more effectually controlled by such regulations as we are warranted in supposing that the Council of Health would either originate or sanction.

The general interests of the profession would be much more likely to meet with attention from such a body as the Council of Health (fairly constituted), than from the Councils of particular corporations. Our first aim, therefore, in reference to medical government, should be to have the interests and feelings of all classes of the profession adequately represented in this body. Its powers would be extensive in controlling not only individuals but corporations; and the mixed character of its constitution would be a safeguard against unjust or partial legislation. Of its important bearing on the public welfare, nothing need be said in this place.

Without wishing to impute unworthy or selfish designs to the general practitioners of London, than whom a more honourable or useful class of persons does not exist, it is undeniable that many, if not most, of the peculiar benefits to be expected from the establishment of the proposed new College would be confined to their body. The College would have a building, a library, reading rooms, lectures, evening meetings, &c.—all very good things—but which could be very imperfectly shared by practitioners resident in the provinces, and, for those living in London, would be equally attainable through a Metropolitan Association of General Practitioners. As for the examination and licensing of this class of the profession by men of their own grade, there are few general practitioners, I should think, who would not prefer being examined, and having their certificates signed, by eminent physicians and surgeons.

It may be said, that without a distinct incorporation, there would be no satisfactory way of electing persons to represent the general practitioners in

the Council of Health; but this requires confirmation. All members of the Council would, in the first instance, be appointed by the Crown; and when the time should arrive for a portion of them to be chosen by the profession, it would not be difficult to form a constituency out of the registered general practitioners, in accordance with details which should be specified in the bill; and the election of their representatives might be determined by voting papers supplied to those who should demand them, the names of candidates, (previously announced), being given at the same time. If personal voting should be deemed preferable, assessors might be sent to certain places to conduct the election.

The institution of a third College has, I admit, been advocated by a large number of general practitioners, both metropolitan and provincial; the preceding remarks are, therefore, offered with much deference to the opinions of those who are really anxious for its establishment. The arguments hitherto adduced in its behalf, and the proposed methods of organizing it, have failed to convince me, amongst many others, that under existing circumstances and prospects, I should best promote the welfare of the class to which I belong by giving it my support, although not prepared or presumptuous enough to affirm, that under no circumstances, and on no conditions, would an incorporation of this kind be desirable. The solution of this question must greatly depend on the course which matters may take during the next few weeks, and on the position in which the general practitioners are likely to be placed by the proposed bill and College charters*. Sir James Graham has certainly shown no disposition to hurry forward his measures, but has given time for their due consideration and discussion. With respect to his intention of recommending to the Crown the establishment, by charter, of a "Royal College of Medicine, Surgery, and Midwifery," he has declined to pledge himself until further inquiry be made into, and further information be elicited upon, a subject of so much importance. In this he has probably exercised a sound discretion, particularly as three-

* The charter of the College of Surgeons of England, it is said, will be modified, or a supplemental charter will be granted.

fourths or more of the general practitioners of England have, up to this time, made no declaration in its favour. An *Association of General Practitioners* might be very useful both in watching and assisting the Council of Health.

Clause 17, instituting examinations in midwifery, and Clause 36, relating to persons guilty of flagrant misconduct, are useful parts of the amended bill. Clause 31 is a particularly valuable provision. The power thereby given the licentiates of medicine and surgery to demand fees for medical and surgical advice, &c. will be hailed with gratification by those general practitioners who are anxious that their class of the profession should abandon the practice of making their remuneration dependent on the quantity of medicine—not, perhaps, taken by, but sent to, their patients—a custom followed by many honourable and scientific men because it is a custom, although one which is much better calculated to answer the purpose of the knave, or the ignoramus, than of the honest, upright, and intelligent practitioner: the knave, whose conscience allows him to send a larger quantity of medicine than is requisite for the patient's stomach, or the just claims of his own pocket; the ignoramus, who may ring the changes on a variety of "simples" before meeting with one adapted to his patient's case. This has, indeed, been a grievance, and more than a grievance; it has been a degradation to the medical practitioner, and an injury to the public.

The connection of the Council of Health with the Crown has been objected to; on the part of some, perhaps, from want of sufficient reflection on the probable consequences of such an arrangement. We have long complained that medical interests are not understood, and consequently not cared for, by statesmen and legislators, and in what manner could this complaint be remedied so effectually as by connecting the profession with the State, and by having, as the president of its supreme Council, the minister to whom is entrusted the administration of the domestic affairs of the United Kingdom? On the other hand, the State has hitherto but imperfectly availed itself of the services of the profession in the promotion of measures relating to the public health, medical jurispru-

dence and police—in a word, of State medicine. The efforts of medical men have, in times past, been directed chiefly to the relief and cure of diseases; they will henceforth be employed in the not less noble and philanthropic cause of their prevention. To give effect herein to the deliberations of a medical Board, or Council, a connection with the Crown is indispensable. Through the Home Secretary, the Council would be responsible to Parliament; and as the community at large would be deeply interested in its proceedings, it is only right that such responsibility should exist. It hence becomes necessary that the Home Secretary, or some other of Her Majesty's advisers, should have a voice in, or a veto upon, the acts of the Council and the appointment of its members, and this is quite compatible with a full and fair representation, in this body, of the members of the medical profession.

There is now, sir, a reasonable prospect of a medical bill passing the legislature before the close of the present session of Parliament. Its author has evinced a desire to make it a useful and satisfactory bill. The profession will meet his endeavours in a corresponding spirit, and will doubtless, as far as they are able, assist him to render his proposed enactment as perfect as the complicated nature of the questions and interests involved will admit of its being made.—I am, sir,

Your very obedient servant,

CHARLES THOMAS CARTER.

Hadley, Middlesex, March 20, 1845.

MEDICAL GAZETTE.

Friday, March 28, 1845.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

THE ADDRESS OF THE SOCIETY OF APOTHECARIES.

THE Master and Wardens of the Society of Apothecaries have favoured us with their Address to the General Practitioners of England and Wales, on the provisions of the present Bill

as contrasted with those of the one introduced in the last session of Parliament. After careful perusal, we confess our utter inability to discover its precise drift.

The Society set out by congratulating their medical brethren on the fact of their merits having been properly acknowledged by a minister of the crown, and cheerfully accept this as a pledge that in whatever legislation may follow on medical affairs, no measure will receive the support of the Secretary of State, which can be proved to have a tendency to lower the status, or impair the usefulness, of the class of general practitioners. On this point they may rest perfectly secure. We believe it to be the sincere wish of Sir James Graham to promote the good of all parties.

The Society observe that the constitution and power of the Council of Health remain unaltered; still, in consequence of what has fallen from the Right Hon. Baronet, the general practitioners may reasonably anticipate that a portion of the six members reserved to the nomination of the Crown shall be from their body. According to the plan in contemplation, we presume there shall be not less than two general practitioners appointed to the Council of Health, one a town, the other a country practitioner. A college of general practitioners, to be upon an equality with the Colleges of Physicians and Surgeons, would of course be entitled to have only one representative in Council. Thus they would virtually be more fully represented in their present estate, than if embodied by charter.

The Society have no reason to doubt but that the Right Hon. Baronet will state more explicitly whether it is intended that their Court of Examiners shall have an equal voice with the College of Physicians in determining the curriculum of study, and whether,

in conjunction with the College, they shall form a joint board with equal powers as respects all its members in reference to the examination of licentiates.

They are of opinion that the restriction in the Act of 1815, compelling them to elect the Court of Examiners from among the members of their corporate body, is most wisely removed by the present bill. Henceforth the Court of Examiners will be eligible from Apothecaries of ten years standing, (whether members of the Society or not) until there are licentiates of ten years standing on the register, after which the examiners must be chosen from such licentiates.

They observe, that the general practitioners will naturally seek further information touching the provision, that every person registered after examination as a licentiate in medicine and surgery, shall be admitted *as a member or licentiate of the College of Surgeons*. We certainly think this point requires elucidation.

In reference to the midwifery clause, the Society submit to the profession "whether the institution of an authorised although a voluntary examination in midwifery, is not as much as it would be expedient to seek for at the present time." This subject requires mature deliberation, inasmuch as the clause for false pretences of qualification does not hinder any practitioner from calling himself an accoucheur, and perpetrating all species of malpraxis. It is only the other day that a coroner's jury in Norfolk returned a verdict of manslaughter against a member of the Society of Apothecaries, for having caused the death of a parturient woman by forcibly extracting the entire uterus, with several feet of the large intestine.

The clause providing for the registration of medical students is altered,

and in the opinion of the Society improved.

The Society complain that the power of determining *which form of testimonial* (namely, that of physician, surgeon, or licentiate) shall qualify for situations in public institutions, should be vested in the Council. This objection appears to us groundless, provided the general practitioners are to have a voice in that Council, as fully intended by the Home Secretary.

They regret that no attempt has been made in the present bill to diminish the difficulties which beset the enforcement of penalties imposed by the Apothecaries' Act. We know of no means of obviating the difficulties in question, except in making all persons convicted of practising without certificate liable to summary punishment before a magistrate, or two magistrates.

In reference to the new clause, empowering the Council of Health to erase from the register any person who shall be convicted of felony, and so on, they suggest that this would be more likely to answer the purpose, were power given to the said Council to restore a person to the register, whose name had been erased, should a fitting case for the exercise of such power offer. "The inability of the Council, *under any circumstances*, to restore a name which has once been erased from the register, would probably be found to render the Council unwilling to exercise its power in cases which, under other circumstances, would justly merit such a punishment."

The Society conclude by stating, that they shall reserve to themselves the full right of deciding upon the particular mode in which they may be led to further the wishes and objects of their professional brethren.

It would seem from the above document, that the Society of Apothecaries

are ready to do anything, or nothing, just as the tide may turn. The worshipful guild are evidently at a loss which way to steer during these times of agitation and tumult.

GULSTONIAN LECTURES,

Delivered at the Royal College of Physicians,

By G. OWEN REES, M.D. F.R.S.

Assistant-Physician to Guy's Hospital, and Physician to the Pentonville Prison.

IN my last lecture I had the honour to bring before your notice a mode of dividing the blood physically into certain constituents, and entered upon the anatomy of the corpuscle, and an examination of its component parts. I shall now consider the arrangement of these components, as lately described by Mr. Lane and myself, in a paper published in the Guy's Hospital Reports, in which communication we also entered at length on the subject of endosmotic action, as shewn on the corpuscle under the microscope. It will be remembered that the corpuscle has already been described as made up of three constituents, viz. an envelope, a nucleus, and a red colouring matter enclosed by this envelope or sac, and I shall now proceed to describe the manner in which Mr. Lane and myself have been led to believe that those constituents are arranged. The human corpuscle is circular in form, flattened, and has been described to present a double concave surface. Its diameter measures on an average $\frac{1}{2500}$ of an inch. This circular form is given by the envelope, which is distended by contained fluid, and is a delicate membrane, or vesicle, firmly adhering to the surface of the nucleus at its centre. This nucleus is flattened and circular like the envelope, is contained within it, but does not fill it, being only two-thirds its diameter; but it is situated in the centre of the envelope, and is adherent, as before stated, to the membrane at its centre only; leaving a canal all round its free edge, which canal contains the red colouring matter. The nucleus, though flattened and circular, differs from the envelope in not being rounded at its edge. It measures about $\frac{1}{3500}$ of an inch in diameter. Now, though it is not my intention to enter at length on a description of the various methods at present in use among chemists for analysing the blood, I cannot refrain from directing attention to the subject on the present occasion, as there are difficulties in the way of effecting this, which those who have not combined the study of minute anatomy with chemical knowledge can scarcely

have felt, and, until some understanding exists, among those who make anatomy and physiology their pursuit, on several points which at present divide opinions, we can scarcely hope that the application of chemistry to the furtherance of pathological research will be productive of those benefits which so many have hoped to see realized. The attention of chemists has up to the present time been very much directed to the detection of variations produced by disease in the proportions of the three principles or constituents of the blood, viz. the serum, fibrin, and red corpuscles; and a multitude of analyses have been made for the determination of these points in various diseases, and we have as yet adopted no other mode of inquiry (except it be to detail certain abnormal constituents of serum) to discover variations from the established healthy standard. No experiments have been made, for instance, with a view of ascertaining any variations in quality which probably occasionally exist in the normal constituents of blood, the chemical characters of its colouring matter are not well described or understood, and the gases contained are not yet sufficiently examined in health to afford a normal standard of indisputable correctness. The methods at present in use for examining the blood quantitatively will be considered very faulty by all who are well acquainted with even the most obvious physical properties of the blood-corpuscles. The most approved method of chemically ascertaining the proportion of fibrin, serum, and hæmotosine in the blood, is the following; but I must premise that hæmotosine is frequently used to express corpuscles, for it is the weight of these bodies, and not that of the true hæmotosine which chemists obtain by their analyses—a fact showing what disadvantages we labour under, even at the present moment, from a positive want of information on the part of some of those who are employed in chemical analysis. The most approved method of examination is as follows. A portion of freshly drawn blood is poured into a bottle closed by a glass stopper, and containing fragments of lead; this is agitated for several minutes, and weighed, to ascertain the proportion of blood used; the lead is then withdrawn, having collected the fibrin; this is removed, and carefully estimated, after drying and washing, allowance being made for the presence of adherent serum. The fibrin being got rid of, the corpuscles are allowed to subside in the serum, which is then poured off, and means taken to ascertain its constitution. The corpuscles are now dried, having been weighed in the moist state, and the weight when dry subtracted from the weight when moist, which, of course, gives the quantity of water present in the moist mass. This

water being regarded as forming part of the serum adherent to the corpuscles in the moist state enables us to ascertain how much of the solid dry matter is to be considered as solid matter of serum, for having performed the analysis of the serum decanted, of course we have ascertained the relative proportions of water to solid matter contained in it. The quantity of solid matter then indicated by the water evaporated from the moist corpuscles is subtracted from the whole weight of the dry mass of corpuscles and serum, and the difference gives the weight of dry corpuscles. The weight of the solid matter of adhering serum is of course carried to the account of the serum in the analysis.

From what you already know of the physical characters of the blood, you will at once perceive that the corpuscles are estimated here, and not the hæmotosine, as some have presumed; that the blood is divided into serum, fibrin, and corpuscles, and that the weight of the hæmotosine contained within the envelope of the corpuscle is not ascertained. It is important that you should be aware of this, as pathologists, for the red colouring principle has peculiar and important duties to perform in virtue of its chemical characters, which are quite distinct from those of the envelope and nucleus, which are estimated with it in this form of analysis. There is another point to which I must beg your attention, as it shows the absolute necessity of a knowledge of physical structure for those who are occupied in the analysis of the blood. It will be remembered that the first step I described consisted in ridding the blood of fibrin by agitating pieces of lead in a weighed quantity of the fluid, in order that the pieces of metal might collect the fibrin, which could then be removed, washed, and estimated.

From what you already know concerning the physical qualities of the blood-corpuscle, you will at once perceive that from the moment coagulation of fibrin commences, the liquor sanguinis will decrease in specific gravity, owing to deprivation of part of that solid matter which it before held in solution. The necessary result of this must be the establishment of an endosmotic current tending to fill the corpuscle, which will now become rounded and distended. Now since it is probable that in some diseased conditions the specific gravity of the liquor sanguinis may become considerably lowered before the whole of its fibrin deposits from solution, it is to be expected that every corpuscle will be enclosing within its envelope a certain quantity of this principle (fibrin), which will enter it by endosmosis dissolved in the liquor sanguinis, which has become lowered in specific gravity. In this manner we see how it must probably happen, during

this first step of analysis, that a certain portion of the fibrin which, in the natural condition of the blood, existed as a constituent of the liquor sanguinis, will be estimated as hæmotosine, or, rather, have its weight added to that of the corpuscles; the weight of fibrin being proportionally diminished. That the weight thus lost may be very considerable, when the fibrin coagulates slowly and imperfectly, appears pretty certain, for the liquor sanguinis is closely studded with corpuscles, every one of which will take on this action, and enclose a portion of fibrin. If we consider the condition of corpuscles which have endosmosed serum (an action which must always occur) during the coagulation of the blood, we shall perceive that the determination of the proportion of the solid matters of serum has also been interfered with owing to this endosmotic action. According to the view taken by the chemists, we ought to consider the corpuscle of the blood as a solid impermeable body, and the whole of the moisture adherent to it should be water which at one time had formed serum, whereas our knowledge of structure at once enables us to perceive that this proportion of water is in part a constituent of the fluid contents of the corpuscle, which is not serum either in its chemical or mechanical characters, being red in colour, and containing iron, and, moreover, possessing in its natural state a specific gravity exceeding that of the serum; being, indeed, as heavy as the liquor sanguinis. I am anxious that this source of variation in the perfection of chemical analysis as now performed should not be considered as a trivial cause of error, and must therefore again call to mind the enormous multitude of floating corpuscles in the liquor sanguinis, as it exists in the blood, each of which will tend by endosmotic action to vary the correctness of results obtained by chemists, who have conducted inquiries as though these floating bodies were composed of solid tissue.

It appears probable that the analyses of the entire blood which have been made up to the present time, are extremely faulty, and that though they have served to show a difference in the constitution of the fluid in health and in disease, when submitted to the same ordeals of manipulation, still they do not possess that absolute correctness which is desirable, and almost necessary, to enable us to reason correctly on the differences so detected. The point of view in which the examination of the blood should be regarded, in order to render the services of the chemist available to the pathologist, would appear to be that which should embrace the examination of the liquor sanguinis as serum containing fibrin in solution, and, if possible, should treat of the contents of the corpuscles as they exist in the circulation, or as nearly

so as possible: we must always be liable to error if we prosecute analysis, as it is at present performed, by operating on corpuscles changed by endosmotic action in consequence of the removal of the fibrin from the liquor sanguinis. They are no longer in their natural state, but are distended with serum immediately on the blood coagulating, and thus have within them a fluid foreign to their healthy constitution.

The difficulties which I have here shown to exist in obtaining a correct analysis of the blood will serve to impress you with the great importance of an acquaintance with physical structure on the part of those who would apply chemistry to the service of physiology. It is, indeed, not only difficult for one who does not combine these two branches of inquiry to make useful observations in the service of either science as applied to the study of the blood, but it is a matter of impossibility for any one exclusively devoted to either pursuit even to determine the point at which physical methods of examination should terminate, and chemical analysis commence. I cannot do better on this occasion than quote the error already alluded to, which has been made by almost every chemist of the day, in considering the corpuscles of the blood as hæmotosine, whereas they are really organised structures, containing hæmotosine as one of their constituents; for though their weight, correctly ascertained, must bear some comparative relation to the quantity of hæmotosine present, still that which has been presumed by the chemist to be red colouring matter has really in great part been composed of white albuminous matter, viz. envelope and nucleus.

Had the physical structure of the blood been better understood, these errors might have been avoided, and it is to be hoped the time is not far distant when our knowledge will enable us to devise some more perfect method of analysis.

This want of knowledge of physical structure has greatly interfered with our possessing correct information as to the chemical characters of hæmotosine; or the red colouring principle, in its natural state; the processes recommended for its preparation betraying on the part of those who have proposed them a great deficiency in this respect. It is not long since, that, in order to separate hæmotosine, Lecanu recommended that the blood should be mixed with sulphuric acid as a first step in the process; thus embarrassing the result with the products of the action of that acid on the envelope of the corpuscle, which must of necessity be burst or dissolved before the red colouring principle can be attacked; nor can we then obtain what we desire, viz. hæmotosine in solution, free from the action of any

reagent, and in the condition in which it existed in the circulation. Had we attained our present degree of acquaintance with the anatomy of the blood-corpuscle when the examination of the blood was first pursued by chemists, our knowledge of the colouring principle would have been greatly in advance of its present position; and I will proceed to show how we now have the means of examining the soluble coloured contents of the corpuscle freed from extraneous matters, and probably much in the condition in which it existed in the circulation. The success of this method of extraction depends entirely on those physical properties of the corpuscle to which I have called attention.

We first proceed to obtain the corpuscles in a pure state, and washed clean from the solution of animal matters in which they float. You now know that this can be effected by pouring freshly drawn blood into a solution which has a specific gravity the same as that of the liquor sanguinis, and which will therefore allow the corpuscles to subside in a mass freed from a considerable portion of the albuminous liquid in which they floated.

This solution into which the blood is to be drawn may be made with salt and water, or sugar and water, the principal object being to obtain it of the same specific gravity as the liquor sanguinis. The corpuscles having subsided through this, and collected as a precipitate, for which purpose a period of rest should be allowed, we are to pour off the supernatant liquid, and again pour some more of the solution of sugar or salt upon the corpuscles, allow these to subside, again pour off, and so on till all the albuminous liquor is removed by the washings. We now have the corpuscles in a form which admits of their being exposed to solution, and which we effect by pouring them as a subsided precipitate into a vessel of distilled water. This breaks their cases by rapid endosmosis, and dissolves the colouring matter contained within. If this mixture be set aside we shall now perceive the white stratum of envelopes and nuclei, which I have before described, forming as a precipitate, while the supernatant liquor is of a bright clear red colour, and is composed of hæmatosine, dissolved in water, and, consequently, presented to us in a favourable condition for examination.

The pure state in which we are enabled to obtain hæmatosine by this plan of operating affords us an excellent opportunity of ascertaining whether the iron contained in the red corpuscle is a component of the hæmatosine, or of the envelope and nucleus; and I may state that careful examination has persuaded me that the whole of the iron of the blood is contained in this red colouring principle, while the nucleus and envelope do

not present the slightest trace of it; and this is a matter of some importance, for though some operators have succeeded in extracting iron from the hæmatosine without interfering with its red colour, it does not the less follow that hæmatosine needs the iron, with which in nature it is always combined, to discharge the offices assigned to it; nor does it follow, because these chemists have obtained a red coloured matter from hæmatosine, that such red coloured matter is the same as the hæmatosine existing in the blood; everything, indeed, that we know, would tend to disprove the correctness of such an idea.

I will here direct your attention to the respiratory function in connection with the red colouring matter of the blood, as it is a subject which has lately much attracted the attention of physiologists. It has been considered by some that several of the facts discovered of late years by experimenters on hæmatosine have tended to cast doubt on its powers as an attractor of oxygen during the respiratory process, and Professor Mûlder has lately altogether discountenanced the idea of hæmatosine changing in character during respiration, but regards it of a similar constitution in arterial and venous blood, explaining the change of colour observed in the blood during its passage through the lungs, and consequent exposure to air, to a change in the form of the corpuscles, and also in part to their becoming clothed with a layer of oxide of protein, which renders them opaque and milky, and, at the same time, renders them of biconcave form by contracting the edge of each surface. This physiologist has stated that solutions of salt render the coagulum of blood of a bright red colour by exosmosing their contents, and thus making them assume the biconcave form, and further states, that when corpuscles are endosmosed and assume the convex form, the colour of the coagulum is darkened in virtue of this opposite condition. This latter state, he says, is brought about if we wash in water the coagulum we have rendered bright by means of salt. Now it is a matter of fact that solutions of salt will act on the corpuscles and produce endosmotic currents, but, unfortunately for the theory above noticed, it matters not whether such solutions endosmose or exosmose the corpuscle, for in both cases they render the coagulum to which they are added of a bright red colour. The rest of this view, which relates to the formation of a milky incrustation of oxyprotein, is purely hypothetical. It is probable that Mûlder never examined the condition of corpuscles reddened by solutions of salt of low specific gravity, for had he done so he would at once have perceived that the rounded form of corpuscles of which he speaks as productive of the dark colour of the coagulum, might

be presented by the corpuscles of a coagulum which possessed a bright arterial tint. One of Mùlder's experiments already alluded to consists in washing with water a coagulum reddened by a solution of chloride of sodium, which, he says, changes its colour to black, by altering the form of its corpuscles from biconcave to convex. You now, from the experiments detailed in my last lecture, know that this washing will break all the reddened corpuscles on the surface, and make them discharge their colouring matter, and so expose the layer of corpuscles beneath, which are dark in colour, owing to not having been acted on, and these have been mistaken for the bright red corpuscles altered by water and changed in colour. Now since change of form can be produced without varying the colour of blood, and as, in fact, the very organization of the corpuscles prevents the possibility of their assuming any but the biconcave form in a fluid of the specific gravity of serum, and as in this fluid they are frequently and commonly known to assume either a vermilion red tint, or a dark colour, according as they are exposed to air or not, we have every reason to believe that these dark and bright red colours depend on changes in the colouring matter, and not on other than chemical conditions. If change of form in the corpuscle were sufficient to account for the change of venous to arterial blood, and this change consisted in the assumption of the biconcave form on the part of the corpuscle, we ought to find, on adding to blood reddened in colour by exposure to air, a solution of chloride of sodium of low specific gravity, and such as would tend to fill out the corpuscles—that the arterial tint would be deadened and made to assume the venous colour, but so far from this being the case, a clot rendered of a bright red hue by exposure to air is still more heightened in colour by the addition of a solution of salt of a specific gravity, which tends to swell out and not to collapse the corpuscles. In these considerations I have allowed, for argument's sake, that strong solutions of salt render the blood-corpuscles of a biconcave form; but this is not by any means the case, as under this influence they become quite empty and flaccid, losing all capability of assuming a form well calculated for the reflection of light, a property which Mùlder ascribes to them under such conditions.

I have not yet fully described to you the hypothesis on which Mùlder accounts for the arterialization of the blood, and the manner in which the absorption of oxygen assists in the production of a scarlet colour. As I stated before, this is, according to his view, an optical phenomenon, and it occurs as follows. During the passage of the venous blood through the lungs, oxygen is absorbed

by the liquor sanguinis, and an oxide of protein formed, which produces on each corpuscle a kind of buffy coat; this buffy coat then contracts, and, becoming puckered at its edges, draws the upper and lower halves of the corpuscles further from each other at the circumference, and thus produces the biconcave form in virtue of which the arterial tint appears as an optical effect. The whole of this is assumption, nor has any part of the hypothesis been supported by any appeal to microscopical or chemical evidence. Let us, on the other hand, remember what we know of the action of colouring matters generally on oxygen, and the many cases we are aware of in which oxygen is rapidly absorbed by coloured substances in the vegetable kingdom, and where a change of their colour is the consequence. The absorbing action of guaiacum is a familiar instance, and one which shows a close analogy to that of hæmatosine.

I have entered thus far into this subject, in order to show what grievous errors an ignorance of minute structure, and neglect of microscopical methods of examination, will lead to, even in those the best fitted to treat of the chemistry of animal bodies. A single moment's examination of blood rendered bright red by a strong solution of salt, would have shown Mùlder a shrivelled and deformed set of corpuscles, instead of the biconcave reflecting bodies he has spoken of.

I have before drawn your attention to the subject of chylification, and the manner in which I believe the chyle contributes the iron it holds in solution to the red colouring matter contained within the blood corpuscle, in order to supply it with that ingredient. Having so far entered on the question of nutrition, I must beg your indulgence while I advert to the question of genesis, and explain some views which I have been led to entertain on this subject, by considering the results I have obtained from microscopic examination of the blood under various conditions. Physiologists are at present at a loss to understand in what part of the system the red corpuscles are generated. The red colouring principle is not to be detected in the lymph, and those who have found traces of it in the chyle would not have done so had they collected the fluid quickly from the thoracic duct, such admixture of corpuscles being purely accidental, and caused by the absorbent action of the divided capillaries on the blood extravasated during the operations necessary for opening the animal. I have frequently obtained chyle perfectly white, and noticed that it became red in the thoracic duct only under the circumstances of extravasation and capillary absorption above noticed. It becomes a question, then, of some importance, to determine the manner in which the red corpuscles are produced,

since they do not appear as coloured bodies, or constituents either of chyle or lymph, nor does microscopical examination show us anything in either fluid at all resembling them in physical characters. Some experiments which I lately made in conjunction with my friend Mr. Samuel Lanc, have, I think, tended to throw considerable light upon this question; and I will proceed to detail the results we obtained, and the plan adopted to test them. The blood, as it is examined ordinarily, between glass and mica, though it is thus preserved in a fluid state for a considerable length of time, is always at a lower temperature than that which it possesses while circulating, and it was therefore to be concluded that under such a condition the actions connected with the nutrition or production of the corpuscle would, in all probability, be interfered with, or entirely suspended.

In order, then, to view the blood as nearly as possible under the conditions it presents while circulating, a specimen freshly drawn was placed under the microscope between glass and mica, and resting upon a bottle of transparent glass filled with water at a temperature of about 110° Fah. By this contrivance the corpuscles could still be viewed as transparent objects, and be kept at a temperature approaching blood-heat, occasionally, perhaps, becoming warmed somewhat beyond 98° or 100°, though this rarely happened, since the metallic fittings of the microscope very rapidly abstracted heat from the bottle. When the corpuscles were examined in this manner, a view was obtained quite different from any that we had before seen. The corpuscles assumed an hour-glass form, in some cases the contraction occurring not in the centre of the corpuscle, but, if the heat was continued, in all cases eventually dividing them into two circular bodies, the one generally being considerably smaller than the other. If the heat was continued for a sufficient length of time, the specimens no longer in any way presented the appearance of blood corpuscles, but having all become divided, the field of the microscope was covered with a multitude of small bodies, the result of the division of the normal blood-corpuscle, as usually seen and described. Now, in order to convince myself that heat had quite completed this division, I examined the resulting small corpuscles by the addition of a strong saline solution, and found that they underwent the changes of exosmosis precisely as I have shown it to occur with the blood corpuscles in their natural state. They seemed, in fact, blood corpuscles produced by division. The next step in this inquiry consisted in examining the blood after violent exercise, when the animal temperature had been increased considerably, and for some

length of time; and on several occasions, when I had opportunities of making such observations, I was enabled to detect a change in the corpuscles very nearly approaching in character to that I have described to occur as the effect of heat artificially applied. Taking these circumstances into consideration, I must confess I am greatly disposed to believe that the blood corpuscles multiply by division; an opinion I consider much strengthened by the fact that the chyle enters the corpuscle to nourish it, and to supply it with iron, but does not appear to contain any organized structure likely to assist in the formation of so complex an organ. The formation of hæmotosine, according to this theory, must occur within the envelope, and in all probability be the result of admixture of chyle with its contents. If we reflect on the results which will follow when this division of the corpuscles has taken place, the first, and perhaps the most important change, is that of their physical condition. We must remember that each corpuscle has now become divided, and that the two masses present a larger surface than they afforded when united in one, and that consequently a larger surface of hæmotosine is exposed to the action of air than was before the case, and more oxygen is therefore attracted into the system. The important bearings of this subject can, perhaps, be but imperfectly appreciated in the present state of our knowledge; we have sufficient data only to show us the rich field for observation that lies before us, and thought is early arrested in threading the intricate windings of the attractive inquiry.

Among the actions of the organism there appears, then, to be an increased attraction of oxygen occurring as the result of the division of the corpuscles of the blood; this absorbed oxygen doubtless contributes to the production of animal heat, and this heat, again, would seem to produce the division of corpuscles. The intermediate links of action associating these phenomena are those of digestion and chylofication. The oxygen attracted will not produce animal heat unless ingesta of a fitting character be exhibited, and unless the chylopoietic organs are in health. Here our subject diverges into many channels of inquiry interesting enough in themselves. To revert, however, to our more immediate object, we now know how necessary it is that the proportion of water contained in the blood should be subject to strict regulation in order that the mechanical results of endosmosis may occur in proper order and proportion for the nutrition of the corpuscle. We must remember that the evils attending the watery degeneration of the liquor sanguinis are both chemical and mechanical: in the

first place, the corpuscles, for reasons which I shall hereafter state, cannot undergo the changes necessary for the production of hæmotosine when they are distended; and secondly, when so filled with fluid they will not circulate freely in those capillaries through which they could before easily pass. These two effects of degeneration from excess of water will be thought sufficiently grave in character, when we remember the important part played by oxygen in the functions of the animal body, since when they are produced together, which is almost sure to be the case, we have a double obstacle afforded to the passage of oxygen as it is contained in the corpuscle through the capillary circulation.

Having considered the genesis of the corpuscles, it becomes a matter of interest to determine the manner in which those bodies are disposed of when worn out, and no longer capable of discharging their wonted functions.

Presuming the old corpuscles to become disintegrated, we must expect either that the debris will exist floating in the liquor sanguinis, or that solution of the nuclei and envelopes will take place, and that they will mix with the colouring matter in the liquor sanguinis. I have stated in my last lecture that if serum be largely diluted with water, we obtain a precipitate, and this precipitate I may now describe as showing, on microscopical examination, a very close approximation in character to that which we can obtain by artificially bursting the blood corpuscles by water, and allowing the debris to subside, and I feel some confidence in the opinion that this is its true character—that it is, in fact, composed of the envelopes and nuclei of the old corpuscles disintegrated.

It will be remembered by those who have studied the chemical history of the blood, that several experimenters have detected traces of iron in the serum. The view I have given of the distribution of the old and broken corpuscles is quite in accordance with the occasional presence of iron in this fluid, and the metal has, in all probability, occurred as an ingredient of the extravasated colouring matter of the blood, and been detected in the serum of specimens in which the destruction of the corpuscles was occurring with an unhealthy degree of rapidity. When blood is viewed under the microscope, we not unfrequently observe bodies on the field to which we are at a loss to ascribe distinctive characters. At one time we may perceive granular forms, at another elongated bodies nearly transparent, and, when once seen, only again to be brought into view by careful adjustment of the instrument. After violent exercise, these bodies are more easily observed, existing then in considerable numbers; indeed, so

much so as to force themselves upon the attention of the observers. These appearances I believe to be due to the presence of debris of worn-out corpuscles, and the increase observed after violent exercise appears to favour this view.

I have now described the anatomy of the corpuscle, noticed its physical attributes, and described that which I believe to be its mode of genesis and destruction.

DR. LEE'S

CORRECTION OF SOME MISSTATEMENTS RESPECTING THE PLACENTA, MENSTRUATION, AND THE CORPUS LUTEUM.

To the Editor of the Medical Gazette.

SIR,

In a recent number of your journal it has been imputed to me that being aware of a scientific error into which I had fallen, in common with several other anatomists, I had not acknowledged it. I shall feel obliged by your inserting the following extract from my published lectures, p. 135, to prove that this accusation is absolutely false.

“The repeated examination of the uterus and placenta in their natural state, under water, and when the uterine vessels were filled with injection, having led to no conclusive and satisfactory results respecting the connection of the placenta and uterus, it occurred to me, soon after the publication of my paper in the *Philosophical Transactions*, in 1832, that the most likely means of discovering the real connection of these parts would be to examine the placenta when the vessels of the uterus were filled with their blood, and coagulated. On the 24th May, 1833, such an opportunity presented itself through the kindness of Mr. Girdwood, of Paddington, and that no doubt might exist in the minds of anatomists as to the accuracy of the description, I requested Mr. Lawrence carefully to examine the parts with me, and draw up an account of the appearances which we observed. It was my wish immediately to have published the memorandum containing an account of these results, but I was dissuaded from doing so by Mr. Lawrence, who thought it better to wait until another opportunity should occur of verifying the observation, and still further elucidating the subject. The facts were, however, immediately made known to Sir Astley Cooper, Professor Owen, Mr. Mayo, and many other members of the profession who felt interested on the subject, and they were thus stated about a month after in the review of Velpeau's *Embryology* in the *MEDICAL GAZETTE*. ‘About a month ago, before

the preparation at the College of Surgeons was examined by Messrs. Stanley and Mayo, we understand that Dr. Robert Lee, in order as far as possible to obviate every fallacy, examined a gravid uterus in the eighth month, in which he had previously coagulated the maternal blood. He was able to satisfy himself and Mr. Lawrence, who was present at the examination, that coagula of the maternal blood extended from some of the openings in the lining membrane of the uterus into canals formed by the deciduous membrane on the margin of the placenta. These vessels or channels in the decidua could be traced only a short distance along the margin of the placenta and between the lobes."

It has likewise been falsely imputed to me that I have attempted to appropriate to myself the theory of menstruation by Dr. Power. The following extract from my paper on the Diseases of the Ovaria, published on the 1st April, 1833, in the *Cyclopædia of Practical Medicine*, will show that this accusation is also groundless.

"Dr. Power has likewise conjectured that an ovum escaping from the ovary at every monthly period is the cause of menstruation, which he has defined to be 'an imperfect or disappointed action of the uterus in the formation of the membrane (decidua) which is requisite for its connexion with the impregnated ovum.' This hypothesis does not appear to have been formed from actual observations on the ovaria during menstruation, as Dr. Power has made no allusion to these in his work, and does not state that he has ever examined the body of any individual who died with the menses upon her. That an ovum, by which is usually meant an embryo enveloped in membranes, does not pass from the ovary during menstruation, is evident from the fact that an ovum is never formed but as a consequence of impregnation, and that conception does not take place at the menstrual period. The facts which have now been related render it, however, extremely probable that all the phenomena of menstruation are dependent upon, or are connected with, some peculiar changes in the Graafian vesicles, in consequence of which an opening is formed in their peritoneal and proper coats. Whether an entire vesicle, or only the fluid it contains, escapes through the opening at the period of menstruation, further observations may hereafter determine. There is no proof whatever that an ovum passes along the fallopian tube into the uterus during menstruation, and it is not clearly established that this takes place even subsequent to conception."

Surely, after having published these observations, expressing the strongest doubts of the

truth of Dr. Power's hypothesis, I could never have attempted to appropriate to myself as my own his theory of menstruation, nor claimed the illustration of that theory. No such attempt was ever made by me, nor did it ever enter my imagination to do so. To Dr. Girdwood, of London, Dr. Paterson's relative, belongs unquestionably the undivided honour of claiming the illustration of Dr. Power's theory.

Dr. Craigie has been led to make an erroneous statement in the same number of the *MEDICAL GAZETTE*. He says, "I have examined the originals of all the letters which were addressed by Dr. Lee to Dr. Bowman and Dr. Paterson on the subject of the corpus luteum, submitted by Dr. Bowman, in May, 1844, to Dr. Lee, for examination, and which letters, excepting two to be afterwards specified, were published in the 161st, or October number, of the *Edinburgh Medical and Surgical Journal*, and the following I find to be the result. The letters are *eight* in number." The number was ten, and not eight, as here stated by Dr. Craigie; there were three to Dr. Paterson, and seven to Dr. Bowman. The following are the dates of these seven letters to Dr. Bowman:—

1. 13th May, 1844.
2. 22d June —
3. 26th June —
4. 30th July —
5. 6th Aug. —
6. 8th Aug. —
7. 24th Aug. —

Dr. Craigie has made no allusion to the two last of these seven letters, and was, I must believe, kept in total ignorance respecting them. From whatever cause, however it has arisen, there can be no doubt that his statement is erroneous, and there can now be no difficulty in explaining why these letters were not published in the mutilated correspondence in the *Edinburgh Medical and Surgical Journal*, and why Dr. Craigie was not permitted to see them. They are as follows;—

4, Saville Row, 8th August, 1844.

My dear sir,—I have again to request that you will by return of post inform me whether you did not receive from me more than two letters relating to the preparation in question. The dates are of no importance, but it is of the greatest that I should receive a positive answer to my simple question. You cannot fail to remember the number of my letters.—I remain, dear sir, faithfully yours,

Dr. Bowman.

ROBERT LEE.

In reply to this letter, Dr. Bowman states on the following day, the 9th August: "*Dr. Paterson has all your letters referring to the preparation in his possession,*

and my memory will not allow me to speak positively.' On the 10th, it will be seen below that Dr. Bowman's memory was restored to him.

The following is the last letter addressed by me to Dr. Bowman, and was suppressed. It will be seen that it contains a distinct request to be informed respecting the fate of my first letter.

4, Saville Row, 24th August, 1844.

My dear sir,—You have now had abundance of time to refresh your memory, and can tell me no doubt everything respecting the *first* letter I wrote to you, and whether it was impounded at Monkwearmouth, or actually sent forward to Leith, as you stated in a former letter. Your friend in the north threatens to publish the correspondence between you and me. I hope you will take care before he does so that my *first* letter is forthcoming, and that it is published with the others. Truth has nothing to fear. A man who conscientiously tells the truth has only to go on in his course, but a man who departs from the truth has every thing to dread.

Mr. Dodd will again soon call upon you to receive from you those explanations which are evidently required to clear your character from the suspicions under which it must lie until you reveal all the circumstances connected with this affair. Your first letter to me led me to form a very favourable opinion of your candour and integrity. I pray that my good opinion of you may continue unchanged.—I remain, &c.

ROBERT LEE.

Dr. Bowman.

It is now proved, that four letters written by me to Dr. Bowman were suppressed by Dr. Paterson in the correspondence which he published in the *Edinburgh Medical and Surgical Journal*. Dr. Paterson's apology for suppressing the first of these letters, for denying its existence when actually in his possession, and then acknowledging its existence but withholding a copy from me, is contained in the following words. "It is necessary for me," he says, "to add a few words regarding the letter of the 13th of May, about which Dr. Lee has said so much. Dr. Lee states that no copy of it was sent to him. Its date, however, was forwarded to him, and the general tenor of its contents, as well as the fact that it contained no opinion on the preparation. Dr. Lee, possessed of this information, still writes for a letter between the 13th and 22d May, a letter which had no existence. He now, however, says that it was the letter of the 13th May that he all along wanted. To my mind it appears, that had Dr. Lee wanted a copy of his letter of the 13th May, (with the date and tenor of which he had already been furnished) he would have writ-

ten for it, but, instead, he asks for one between the 13th and 22d May, and yet now says that it was the letter of the 13th that he referred to. Such conduct appears to me inexplicable, and I leave the reader to draw his own inferences regarding it."

A perusal of the following letters, and a comparison of their dates, will at once expose the entire falsehood of this statement.

It will be seen that I was *not* in possession of the information respecting my letter of the 13th May, when the first two of the following letters were written.

Saville Row, 6th August, 1844.

My dear sir,—Will you have the kindness to inform me by return of post whether or not you received a letter from me respecting the preparation of the corpus luteum, between the 13th and the 22d of May.—I remain, yours very truly,

ROBERT LEE.

Dr. Bowman.

London, 4, Saville Row, 5th Aug. 1844.

Dear sir,—I wrote another letter to Dr. Bowman, before the 22d May, 1844, of which you have not forwarded a copy to me. I am much obliged to you for the copies of the *two* you have sent, and I trust you will feel entirely satisfied with the account which Mr. Wharton Jones will give in the next number of the *Medical Gazette* of his microscopic examination of the body in question.—I remain, dear sir, very faithfully yours,

ROBERT LEE.

To Dr. Paterson.

Leith, 10th August, 1844.

Dear sir,—I beg to acknowledge the receipt of your letter dated August 5th, which would have been replied to sooner, had it not been that I expected, ere this, to have heard from Dr. Bowman in answer to a letter sent to him immediately after the receipt of yours. You *accuse* me of having kept a letter which you wrote to Dr. Bowman, of a previous date to those copies of which were sent to you. In reply to this *accusation*, I have to state that I never received any letter of yours from Dr. Bowman of a prior date to those the copies of which were sent you. In addition, you make no reference to a previous letter in the first one I received of the 22d May, and I am convinced, that, had any previous letter arrived, such would have been immediately communicated to me by Dr. Bowman. As soon, however, as I receive an answer from Dr. B. I will write to you.

I shall be glad if Mr. Jones's statement of the question in dispute between us shall be satisfactory to me.—I have the honour to remain, your obedient servant,

ROBERT PATERSON.

Dr. Robert Lee, London.

No explanation has yet been given of the falsehood contained in this letter.

Leith, 12th August, 1844.

Dear sir,—I presume that you will by this time have heard from Dr. Bowman himself regarding the number of your letters to him. I may state, however, that they were three in number. The *first*, dated May 13, acknowledges your receipt of the preparation; the *second*, dated May 22, contains your opinions regarding it; and the *third*, dated June 26, accompanies the return of it. These, Dr. Bowman distinctly states, were the only letters received from you in connexion with the preparation sent you.

I have just seen Mr. Jones's description of the preparation, and more especially of the corpus luteum in question, in the *Gazette of Saturday last*. It contains one or two most important errors, which it will be necessary to have corrected. Before doing so, however, I am anxious to know if Mr. Jones's letter contains all the statements you propose to make public regarding your unjust criticisms on the case, and as more especially stated by me in a former letter.

I shall feel obliged by your communicating to me, with your earliest convenience, if any further statement on the subject is to be made public.—I have the honour to remain, your obedient servant,

ROBERT PATERSON.

Dr. Robert Lee, London.

It will be seen that in this letter there is not a word said respecting the tenor of my letter of the 13th May, "nor is the fact mentioned that it contained no opinion respecting the preparation." What it did contain of importance is, however, entirely omitted.

Another false statement, made in the same number of your journal, is, that "Dr. Lee has thus first violated his written promise by not publishing a confession of his error in the pages of the *Medical Gazette*." No such written or verbal promise was given by me; "I shall feel the greatest pleasure," I said, "in communicating to the *Medical Gazette* the grounds upon which I was led to conclude that it was a true corpus luteum which was submitted to me by Dr. Bowman. Before, however, doing this, and complying with the request contained in your letter, it will be necessary for me carefully to examine your description of this body in the *Edinburgh Medical and Surgical Journal*." The publication of Mr. Wharton Jones's microscopical report fulfilled what was here promised, and the examination led to the discovery that if the ovary sent to me from Monkwearmouth were the ovary of the lamplighter's wife (which several distinguished anatomists still greatly doubt), Dr. Paterson's description of it in the *Edinburgh Medical and Surgical Journal* was nothing but a mass of error*.

* The preparation of the uterus and appen-

"I may state once for all," says Dr. Paterson, "in reply to various charges which Dr. Lee makes in the communication referred to, that Dr. Bowman, who sent the preparation to him, *knew nothing whatever* of its history until after Dr. Lee's opinion of it was delivered, and that the preparation itself was taken out of a preparation jar, where it had been preserved in spirits, wrapped up in clean linen rags steeped in spirits, and put into a tin canister, to enable it to be sent through the post. In this way it must have reached Dr. Lee, for it was never even opened at Monkwearmouth."

Let the reader compare this with the following letter from Dr. Bowman to me, and observe the unenviable position in which these two individuals are placed by their contradictory statements. Will Dr. Bowman produce the correspondence which had previously taken place between him and Dr. Paterson, and thus vindicate his character from this direct attack upon his veracity? There is no man who will believe in Dr. Bowman's innocence until the whole of the letters which passed between him and Dr. Paterson before the 27th of May are openly produced, nor will any man place the slightest reliance on the preceding statement made by Dr. Paterson until this has been done.

Monkwearmouth, 27th May.

My dear sir,—I feel exceedingly obliged and grateful for the attention and trouble you have taken in examining and giving me your opinion of the preparation I took the liberty of forwarding to you. It is very gratifying to me that you, whose opinion bears such weight in the medical world,

dages of the lamplighter's wife belonged originally to Dr. Simpson, Professor of Midwifery in the University of Edinburgh. On the 9th Nov., 1844, I sent to Dr. Simpson a copy of my last Paper on the Structure of the Corpus Luteum, and its Value as a Test of Early Pregnancy, (*MEDICAL GAZETTE*) with the following note. "It appears that the preparation referred to in the accompanying paper belongs to you. Were you aware for what purpose it was to be used when you gave it out of your possession into Dr. Paterson's hands, to be sent surreptitiously to me by W. O. Bowman, M.D. Monkwearmouth?" Dr. Simpson stated in reply, that two years ago he had given the preparation to a gentleman who set a higher value upon it than he did, in consequence of the uterus containing a beautiful decidua. As there was no decidua in the uterus sent to me from Monkwearmouth, it is now very necessary that the members of the profession should hear something further respecting this part of the preparation. Dr. Simpson would gratify the wishes of many who have taken an interest in this discussion, if he would not merely name the gentleman to whom he gave the preparation—the present possessor of this beautiful decidua—but name those, if he is able, through whose hands the preparation has passed during the last two years. He would gratify them still more by stating if he knows who the professional friends were who advised Dr. Paterson to adopt the stealthy plan of getting a candid opinion.

should have come to the same conclusion *I had already formed*, namely, that it is a true corpus luteum.

I have communicated with my friend, who will be happy to let you retain the half of the ovary as you request, but as he has some intention of publishing the case at some future period, he would wish you to return the remainder as soon as convenient.

I take this opportunity of returning you my sincere thanks for your kindness and attention.—I have the honour to be, your obedient servant,
H. O. BOWMAN.

Dr. Lee.

The author of the preceding ignorant and unfounded imputations, who, on the 9th May, 1844, expressed the "highest confidence in my opinion," thus expressed himself in your journal on the 14th February, 1845:—"I feel that I owe a statement by way of apology to my professional brethren for the means which I adopted to procure the delivery of a candid opinion on the preparation in dispute from Dr. Lee; for the following reasons I considered myself justified in having recourse to a plan with Dr. Lee that I never would have had recourse to with any other member of the profession." The "highest confidence in my opinion," entertained on the 9th May, 1844, suddenly vanished, when it was unexpectedly discovered that I had detected the truth, though most artfully concealed, and that the gross deception which had been practised would be completely baffled and exposed. The panegyric and the attack are held in the same estimation by me, and I know that they are held so by all the honourable members of the medical profession.

The importance of a knowledge of the structure of the corpus luteum, and of the distinction between true and false corpora lutea in medico-legal inquiries, cannot, I conceive, be better illustrated than by the report of what took place at the Medical Society of London, on the 3d February last, which was published in the *Lancet*, March 1, 1845, p. 245.—I am, sir,

Your obedient servant,

ROBERT LEE.

4, Saville Row, March 14, 1845.

EMPALEMENT,

(CAUSED BY AN IRON SPINDLE PENETRATING THE LEFT BUTTOCK, AND COMING OUT BY THE RIGHT OF THE NAVEL,)

WITHOUT VISCERAL INJURY.

By M. BESSEMS.

A LAD, aged 14 years, of middle stature, working with his father, a silk winder, got up upon a bed about four feet high; at the side there happened to be a wooden block

into which were inserted by their handles, at some distance apart, two axes of the reel, iron spindles, blunt at the point, a foot long, and of the thickness of a large quill.

In this dangerous position his left foot slipped and he fell. After the fall, during which he experienced no particular pain, his body was inclined forwards and to the left, supported by the left shoulder resting against the wall and by the feet upon the ground; the thighs were slightly bent upon the pelvis.

On attempting to rise he felt himself pinned by the buttock, at the same time perceived with surprise rather than fright one of the axes protruding from the belly at the side of the navel, having moreover perforated in this situation his shirt and trousers. Maintaining remarkable *sang-froid*, he detached the axis of the block, and thus transfixed, walked down about a dozen steps of a staircase to call his mother, who pulled out the spindle, and then waited the arrival of a surgeon.

The axis acquired only a slight curvature at the line of junction with the handle.

At his admission into the hospital three days after the accident, this patient presented merely two small round wounds; one on the anterior wall of the abdomen about three-quarters of an inch to the right of the navel, in the direction of a line drawn from thence to the anterior superior iliac spine; the other in the fold of the left buttock about two and a half fingers' breadth from the anus. These two wounds, surrounded by a reddish circle, furnished a slight exudation.

The pain, which the preceding evening had been vague and radiating over the whole abdomen, was, on admission, very trifling, and confined to the margin of the front wound. Otherwise there was no morbid symptom; the belly was supple; appetite, digestion, stools, and urine, natural; not the least febrile reaction.

This favourable condition lasted up to the period of the patient's dismissal, twenty days after the casualty.

It would appear in this case that the spindle after penetrating the left buttock at two and a half fingers' breadths from the anus, must have traversed diagonally from below upwards the left half of the pelvic hollow and a part of the abdominal cavity in order to have forced a way out by the right of the navel. The anatomical disposition of the peritoneum is such that in this course the spindle must have necessarily rent this serous sac. Yet, this lesion, reputed so serious by surgical writers, was not followed by any mischief.

Another remarkable particular connected with the above fact is the absence of visceral

injury. If it be reckoned that during the vertical position in which the lad was when the thing occurred, the intestinal convolutions must have filled the entire pelvic cavity, it is difficult to conceive how an iron spindle could have passed through this cavity amid the convolutions without doing any hurt.

The blunt point of the instrument and the round lubricous conformation of the bowels, are apparently the circumstances to which so fortunate a result may be ascribed.—*Annales de la Société de Médecine d'Anvers*, Janvier 1845. p. 43.

The manipulation of turning was easily accomplished, the waters not having come away.

The womb retained after delivery, at its upper margin, a certain depression, which made the angles more marked than this margin forms in uniting with the lateral margins, proving the persistence of the deformity in the empty state of that viscus.—*Annales de la Société d'Anvers*, Février 1845, p. 89.

COLON STRANGULATED BY THE MESO-COLON.

SINGULAR DEFORMITY OF THE WOMB, INDUCING ARM PRESENTATION OF THE CHILD IN THREE CONSECUTIVE LABOURS.

BY DR LECLUYSE.

CALLED the 4th of August, 1844, to a third labour, in the instance of a woman of small stature, whose first two deliveries had required the turning of the child on account of the arm presenting, I was much surprised to find a recurrence of the same. I was unable at the moment to explain this frequency of transverse presentation, but on passing one hand over the abdomen while taking a pain with the other, the upper margin of the womb was felt so low and so near the pubis as to lead to the belief that this organ was only half developed, or, at all events, in a state of anteversion, or other faulty position.

Upon examining the abdomen more carefully, I ascertained that these suppositions were groundless; and it was only by comparing the little elevation of the womb with the great development of the flanks, that deformity of the organ of gestation could be surmised. In effect, the sides of the belly were evidently far more prominent than ordinary, and passed beyond the hips so as to cause a breadth which contrasted singularly with the small stature of the woman.

The womb, instead of being pyriform in the vertical sense, presented, as it were, a sort of ellipsoid, of which the extremities of the greater axis corresponded respectively to the centre of the flanks; it had thus gained in breadth what it lost in height. To this strange anomaly I would ascribe the frequency of the horizontal position of the fœtus, the greater diameter of the fœtal ovoid being in perfect parallelism with that of the elliptic cavity of the womb.

The genital parts were in other respects natural; the neck of the uterus alone seemed a little more raised, which might depend on the absence from pressure of some projecting portion of the child.

DR. GILMAN DAVIS, of Portland, Me., relates in the *Boston Medical and Surgical Journal*, (Dec. 11th, 1844,) an interesting case in which fatal strangulation of the colon in an aperture in the meso-colon occurred. The subject of the case was a gentleman, twenty-six years of age, who was attacked on the 13th Oct. 1843, with paroxysms of pain in the epigastric region, without tenderness; but with remarkable tonic rigidity of the abdominal muscles, and constipation. By the use of cathartics, enemata, and opiates, after three days suffering, evacuations were produced from the bowels, and the other symptoms then yielded.

The patient, except being troubled with constipation, enjoyed moderate health after this until the 5th of May, 1844, when he experienced an attack similar to the first. There was superadded to the previous symptoms, constant vomiting; every thing swallowed was instantly rejected. There was no thirst; the firmest pressure on the abdomen caused no pain; there was extreme restlessness and nervous agitation, and the patient complained that there was a stoppage in the epigastric region, and said he should feel better if he could only have an evacuation from his bowels. Various remedies were employed, without, however, the least benefit; the patient got worse and worse, and died midday, May 9th.

On *post-mortem* examination a large knuckle of intestine, of a deep port wine colour, composed of thirteen inches of the colon, was found strangulated in an aperture about the size of a quarter of a dollar in the meso-colon. From the strangulated intestine to its termination in the anus, measured four feet. The strangulated intestine was in a complete state of mortification. The aperture was round, with even edges. No reasonable conjecture could be formed as to the cause of its formation."—*American Journal of the Medical Sciences*.

MOVEMENT IN THE PROFESSION.

At a meeting of the medical profession of York, held upon the 19th inst., thanks were expressed to Sir James Graham for allowing ample opportunity of considering the new bill. Several of the alterations therein contained were fully approved. It was recommended that a clause be introduced, authorizing the representation of general practitioners in the Council of Health; that the Apothecaries' Act be entirely repealed. In the opinion of the meeting, the proposed measure will have a degrading influence upon the members of the College of Surgeons, by requiring them to register as licentiates in medicine and surgery; and the institution of a special instead of a general examination in midwifery will give rise to invidious distinctions. It was further suggested, that, in any charters granted to the Colleges of Physicians and Surgeons, corporate rights should be secured to all the members of the said Colleges, and that the fellowship be open to every member who shall have complied with the regulations, and passed the prescribed examinations; that it should be lawful for the same person to register as both physician and surgeon; and that a more summary mode of preventing illegal practice be ingrafted on the bill, than the one proposed in Clause 35.

Copies of protests against the proceedings of the Council of the College of Surgeons, in the matter of the fellowship, have reached us; one is from Manchester and Salford, another from West Somerset, and a third from Gloucestershire.

The following are the avowed sentiments of the National Association of General Practitioners in Medicine, Surgery, and Midwifery:—

"They require a College—They wish to build a College for themselves—They desire to have a Government on the representative principle, totally unshackled by the customs and laws of any city guild—to make their own bye-laws, to appoint their own examiners, and to be authorised by law to examine and certify as to competency to practise—not as apothecaries—not in medicine alone—but as general practitioners in medicine, surgery, and midwifery. They desire not to interfere with the College of Physicians, or College of Surgeons, but, on the contrary, to hold them in the same estimation they have ever done; but they protest against being rendered the mere offset, the mere licentiates of either College; they call for an independent incorporation, with equal rights and privileges, and to this they feel that their own and the public interest justly entitle them."

APOTHECARIES' HALL.

Gentlemen who have obtained Certificates, March 20.—Joseph Kaye, 31, Bedford St., Strand.—Arthur Charles Morse, Ealing, Middlesex.—Samuel Sumner Dyer, Ringwood, Hants.—Frank Hatchard, London.—James Taylor, Manchester.—George Vernon Driver, Lower Grosvenor Place.—Henry Pitt, Walsall.—Allan Major, Derby.

MORTALITY OF THE METROPOLIS.

Deaths from all causes registered in the week ending Saturday, March 15.

ALL CAUSES 1069
SPECIFIED CAUSES 1066

I.—Zymotic (Epidemic, Endemic, and Contagious) Diseases, 157; among which, of—

Small Pox	32
Measles	23
Scarlatina	23
Hoop-cough	39
Croup	10
Thrush	3
Diarrhoea	3
Dysentery	0
Cholera	0
Influenza	1
Typhus	21

II.—Dropsy, Cancer, and other Diseases of uncertain or variable Seat, 95; among which, of—

Inflammation	0
Dropsy	29
Scrofula	1
Cancer	13
Atrophy	11
Debility	24
Sudden Deaths	6

III.—Diseases of the Brain, Spinal Marrow, Nerves, and Senses, 179; among which, of—

Hydrocephalus	27
Apoplexy	33
Paralysis	25
Convulsions	62
Insanity	2
Delirium Tremens	2

IV.—Diseases of the Lungs, and of the other Organs of Respiration, 388; among which, of—

Pneumonia	101
Hydrothorax	11
Asthma	46
Phthisis or Consumption	166
Diseases of the Lungs, &c.	16
Diseases of Heart and Blood-vessels	40

V.—Diseases of the Stomach, Liver, and other Organs of Digestion, 73; among which, of—

Teething	16

Medicine and the Collateral Sciences.

FRIDAY, APRIL 4, 1845.

GULSTONIAN LECTURES,

Delivered at the Royal College of Physicians,

By G. OWEN REES, M.D. F.R.S.

Assistant-Physician to Guy's Hospital, and Physician to the Pentonville Prison.

HAVING, sir, had the honour, in two previous lectures, to draw your attention to the general chemistry and anatomy of the blood, I shall proceed on the present occasion to consider certain physiological and pathological conditions, having reference principally to the physical state of the fluid as affected by its dilution; the result of variation in the proportion of water entering into its constitution. I have already noticed the condition of the blood corpuscles as they circulated, and the equality in specific gravity between their fluid contents and that of the liquor sanguinis as the necessary result of stasis between fluids separated by membrane, which is the case with the red coloured liquor contained within the envelope, and the liquor sanguinis without. I have already shown that the addition to the liquor sanguinis of any solution which changes its specific gravity, when mixed with it out of the body, exerts on the blood corpuscles an immediate action, owing to the establishment of endosmotic currents through their membrane. I have also shown that these effects will vary according to the specific gravity of these saline or saccharine solutions, and that strong solutions always collapse the corpuscles, while weak solutions, on the contrary, always distend them. Now since there are large discharges of water constantly occurring during the various processes of excretion and secretion, connected with the healthy actions of the organism, and as this water must of necessity be supplied by the blood, it is a matter of some interest to ascertain whether or not the liquor sanguinis varies so greatly in its specific gravity at different times, and under varying condi-

tions, as to change the form of the corpuscle, and thus alter its relation to the blood-vessels or capillaries,—this being an important matter for the physiologist, and one which, if determined in the affirmative, may be expected to assist in throwing light on many questions of interest to those engaged in pathological inquiries. It was thought desirable, in order to determine this question, to take advantage of a condition under which a large discharge of water had occurred; and for this purpose the skin was chosen as the emunctory, its action being more easily and safely induced than that of any other of the excretory surfaces.

During the last summer I had opportunities of examining microscopically the blood of three young men immediately after they had partaken of violent exercise, and had perspired very freely, and in every case observed that the corpuscles were very much thinned, and presented the appearance assumed by those bodies when subjected to the action of solutions exceeding the liquor sanguinis in specific gravity. In fact, the liquor sanguinis had lost water through the cutaneous surface by transpiration, had therefore become increased in density, and acted upon the corpuscles in the circulation so as to exosmose their contents. It becomes now a matter for consideration to determine how these corpuscles again acquire their normal condition of stasis, and again become surrounded by a fluid of healthy specific gravity; but no great difficulty is in our way, for it is easy to imagine that the water supplied to the system, by gratifying the calls of urgent thirst, will rapidly find its way into the circulation, react on the corpuscles, and, by a series of endosmotic changes, rapidly reduce both them and the liquor sanguinis to the normal standard of density. There can indeed be but little doubt that this occurs, not only from what we know of the physical nature of the corpuscle, but also of the state of the blood in disease, to which I shall presently allude.

The return to the normal standard is doubtless rapidly effected in health; the stomach receives water into the system, and distributes it through the blood. The skin and kidney excrete water in large proportion, when it may have been detained from some accidental and casual cause in the circulation, or perhaps for some special object; and the lungs contribute in no small degree to the perfection of these oscillatory actions essential to health.

It may be as well to describe in this place the result of an experiment made on the living animal, having reference to the state of the blood corpuscles while circulating in the vessels, as it proved that they are subject to the same physical laws, while thus circumstanced, as when out of the body. In a former lecture, when describing the manner in which the blood corpuscles removed from the body became inflated according as fluids of high or low specific gravity were added to them, I spoke of the destructive action of water, which burst the cases of the corpuscles, by causing rapid endosmosis. Now the phenomena of collapse and distension may both be observed in the human subject; but it became necessary to perform an experiment on one of the lower animals, in order to determine whether blood corpuscles could be burst by the addition of water while circulating in the vessels. To solve this question the jugular of a healthy terrier was first laid bare, and about six ounces of blood drawn from it; this was set aside to coagulate. Six ounces of pure water were now thrown carefully into the circulation, after which the animal was allowed to rest for about five minutes. About six ounces more of blood were then drawn away, and set aside to coagulate, in order to compare it with that which had been drawn previous to the injection of water. Now, presuming the blood corpuscles to be burst by water in their natural condition circulating in the vessels, in the same manner as when removed from the body, the serum of blood, as obtained by the coagulation of that specimen drawn after the injection of water into the jugular had been made, ought to be sanguinolent, because the colouring matter which, in the natural state, is retained within the membrane of the corpuscle, would be dissolved throughout the liquor sanguinis, owing to the bursting of the membrane; and it would appear in the serum, as shown by its colour. Such a result was obtained; the specimen of blood drawn from the dog before the injection of the water was of its ordinary pale straw colour, while that drawn after the injection of water was strongly sanguinolent, that is, tinged by the red colouring matter of the corpuscles, proving that water had acted on those bodies while in the circulation precisely in the same

manner as when they are removed from the body. In fact, the endosmotic laws are in action during the circulation of the corpuscles even to the production of extreme effects.

It is, however, improbable that the destruction of the corpuscles by bursting, as the result of watery admixture, should ever occur as a pathological result; for even were it possible that the animal solutions with which the corpuscles might come in contact were degenerated so as nearly to approach the specific gravity of water, we must recollect that the pathological change leading to that state is a gradual one, and that consequently the contained fluid of the corpuscles will too nearly approach in specific gravity to the degenerated fluids, to occasion that rapid endosmosis which would cause the membranes of the corpuscles to burst. The specific gravity of the liquor sanguinis is doubtless maintained at the normal standard by the regulating power of the skin, lungs, and stomach, as exhalers and absorbers of water, in the healthy state of the body; but let us consider what we must expect if disease supervene, and these compensating actions are no longer capable of exerting their beneficial influence. If, from any cause, the watery part of the blood fail to pass off in healthy proportion, or if a similar condition be brought about by too abundant a discharge of the solid constituents of the liquor sanguinis, and the blood contain an excess of water in consequence, then the corpuscle will, by a continued contact with the degenerated fluid, necessarily have its contents lowered in specific gravity also, and the solution of hæmotosine contained within it will be abnormally dilute. But this is not all: we know that there are a set of changes which must necessarily occur between the chyle and the blood corpuscles in health, owing to the difference in specific gravity between that fluid and the contents of the blood corpuscles, and in virtue of which a large proportion of the chyle is permitted to enter through the membrane and mix within it. Now the chyle is of less specific gravity than the contents of the blood corpuscle in health; and the nearer the contents of the corpuscle approach to the specific gravity of the chyle, the less interchange will take place between the two fluids, in accordance with the endosmotic law, and the less iron will enter the corpuscle to assist in the formation of hæmotosine. Thus genesis and the nutrition of the corpuscles is interfered with, and the blood is totally deranged. From this watery degeneration, then, we have two evils arising: firstly, the solids are supplied with a dilute liquor sanguinis; and secondly, the corpuscles attract less oxygen into the system than in health, there being fewer of them, and those existing containing only a diluted hæmotosine.

Diseases characterized by excess of water in the blood, so far as we are at present acquainted with them, are productive of that expression of countenance to which the term anæmia has been applied. Now it is well known that anæmia can be produced not only by direct loss of blood, but by an excessive discharge of any fluid from the system which contains as an ingredient the solid matters of the blood; nor is it necessary that red corpuscles should form part of the discharge in order that this effect should be produced: long-continued leucorrhœa will occasion it; and the discharge of albumen with the urine is a fertile cause of anæmia. The anæmia which is produced by loss of blood is in all probability accompanied by absorption of water through the skin, an action which, did it not occur in severe floodings, would probably greatly increase the number of deaths by this disease. The extreme and distressing thirst observed in such cases indicates the necessity for the presence of water, the immediate use of which is probably to supply a bulk of fluid to replace the blood lost, and enable the heart to contract—to supply it, in fact, with something to contract upon. The thirst, arising as I have described, is frequently greatly relieved by the application of water to the surface. Sponging the skin at intervals with water has been found to allay this distressing symptom; and it appears from this fact more than probable that, under the conditions of system above alluded to, the skin becomes an active absorbent organ; and that the use of water, as applied to the surface, should be considered as a valuable remedial measure, directly influencing the heart, and not merely as a means of alleviating the symptom of thirst.

While on this subject I may perhaps be permitted to theorise on the manner in which hæmorrhage is occasionally restrained, or rather allude to the manner in which its suppression is probably assisted by the conformation and peculiarity of structure of the blood corpuscles. When large quantities of blood exude from the capillaries, and water is absorbed by the skin, and taken in by the stomach to satisfy thirst, the specific gravity of the liquor sanguinis must become lessened. The immediate effect of this will be, that the corpuscles of the blood become endosmosed and swollen; and this will take place in proportion varying directly as the rapidity and quantity of the flow of the blood lost. Corpuscles which could before circulate through capillary vessels, have now, owing to this endosmotic change, assumed a form and acquired a degree of hardness, *from mechanical distension*, which will preclude the possibility of their entering tubes of the same calibre as before; and the corpuscles,

the part of the blood immediately necessary to life, will thus be assisted in remaining in the circulation, and, moreover, will tend to exert a mechanical plugging action on the mouths of the bleeding vessels. In passive bleedings from mucous surfaces, it seems highly probable that the conditions I have described tend greatly to the preservation of life, by assisting in the suppression of hæmorrhage. We can by this theory also explain the excessive and persistent pallor occasionally noticed in anæmia; for the enlarged condition of the blood corpuscles will prevent their circulation in those capillaries of the skin and mucous surfaces which before they could readily permeate; and thus another immediate cause for the anæmiated skin is added to that arising from a positive deficiency in the number of corpuscles of the blood. In considering the remoter causes for anæmia, it would appear that the most common are those quite unconnected with hæmorrhage, in which, indeed, scarcely any of the entire blood is lost, but where the constituents of the liquor sanguinis only are allowed to escape in excess, either from mucous membranes, or the secreting surface of the kidney, in more than healthy proportion.

Among anæmiated patients we shall find a large number who have been, or are, the subjects of leucorrhœa, or some form of discharge which contains one or more of the proximate elements of the blood as an ingredient.

When the discharge which is the cause of anæmia consists in part of red particles, we can well understand the pallor of countenance, and deficient colour of skin, characteristic of the disease, inasmuch as a large quantity of colouring matter is removed from the circulation; but the deficient proportion of red particles observed in those cases of anæmia caused by the abstraction from the blood of albumen, either in the form of leucorrhœal discharge, or as it exists in some diseased forms of urine, requires explanation, inasmuch as it must necessarily be a secondary effect, and one not so immediately palpable on a first view. The decrease in the proportion of the corpuscles is, I believe, brought about as a consequence of the decrease in the specific gravity of the liquor sanguinis, which by degrees renders their contained liquid of a less specific gravity than it should be, thus interfering with the proper changes which should occur between this contained liquid and the chyle poured in by the thoracic duct. It may perhaps occur, that when the blood becomes degenerated and watery, in the manner I have described, that the chyle partakes of the condition, and that therefore it still maintains a specific gravity proportionally lower

than that of the contents of the corpuscle. It is more likely, however, that the balance of health, as regards the density of these fluids, is considerably disturbed; but whichever may be the case, it is obvious that, under these diseased conditions, the blood corpuscles cannot be supplied with iron, as before, if we presume dilution of the chyle to take place in proportion to the degeneracy of the liquor sanguinis; for the iron will be in dilute solution.

It must have occurred to all who are in the habit of attending to the diseases of females, to have observed cases of chlorosis in which the anæmiated condition was prominently marked, and in which no history could be obtained showing that hæmorrhage, discharge, or flux, in any form, had taken place, to rob the blood of its solid matters. Notwithstanding this circumstance, however, the blood in such cases has become greatly impoverished; the blood corpuscles are in deficient proportion, and there is a coolness of the surface, with a tendency to blueness under the nails, indicative of deficient capillary circulation. It seems probable that we have here an imperfect excretory action on the part of the skin, as a cause of mischief, and that the superfluous water is not exhaled by that emunctory as it is in health, and that too large a proportion of it is consequently retained in the circulation, which will lead to the same evils as though the blood had lost its solids by albuminuria or leucorrhœa. Retention of water, it is obvious, will degenerate precisely in the same manner as loss of solids, and will decrease the specific gravity of the liquor sanguinis.

I do not believe that the powerful action of the skin, lungs, and kidneys, as adjusters of the specific gravity of the blood, has ever been taken into account sufficiently. We know that healthy blood has a fixed specific gravity; that if the fluid be drawn from ten healthy men, the specific gravity of the liquor sanguinis and serum will be almost identical; and yet let us remember how large a quantity of fluid is being constantly poured into the circulation, and which must be rapidly excreted, or the most mischievous consequences will result. Unless we fully comprehend the rapidity and extent of this excreting action, we shall scarcely be inclined to admit the importance of cutaneous exhalation as a preservative, and the dangers attendant on its suppression. I may here allude to those cases of anasarca which follow scarlatina, and in which it seems almost certain that the interrupted action of the skin as an excretor of water degenerates the liquor sanguinis by decreasing its specific gravity, and brings about the symptom of effusion, an evil which, from some observation and experience in the disease, I am inclined to believe is frequently to be avoided

by the use of mild saline purgatives during the prevalence of the eruption and the period of desquamation following it.

This plan of treatment ensures a moderate aqueous discharge from the intestinal surface, and tends to preserve the healthy specific gravity of the liquor sanguinis.

In considering generally the pathological relations of the anæmiated condition, from whatever cause it may be produced, we must, I think, come to the conclusion that several varieties of this disease have their origin still concealed. I speak here particularly of the anæmia called chlorosis, in which no leucorrhœal discharge, flooding, or hæmatemesis, has been observed, and to account for which I have ventured to express the theoretical opinion that the immediate cause of the degeneration of the blood exists in a loss of exhalant power on the part of the skin. I know it has been the opinion of some authors that amenorrhœa is an occasional cause of this anæmia of chlorosis; a doctrine directly opposed, however, to all that we now know of the physical conditions of the blood, for we may certainly conclude that anæmia, in whatever manner it may be produced, is a cause and not an effect of suppressed uterine discharge. Our state of knowledge as regards the anæmia of the morbus Brightii is somewhat in advance of that which we possess concerning these simple cases of chlorosis, for we have here ascertained a sufficient cause for the production of anæmia in the discharge of albumen by the kidneys; so, in leucorrhœa, menorrhagia, and bloody fluxes generally, we at once can detect an immediate cause for the symptom of anæmia.

In cases of malignant disease there is an appearance produced very analogous to anæmia, but no analyses have been made of the physical and chemical condition of the blood, in such cases, to enable us decidedly to class the condition under this head. There is, however, an analogy between such cases, and those of chlorosis without discharge, in so far that the pallor and pearly whiteness is prominently noticed long before the breaking down and drain of ichorous matter robs the blood of solid constituents.

Anæmia is a symptom of importance in itself, inasmuch as the degenerated blood is capable of producing secondary mischief, and it becomes a matter of absolute necessity that remedial measures should be taken to relieve this condition, when present, while we search for the more remote cause of mischief; for whatever that may be, and in many cases it seems that the blood itself is originally in fault, it is but reasonable to suppose that we increase our chance of effecting a cure if, by our treatment, we first reduce the blood to the healthy standard. It will, I am sure, have occurred to many, to

have benefitted their patients materially by the application of remedies calculated to relieve the anæmiated condition which may have been induced even by a cause which did not itself admit of removal, and thus to have increased comfort and lengthened life. Whether the kidney, the heart, or the existence of any malignant form of disease, be the cause of anæmia, we are almost always able to produce marked benefit by the use of ferruginous medicines, and the exhibition of purgatives; remedies which act beneficially by assisting in the removal of the superfluous water, and in the formation of chyle, such as, from its chemical and mechanical condition, may be able to assist in the production of hæmatosine.

A marked instance of the benefit to be derived by treating this symptom of anæmia, in cases in which the principal evil does not admit of removal, occurred in a patient admitted under Dr. Babington, and lately under my care at Guy's Hospital. The following is a brief sketch of this case.

Robert Curry, æt. 18, was admitted into the hospital on the 18th of December, 1844. He was of delicate frame, and had been sickly from a child. He had before been a patient in the hospital, and was cured of a severe attack of rheumatism and rheumatic pericarditis by Dr. Babington. During this first attack he was bled, and underwent general antiphlogistic treatment. He was relieved but greatly weakened by the attack, and returned to his trade of a butcher before sufficiently recovering his strength. While lifting a heavy weight, he one day experienced a severe pain in the chest, which sensation was immediately succeeded by dyspnoea and palpitation. On his second admission into the hospital his principal complaint was of pain in the precordial region, palpitation, and dyspnoea, with pain in the limbs. He was anæmiated, the pulse was hurried, and tongue white: on auscultation a distinct pericardial rubbing was heard over the sternum: no other indications of disease were present. The treatment of this case consisted first in the application of leeches and use of counter-irritation over the precordial region, with the effect of relieving the pain. He was then immediately ordered the compound steel mixture, and the occasional use of purgatives, with the effect of relieving every symptom of his disease, and reducing his circulation to a regularity such as prevented the occurrence of dyspnoea, and rendered the pericardial rubbing no longer audible. He is now capable of using considerable exertion without distress, notwithstanding that when greatly excited the pericardial rubbing can be heard indicating the existence of the original disease, which, however, no longer produces its distressing symptoms, in conse-

quence of the improved state of the blood brought about by treating the case as anæmia. As bearing upon the principle of treatment, though somewhat unconnected with the immediate object of this lecture, I may mention the benefit which we occasionally derive from the exhibition of tonic remedies in certain cases of neuralgia having their origin in organic lesion which does not itself admit of removal, but the painful effects of which may be counteracted by improving the general tone of the system.

In such cases that which formerly was a cause of disease no longer exists as such; it is paralysed in effect, though present still.

Among the diseases characterised by an excess of water in the system, there is none so pointedly showing the advantage of treating symptoms as that of albuminuria. When this disease is arrived at an advanced stage, it is scarcely to be believed that the removal of the cause would effect a cure, for the secondary effects have attained an importance making their removal a matter of necessity for the preservation of life. Whether the original seat of the mischief be in the blood or in the kidney, we know that disintegration of the former speedily takes place in this disease; that it becomes watery, and contains a smaller proportion of hæmatosine than in health, and did we know the exact nature of the first change from health, and, moreover, were it such as could be expected to yield to remedies, our efforts should be simultaneously directed against the secondary degeneration of the blood, or we can scarcely hope for success. Let us consider the exact condition of a patient suffering from advanced albuminuria, and regard the disease in its relation to the excess of water contained in the blood.

The mischief may commence in the kidneys or the blood, but however that may be, a quantity of serum has passed away with the urine, and impoverished the circulating fluid. Its corpuscles are few in number, and contain a solution of hæmatosine of low specific gravity; genesis is interrupted, and the nutrition of the newly formed corpuscles interfered with, owing to the imperfect manner in which the chyle can make its way through the envelope to the hæmatosine. Serous effusions have occurred, or are about to take place, and the patient is anæmiated. Let us suppose now that the disease is treated for anæmia, and consider what will be the result. Purgatives and ferruginous medicines are administered; the one set of remedies assists to remove water from the blood, the other to supply iron to the chyle. The liquor sanguinis is increased in specific gravity, owing to the removal of water by the aperients, and being in contact with the corpuscles containing a more dilute hæmatosine, an endosmotic

change must immediately take place. The more dilute contents of the corpuscles will be drawn out through their membrane in considerable proportion, and the place supplied by a less quantity of the more dense liquor sanguinis.

This interchange will occur just to such an extent as to equalise the specific gravities of the liquor sanguinis and the contents of the corpuscles, and no more. By the further use of purgatives more water is again removed from the liquor sanguinis, and again the same endosmotic changes will be effected upon the corpuscles. By this use of purgative medicines, the corpuscles have, through the medium of the liquor sanguinis, had the specific gravity of their contents considerably increased, and the chyle entering the circulation, and coming in contact with these bodies, is now able to effect the necessary changes by entering through their membrane, and supplying iron for the formation of healthy hæmotosine.

The ferruginous medicines may be regarded as playing a secondary part in the removal of anæmia when purgatives are administered. Their immediate action is to supply to the chyle that element which is always found in the red contents of the blood corpuscle; but unless a very large quantity of water be removed from this fluid, so as to reduce its specific gravity to the natural standard, and render it far more dense than the chyle, we can scarcely expect that the ferruginous solution will enter through the membrane freely; and, therefore, in these cases, free use of purgatives, more especially of the hydragogue character, seem especially indicated, and it is very common to meet with cases in which iron has failed to exert a beneficial influence until purgative medicines have been persevered in for some time. So marked, indeed, is this peculiarity, that it would lead almost to a belief in an essential difference between such cases, and those which speedily yield to tonic treatment by iron. Regarding the disease, however, as one in which the action of the chyle is interfered with, and being aware of the mechanical conditions necessary to its action on the corpuscles, we can easily understand that it is as reasonable to treat the disease with purgatives as with iron—the one set of remedies inspissating the contents of the corpuscles, and assisting them to endosmose chyle in the manner I have described; the other tending to produce a chyle richer in iron, and which, though it may be able but imperfectly to permeate the membrane of the corpuscles, still supplies a larger quantity of iron in that portion which does enter, than would have been the case had not iron been administered. There are other methods of depriving the blood of water which should not be overlooked in the treatment of

anæmia, the most important of which is that by the skin.

A case of anæmia, which particularly attracted attention, owing to its severe character, occurred to me about three years ago, and was greatly relieved by this treatment—frictions and occasional baths being the means resorted to. In this case, the blood corpuscles, when viewed under the microscope, were observed much distended, a condition prominently shown by those seen on their edges, which were from twice to three times their natural thickness. The sp. gr. of the liquor sanguinis was extremely low, as ascertained under the microscope by the application of solutions. Thus, it required a solution of a sp. gr. as low as 1,007 to effect any considerable endosmotic action, whereas healthy blood becomes so affected by a fluid of 1,029.

I am inclined to believe that the advantage derived from the use of baths consists more in cleansing the skin, and preparing its surface for the excretion of water, than in any benefit that can be produced by the immediate perspirations occasionally observed. It seems probable that water enters the pores more freely than might at first view be imagined, and that it is this superfluous water which passes off in these perspirations. After remaining for some length of time in a cold bath, Chossat found the sp. gr. of his urine scarcely to exceed that of distilled water. This excessive tenuity can scarcely be considered simply as the result of suppressed cutaneous exhalation, and it seems probable that water was absorbed by the cutaneous surface in large quantity. The best method of ridding the blood of excess of water consists in keeping the skin clean by moderate use of baths and frictions, and then enjoining regular exercise as an important part of the treatment. By these means the capillary circulation is accelerated, and blood thrown upon the skin, which is now prepared to excrete water freely for the relief of the blood. The advantage to be derived from free cutaneous transpiration is occasionally to be observed in those chlorotic patients whose mode of life leads them to frequent crowded assemblies, who perhaps take but little exercise except in the vitiated air of the ball-room, and who, to the surprise of their friends, not only escape many of the inconveniences affecting those apparently more fitted to bear such exertions, but, on the contrary, rise on the following morning refreshed and in spirits; a result almost always attributed to the beneficial mental effects of association, but which in many cases I think may fairly be referred to the improvement effected in the blood by free and long continued perspiration. In the case of anæmia, in which I have described the sp. gr. of the liquor sanguinis as being

extremely low, the blood corpuscles were considerably dilated: this is not always the case, because, whatever may be the degree of tenuity of the blood, an adjustment will soon occur between the liquor sanguinis and the contents of the corpuscles, and in many cases of anæmia that I have examined the corpuscles have been pale and flattened. When, however, these bodies are distended, the condition may be regarded as an indication that a fresh portion of water is becoming retained, and is producing effects on the blood at the period of experiment.

In concluding these remarks, I may perhaps be allowed to express a hope that if I have failed to convince, I may yet have suggested matter for reflection which abler and more accomplished minds may hereafter succeed in applying to the advancement of pathology, the treatment of disease, and the relief of the sufferings of our fellow creatures.

APPENDIX TO THE ESSAY

ON

DISEASES OF THE NERVOUS SYSTEM:

CONTAINING NOTES OF THE LECTURES OF
THE LATE PROFESSOR GREGORY,
OF EDINBURGH.

By EDWARD BLACKMORE, M.D. Edinb.

Member Extraordinary of the Royal Medical
Society of Edinburgh, and Physician to
the Bath Penitentiary.

[Continued from page 794.]

On the Cure of Apoplexy.

THE prevention of the disease is most important; attend to the plethora of the head. The regulation of the diet requires attention; it must be a cool and spare diet. Animal food is more nutritious than vegetable; soup, beef-tea, and broths, are a part of animal food; barley or rice in soup promotes the mixture of the fat with the water. This may be allowed to those to whom we do not allow solid food or strong broths. They who are disposed to apoplexy should live principally on vegetable food, such as farinaceous matters—wheat, barley, rice, potatoe, and the roots of vegetables. The patient is not to fill his stomach with a large meal. He may take milk, whey, butter-milk; new milk is very nourishing. In Scotland they allow for the support of a labouring man 160 pounds of oatmeal a week, and milk with it. Cornaro lived to extreme old age on a very spare diet; but he took much wine.

See the case of a miller, who was enormously fat, while using a large quantity of fat meat and ale; he dropped these, and gave up fermented drinks; ate pudding of coarse flour and milk, with eggs,—then without eggs. For years he lived on a pound of biscuit, and a pound and a half of milk, taken at two meals in the day; he enjoyed good health, and was stronger at the age of 50 than at 25.

You must forbid strong liquors of every kind to apoplectic people; all strong spirits are to be given up by them for ever; such drinks, either with water or without it, are most pernicious. Small beer is useful as a laxative in some cases. People ask, "Should they renounce these suddenly, or by degrees?" I think, at once. No one would die for want of strong liquors. Some people are said to have died from a sudden change of diet. I am very sceptical of this. They must also renounce the use of tobacco; it is the most abominable poison ever introduced; even snuffing it up the nose produces vertigo and intoxication; a pinch of snuff impairs the appetite. The smoking of tobacco is more common now than it was forty years ago; it is sometimes enough to bring on palsy (see Burserius, *De Morbis Nervosis*). Some persons tried who could smoke the most; one died at the seventeenth pipe, another at the eighteenth. I knew an instance where it brought on headache for some days. It is a kind of intoxicating drug, and is attended with much danger; some part goes down into the stomach, as happens in chewing it; it must have bad effects. One snuff-taker suffered most grievously with stomach complaints, which I attributed to his taking snuff. Another was seized with vomiting, and threw up a large quantity of snuff.

Moderate exercise is necessary; violent and sudden is dangerous. I recommend general regular exercise; not too long continued; not such as would overheat them. You should not always allow a person predisposed to apoplexy to go on horseback.

Enforce the proper employment of evacuations; keep open the body; insure two motions every day. Try a vegetable diet for this purpose,—stewed prunes, pears, and apples; barley-broth also is laxative; milk, particularly when boiled, is binding. Give a purge

occasionally, as sulphate of magnesia, colocynth, and the compound powder of jalap. Use aloe and rhubarb on going to bed, or jalap and calomel. Active saline purges are also sometimes required, as sulphas sodæ, tartaras potassæ et sodæ, sulphas potassæ; they lessen the flow of blood to the head so much, that the face will look pale; people even fall into syncope from their operation, which is the reverse of what produces palsy and apoplexy. People will take mineral waters, even the Harrowgate, who will not take medicines. It is the purge that makes that water valuable; the sulphur in it is nothing. The change of air also, which people get in going to watering-places, is useful.

An issue or blister about the head or neck is good. I recommend it if the other means are inefficacious; but the evacuation is so small, that it is not so useful as purging.

Blood is to be drawn. I bleed to twenty ounces, if the threatening symptoms are urgent; if they are less severe, I employ topical bleeding by leeches on the head; but this evacuation being slow, the effect is not so great. Cucurbitulæ cruentæ are better than leeches. I recommend in some cases opening the temporal artery; if the blood does not flow, you should apply cupping-glasses.

The excretions are lessened by bleeding, for it relaxes the vessels. Bleeding from the head, some say, increases the habit of determination of blood to it; but if the threatening of the disease is urgent, you try both local and general bleeding.

The cure in the attack.—On the attack coming on, you must use powerful remedies. Maintain the erect posture; people are to be propped up in bed. People faint on sitting up while blood is drawn, from the flow of blood to the brain being lessened; on lying down they recover. Weak people faint in the erect posture. Keep the patient in pure cool air; it is hurtful to the brain and to the lungs to breathe impure air; so the keeping the patient's own heat about him by a load of bed-clothes, and the accumulation of the perspirable matter, is bad. Tight ligatures about the neck are bad; the face will swell and look blue from them; therefore take off the neckcloth, and open the shirt collar.

A large bleeding is to be employed from the arm or jugular vein. Some physicians object to bleeding. Dr. Fothergill says, "Bleeding requires dispassionate consideration; hemiplegia or death may follow it. If the pulse is full and tense, with an appearance of suffusion in the countenance, even then bleeding is performed much oftener than is proper. The pulse is an insufficient guide for bleeding: consider the habit of body before you bleed; if purging do not relieve, bleeding will sap the strength; and for the most part it is injurious." Now, however this may apply to people in London, we bleed here without ceremony: if the patients die after it, the attendants may think death was from the bleeding; but if they be not bled, they will die in a few hours. In the case of a little thin man, who was very pale, so that you would hardly conceive he was in a plethoric state, I ordered spare diet, maintaining an open body and gentle exercise; he was relieved for a time, and then he fell early in the forenoon into a fit, with complete coma; he was bled largely, and while the blood was flowing he awakened. In a few hours, however, he was again attacked, and died. Dr. Fothergill has cases in which he thought bleeding did harm. It is strange that what is proper before the fit comes on, should be improper after it has come on. The flow of blood to the head will continue except you bleed. I have often seen the immediate good effects of bleeding. There will be no end of controversies with respect to the practice of physic. I believe apoplexy often so far resembles inflammation, as to favour the idea of its being from an hæmorrhagic action of the blood-vessels, and it is named by Hoffman hæmorrhagia cerebri. We bleed to twenty ounces, or repeat moderate bleedings. Blood has been drawn to eighty ounces in a short time, with a good effect. There is no reason to prefer bleeding from the jugular vein rather than from the arm. It was an old practice to bleed from the ranular veins under the tongue. Open the anterior branch of the temporal artery; apply cupping-glasses, or leeches not less than a dozen. The good of topical bleeding is from the effect of the sympathy of the external and internal parts, and not from the quantity of blood drawn. Sometimes

it is proper to reduce the pulse by cold, purging, and low diet, and not by bleeding. The head is to be shaved, and cold applied by washing it with water and vinegar; after this, you might apply a large blister on the crown of the head.

Purging is the next powerful remedy to bleeding. Give two drachms of sulphate of magnesia every hour, and the decoction of senna, which is better than the infusion; give also ten or twenty grains of jalap in honey or treacle, with calomel, or give ten grains of calomel without the jalap. I do not like the larger doses of calomel; I should not use it indiscriminately. A purge has a great effect on the head: but there may be such torpor of the bowels as to render purgatives inefficacious. Clysters are good; the enema terebinthina was formerly much used; clysters of water, or decoction of senna, with an ounce of sulphate of soda, are proper. The effect is instantaneous.

Emetics are recommended, under the idea that a full meal is the common cause of apoplexy; an undigested meal, they say, pressing on the aorta, forces the blood to the head. A full meal is not the most common cause of the disease. I know of many cases which occurred early in the morning, and just before dinner as well as after it; yet rich high-seasoned food is a powerful stimulus, and will throw more blood to the head. If the danger is from a flow of blood to the head, an emetic would be dangerous, for vomiting increases the surcharge of blood in the head. In fever patients, an emetic in a full habit of body has been fatal; they have become delirious and comatose. Yet tartarized antimony may be useful in apoplexy, the vomiting from it being less dangerous than the state it is to remove. If people require bleeding and an emetic, the former should go first. The sulphate of zinc operates quickly, and is safer for removing undigested food than the antimony.

Sinapisms to the feet may be useful; but they are not to be trusted to.

In serous apoplexy, which occurs in people who are not plethoric, but who show a tendency to dropsy and a depraved habit of body, in whom a watery effusion in the brain takes place independent of active determination of blood to the head, it would be absurd

to employ remedies as in the sanguineous disorder. I believe that these varieties are essentially distinct, and that the treatment should be different; some cases, however, of this species are relieved by a moderate bleeding, but I don't often think of employing it in dropsical people who become comatose; they are relieved by blisters to the head and neck, and by purging. Drastic purges are useful, even in unpromising cases. The coma has gone off while the purging has been going on.

The Treatment of Palsy.

People seldom die of the first fit of hemiplegia, when the inflammatory state has been removed. Sometimes the attack is very transient, and hence lavender drops get the credit of the recovery. You should not always attribute to a medicine the favourable changes that appear. All stimulants, general or local, as volatile alkali to the nostrils, in this variety of palsy, injures the brain; yet people will revive attempts at old-fashioned practice. Recovery may be very slow. May the bad effects of pressure on the brain remain after the pressure is removed? I believe they may; people live for years after hemiplegia, without recovering fully. Make pressure on the nerve of your leg; remove the pressure, yet the numbness will continue for some time. If you were to bruise your sciatic nerve, you would not recover the use of the limb; so, when a part of the brain is injured by pressure, this may be removed and yet the palsy will remain.

Stimulants, external and internal, have been used. I have little faith in them; they have been supposed to do good, when the real benefit was from nature and time. People have recovered just as well without them, and they have used them without the least benefit. Stimuli are little to be relied on in hemiplegic palsy; in the palsy of the legs from cold, and in partial palsy from the mineral poisons, they have been useful.

External stimulants are safer than internal, and there is a greater chance of success from them. Sulphuric acid with oil has been applied to the skin; it is, in my opinion, useless. Ammonia is a better stimulus, mixed with eight

parts of oil, as you don't want to produce permanent inflammation on the skin. Ammonia applied to the nostrils is dangerous. Sea salt is also used, so is brine; as a rubefacient it is of inferior efficacy to the linimentum ammoniæ. Volatile oils are powerful stimulants; as oleum succini, petroleum, terebinthina. I use mustard most commonly; sinapisms induce inflammation, which may run into gangrene; you must look well to the limb after applying it. Sinapisms will induce inflammation in one hour; in general they are safe; a blister is, however, preferable. Stinging with nettles also is used for palsy of the limbs. Friction with a flesh-brush, or a rough flannel cloth, or a horse-hair cloth, is a powerful stimulus to the nerves and blood-vessels of the skin, and it promotes the circulation. Some physicians impregnate the flannel with aromatic steams, or dusts, as those of styrax and benzoin: patients then think more of them: the friction is the most powerful part of the remedy. Heat is, in general, the most powerful of all stimulants; by it life is supported. Warm bathing is used, and the hot mineral waters, as the Bath waters. A safe way of applying it is the warm pumping.

Cold is a stimulant sometimes; you see this in dashing cold water over people to rouse them from syncope. The cold bath is used in the cure of palsy, supposing it is a tonic. It is stimulant only from intense cold made by a shock; cold permanently applied is a sedative, and would benumb the parts; a transient sudden application of it is followed by an increase of heat all over the surface, from the increased action of the heart and arteries. The plunge bath is rather an ambiguous remedy; and cold applied to the extremities may drive the blood to the head, and bring on a new attack of palsy: I don't like to prescribe this bath. The shower bath is safer, and more likely to be effectual; but the feet and legs may be chilled by the cold water.

Electricity is a powerful remedy in the palsy of water-gilders from quicksilver; and it is applied to the cure of palsies of every kind. I doubt if any one in palsy, not from mineral poisons, was ever cured by that stimulant. I have known it tried in many cases,

carefully, for a long time; not one derived benefit from it. The sparks are safe; I have had hundreds taken from the extremities, without the risk of inducing fresh attacks; the shocks are not so safe. The difference in these two modes is only in degree.

Exercise, so as not to produce fatigue, is a very excellent remedy; strength will be gained by it, but it must not be violent.

Some recommend the fumes of burning alcohol to be directed to the palsied limb; don't trust to it.

Internal stimuli are of less use, and more dangerous, than the same substances used externally. Some give ten grains of carbonate of ammonia; others give mustard or horse-radish. The patient may use it for a condiment; but I doubt if the stimulant in the stomach has a direct effect on the palsy. Infusum raphani is diuretic, and may stimulate the absorbents in the brain to carry off the effused serum. Aromatics are used, as pepper, and the essential oils; their stimulus is too great, too permanent; that of carbonate of ammonia is sooner over. Some give alcohol, as in the compound tincture of cardamoms, and the aromatic spirit of ammonia. I disapprove of it; it cannot do any good; and any approach to that poisonous article alcohol is improper.

The Germans recommend many things of this sort; they are too credulous regarding the virtues of medicines.

Some practitioners give guaiacum, ten grains in a bolus; or in a mixture, in which form I avoid it. Some use the tincture, in water or milk; it sticks about the teeth. I don't use it much; I don't rely on it. It is given to produce sweat; it does so; but sweating may not be good in palsy.

As to tonic medicines, they are perfectly insignificant; yet I prescribe them to gratify patients. A patient might suffer from an improper use of guaiacum; yet a small quantity of bitters, or iron, as thirty drops of the ammoniated tincture, may be taken—if they please; or the precipitated carbonate of iron, which I use. The oxide is here brought into an impalpable powder, by precipitating it from the solution of sulphate of iron with carbonate of soda. It is very safe, and is a tonic if any medicine gives

strength; yet I believe there is not a decisively tonic power in any medicine whatever.

Antispasmodics, as assafoetida, have been used in palsy, as also in hysterical cases, on the idea that the rolling of a ball in the belly was from the womb, and that the uterus liked good smells, and disliked bad smells: hence the old physicians tried aromatics to the pudendum; and such was the origin of the use of antispasmodics and foetids. Valerian has been used as a *placebo*; people are satisfied if they are using something.

Emotion of the mind may do good in some palsies; just as it will stop a spasmodic affection.

[To be continued.]

POISONING BY HYDROCYANIC ACID.

To the Editor of the Medical Gazette.

SIR,

IF you think the following memoranda of a case of poisoning by hydrocyanic acid worth a place in your journal, you will, by inserting them, oblige

Your obedient servant,

CHARLES POOLEY.

Cirencester, March 21, 1845.

On the evening of the 23d of January, I was summoned to the aid of Mr. H., a medical gentleman of Stratton, near Cirencester, who was reported to have poisoned himself. I found him lying on his back on the hearth-rug, his head supported by a folded shawl. His countenance was placid and free from all contortions, his eyes closed, and the pupils not largely dilated; a fresh healthy colour was on his cheeks. His limbs were quite supple, and his body warm. Life had been extinct about ten minutes. From the statement made to me in the room, and which afterwards appeared in evidence at the inquest, I learnt that he had returned home from a long round of visiting, much fatigued, and feeling a pain in his chest, took the bottle of acid from its place in the surgery, and went into the parlour adjoining for the purpose of taking a minim dose to relieve it—a remedy he had more than once had recourse to before, for the same purpose. While there he was heard to stagger, and as the housekeeper rushed into the room, he fell, and an ounce-

phial, about half full of hydrocyanic acid, of Scheele's strength, corked, dropped from his hand. She rang the bell violently, and gave the alarm, and in five minutes his brother, who is a medical man, was on the spot. He was then breathing, and his pulse was distinctly perceptible at the wrist. Notwithstanding every means was tried to counteract the effects of the poison, he expired in a few minutes without any scream, and quite tranquilly.

An inquest was held on the body, and I was directed to make a post-mortem examination.

Appearances twenty-two hours after death.—Weather very cold. The body was cold and rigid. All the depending parts, as the back, shoulders, bend of elbows, &c. were of a mottled purplish colour. On opening the chest the right lung presented a dark dusky purple appearance, was not much collapsed, and contained air. On being cut into, a frothy dirty-brown semimucous fluid exuded, tinged with blood. There was no odour of prussic acid from it. In the cavity of the right pleura were about eight ounces of thin serum; the surface of the pleura was not marked by any evidence of inflammation. The left lung was of a pale colour, quite exsanguine, contained but little air, and poured out only a whitish frothy mucus on being cut into; it was firmly adherent in its whole extent to the costal pleura of the same side, and posteriorly the adhesions were so strong as to defy my strength to separate them. The pericardium was natural; it contained perhaps a little more fluid than usual in its cavity. The heart was small, and firmly contracted, and the vessels on its surface distended with fluid blood. On cutting into it about three ounces of dark coloured fluid blood trickled out, without the least appearance of coagulation having been attempted. It exhaled no smell of prussic acid. The parietes of the ventricles were a little thicker than usual. The liver was large and healthy. The spleen soft and easily broken down, resembling mulberry jam. The kidneys were firm, rather large, and slightly coagulated. The stomach contained about fifteen ounces of half-digested food, that gave out the peculiar smell of food undergoing digestion, with which also could be satisfactorily recognised the well-known

odour of bitter almonds. The mucous coat of the stomach was healthy, and smelt strongly of prussic acid after the stomach had been emptied of its contents. The intestines were healthy. The brain and its coverings were healthy, but its vessels and its sinuses were filled with dark-coloured fluid blood. It was quite free from any smell of prussic acid.

In this case, 1st, he had power to cork the bottle after having taken the poison; indicating its paralyzing effects on the sensorium not to have been instantaneous. 2nd. The placid state of his features, unmarked by any act of expiring. 3d. There was no scream, but he died tranquilly and silently. 4th. The congested state of the right lung might more reasonably be referred to the effects of chronic pneumonia than to the poison. 5th. The blood was everywhere dark coloured and fluid. 6th. The odour of bitter almonds was satisfactorily recognised in the stomach, and no where else. 7th. He lived nearly ten minutes after having taken the poison.

ANALYSES AND NOTICES OF BOOKS.

“L'auteur se tue à allonger ce que le lecteur se tue à abréger.”—D'ALEMBERT.

Remarks and Comments on the Medical and Chemical Evidence adduced at the trial of John Tawell. By G. L. STRAUSS. London, 1845. 8vo. pp.23.

WE are induced to notice this pamphlet solely on the ground that the subject of which it treats has lately excited the greatest interest in the minds of the public and profession. We have most carefully read it, and we rise from the perusal with a feeling of astonishment. It might have been, we think, more aptly designated, “An attempt at a scientific justification of murder by prussic acid.” We have in our recollection an old saying, “use soft words and hard arguments;” but the writer of this pamphlet has exactly reversed the proverb, for harder words and softer arguments on so serious a subject, affecting as it does the administration of criminal justice in respect to the most detestable crime of which man can be guilty, “murder by secret poisoning,” it has, we believe, never been our lot to encounter. The key to

the whole of the reasoning, if it can be so termed, we find in the author's conclusion:—John Tawell is an innocent man, and his execution will amount to judicial murder*. Now setting apart those who were present at this trial, and entirely excluding the legal and medical counsel employed in the defence, we do not believe that there are five unprejudiced men in the empire, capable of forming a judgment on such a subject, who share these sentiments with Mr. Strauss. This belief would at once justify us in taking no notice of a pamphlet, consisting as it does of the most unfounded abuse of all the medical witnesses engaged for the prosecution, as well as of the learned and excellent judge who tried the case, but for the interest of the subject, and its important bearing on all future cases of death from this poison.

Every man who has dabbled in poisons, even to the slightest extent, believes himself at once to be a “*médecin expert*,” and qualified to pass judgment on those, whose only object by acting as witnesses is to aid the course of justice. There never was a trial for murder by poison, involving a great and atrocious crime, followed by a righteous conviction, in which some person did not appear to object to the evidence. This has been more especially the case, when the criminal, by rank, or fortune, or talent, has excited more than usual notice:—or when his crime has been marked by more than the usual amount of the cunning and forethought indicative of the secret assassin:—he always finds his defender, and becomes *pro tempore* a martyr to the deceived laws of his country! From the trial of Captain Donellan, in England, about sixty years ago, to the more recent criminal “drama” of the “*affaire Lafarge* in France,” this remark will be found to hold good; and it would indeed have been surprising, had the case of Tawell formed an exception.

Mr. Strauss takes up the position that the woman Hart did not die from prussic acid, but from some unascertained cause of sudden death. He comes to this conclusion, too, on the evidence adduced, which we shall now proceed therefore to examine. In the first

* The greater part of this notice was written before the execution of Tawell, and before it was known that he had made any confession.

place, we entirely object to the author's introducing into his pamphlet any matters detailed at the coroner's inquest. The jury (a different jury to that at the inquest) returned their verdict against the prisoner from the evidence given in the assize court at Aylesbury. Both the counsel for the prosecution and defence specially impressed this on their minds; therefore what passed at the preceding coroner's inquest, is perfectly irrelevant. The author thinks that he can detect some serious discrepancies in the evidence of the Crown witnesses on the two occasions; but this appears to us to be trivial, and not to bear upon any important point in favour of Tawell. We are inclined to put more confidence in the legal acumen of the counsel for the defence, than we are in the medico-legal opinions of Mr. Strauss; and we are quite certain, that had there been any discrepancies material to the case of the prisoner, they would not have escaped observation and an eloquent exposure from Mr. Kelly.

The first tangible objection, with which we meet, is that only "a minute amount of prussic acid was obtained from the contents of the stomach." 1. At page 14, the author admits this to have been "about *one grain*," although he considers it absurd to infer therefrom that the deceased died from the effects of this poison. We should like to know what precise quantity of any poison the author would require to have discovered in the stomach, in order to admit the supposition of death having been caused by it. It would appear from this statement, and from his subsequent argument respecting the dose required to destroy life, that it is indispensably necessary to discover a certain quantity of prussic acid in this organ, or poisoning is not proved. The author is here adopting one of the arguments, fallacious as it appears to us, which was used by the learned counsel for the defence. Such an argument may come well from a lawyer in the excitement of the occasion, and who, "*ruat calum*," is bound to make the best of a case for a prisoner, even by the use of what to all professional men must appear the most inconclusive reasoning;—but we opine that it comes very ill, in the deliberate exercise of the pen, from a man who evidently has given some attention to these subjects,

and who certainly cannot plead the same professional excuse.

Let us put the question plainly. Is it necessary in any case of poisoning that a *certain quantity of poison by weight or measure* must be found in the stomach of a deceased person in order to prove that this has been the cause of death? If Mr. Strauss be consistent to his argument, he would answer in the affirmative; although he has not told us what is the precise quantity required, to establish innocence on the one hand or guilt on the other; for such would be the issue of the question on all criminal trials. It is notorious that persons have died repeatedly from arsenic, oil of vitriol, oxalic acid, and opium, without a single particle of either of these poisons being detected in the stomachs. It has been passed away by vomiting or purging, become absorbed or decomposed:—but, nevertheless, knowing that there are easily understood means by which poisons may be lost—not to mention that the fatal dose may have been originally small—no difficulty has hitherto been experienced, by persons who have certainly seen more of these cases than the author, in determining that poison was really the cause of death. As we understand the reasoning put forth, he would give impunity to all cases of murder by poison, unless sufficient to cause death were actually found in the stomach: *i. e.* if the quantity found were so minute as he alleges it to have been in Tawell's case, he would, so far as concerns prussic acid, account for its presence in the stomach in some other manner, and thus do away with the hypothesis of its having caused death. Now supposing a person to swallow only just a fatal dose, say about twenty drops of Scheele's prussic acid: unless the whole of this quantity were found in the stomach (this would be about equal to one grain of anhydrous acid) Mr. Strauss would object to the chemical evidence of poisoning as inconclusive. The bringing home guilt to a prisoner he would therefore make to rest in all cases of poisoning upon the inaction of the stomach and bowels during the time the person lives after taking the poison, upon its non-absorption and non-evaporation, but, above all, upon the accidental amount of the dose administered! All crafty assassins, who give only enough to de-

stroy life, would thus escape if the author had to try them, while the bungling murderer only who administered ten times as much as was required to destroy his victim, would be convicted! We shall see presently that the author places great reliance upon Orfila: let him take a lesson from what that learned toxicologist states in reference to arsenic,—the rule applying, we believe, equally to all poisons. That portion of the poison which is found in the stomach after death is the *surplus* of that which has destroyed life: so that all tests applied to the contents of the stomach act upon the residuary portion found in this organ. That which has really caused death has been carried away by absorption into the system during life.*

The learned judge who tried Tawell, and whose summing up this writer designates "*very impartial*," (sic) has given an answer, marked by sound sense, to the absurd doctrine which we have been endeavouring to expose. He told the jury that "it was not necessary to prove what quantity of prussic acid would destroy life, by the testimony of a person who had actually seen a human life destroyed by it: neither was it necessary to prove that such a quantity as would destroy life had been found in the stomach." If this were not the law, hundreds of murderers would assuredly escape conviction, and we should have numerous treatises on "Poisoning made easy," showing by accurate calculations how much and in what vehicle any particular poison might be given without incurring the penal consequences of the (Mr. Strauss's) law.

But the author goes even farther, and denies that the detection of prussic acid is any proof of poisoning at all. In support of this view he quotes Orfila's opinion, but without adducing a single fact to support his reasoning. He here proves too much; for his reasoning goes the length of showing that criminal prosecutions for poisoning by prussic acid should be at once abandoned; because "prussic acid is formed in some cases (if it applied in Tawell's case

it would certainly apply in any) in the animal organism, even although the individuals offering the phenomenon be in a state of perfect health." p. 15. Why should not the legislature, then, at once give up poisoning by prussic acid as such a very doubtful matter of proof that no person could henceforth be safely prosecuted on the charge of criminally administering it? Because, 1, it may be formed, "in some cases," in the body, and 2, because persons who are killed by prussic acid die very much like those who are cut off by apoplexy, epilepsy, or any sudden cause of death! Let it be in future, therefore, free warren for murderers!

Seriously, however, we must look to the author's facts more than his own and Orfila's sayings in support of this opinion; but we have been unable to find that he ever detected prussic acid either by the odour, or by any chemical test in the contents of the stomach of any person whose body was examined eighteen hours after death, and who certainly could not have died from swallowing prussic acid. Not a single instance of the kind do we find recorded as observed by himself or others. There has been sufficient time for Mr. Strauss to have visited dead-houses, and to have extracted prussic acid from the contents of the stomachs of the recently dead. A discovery of this kind, which his language would lead us to suppose as likely to be made with very little trouble, would have done far more service to Tawell than speculative suggestions on the possibility of its production from the decomposition of animal matter in a case in which no sign of putrefaction existed (see MEDICAL GAZETTE, p. 519), or bitter invectives against the judge and the medical witnesses. Let the following be taken as a specimen of the way in which he attempts to support his opinion scientifically, the reader bearing in mind that the reasoning (?) applies to the contents of a deceased person's stomach carefully examined only eighteen hours after death by competent persons, who could not find in it either "bitter almonds, pomaceous seeds," or "ferrocyanide of potassium," all substances not likely to escape observation.

"It is a well-known fact (?) that the perspiration of some perfectly healthy individuals exhales the peculiar odour

* So little is the law disposed to act upon Mr. Strauss's views, that a case is recorded in which a prisoner was convicted of poisoning, although the quantity of arsenic found in the stomach was only the one-fortieth part of a grain. See Edinburgh Medical and Surgical Journal, Vol. 29, p. 23.

of hydrocyanic acid; and sulphocyanide of potassium has been detected in the saliva by Tiedemann and Gmelin. Moreover, it would be very absurd indeed to deny that prussic acid may be formed in the decomposition and putrefaction of organic matter, just as likely as ammonia, acetic acid, and other similar compounds, to the formation of which the simple decomposition of organic matter gives rise. Bitter almonds, and pomaceous seeds, may be (?) present in the stomach, and subsequently, upon the distillation of its contents, yield hydrocyanic acid. Ferrocyanide of potassium is a perfectly innocuous substance: this may by chance have been partaken of (!); (as is frequently the case in manufactures of ferrocyanide of potassium—vide Liebig's lectures on Organic Chemistry in the *Lancet*), and would of course upon distillation yield a considerable amount of prussic acid." p. 15.

We were certainly not aware of the "well-known fact" referred to, of the presence of an odour of hydrocyanic acid in the perspiration of some healthy individuals; and, admitting the truth of the statement, we cannot rest satisfied with a mere odour in the perspiration of a healthy living person, as an analogous explanation of the production of liquid prussic acid in the contents of the stomach of a dead female; for we presume the author does not mean to say that the prussic acid was exhaled from the mucous membrane during life; and, if after death, he must establish the possibility of this by something like an analogical condition. If it could thus have been possibly produced by putrefaction within eighteen hours after death, should it not have been indicated by an odour? and yet on this point he strenuously argues that there was no odour, and that the witnesses who swore they perceived it (Mr. Champneys and Mr. Pickering) were mistaken. We think it very unlikely that prussic acid should be formed during the putrefaction of the contents of the stomach as readily as ammonia, or the question of its spontaneous production would not now be a matter of dispute among chemists: and Mr. Strauss would be enabled to furnish us with some facts in proof of it, instead of mere speculation. He might contend with greater justice

that when oxalic acid is found in the stomach of a person suspected to have died from that poison, it had been formed from a reaction of the elements of animal matter. Oxalic acid is actually found (as oxalate of lime calculus) occasionally in the cavity of the bladder, and why may it not be produced in the stomach? Prussic acid has never been found as the result of such reaction in the bladder or any other mucous cavity of a recently dead body; and therefore we hold that the argument is more strongly in favour of the spontaneous production of oxalic than of prussic acid. If the Crown witnesses in Tawell's case had only trusted to the *odour* of the contents of the stomach, as evidence of poisoning by prussic acid—*i. e.* if they had entirely failed in separating any portion chemically—no one would have been more indignant at their rashness than the author of this brochure; although here we find him arguing against the validity of chemical evidence, where the poison is actually separated in a liquid form, because the perspiration of some healthy individuals exhales the *odour* merely of hydrocyanic acid. If Mr. Strauss had extracted the prussic acid from the perspiration under the form of Prussian blue, or cyanide of silver, there might have been some excuse for his reasoning, and some hope of inducing chemists to believe that prussic acid is really exhaled by healthy living persons; but until these necessary proofs are adduced we shall be just as inclined to admit that healthy human beings occasionally exhale morphia, strychnia, or aconitine.

Thesulphocyanide of potassium exists in traces in the saliva, but not, so far as we know, in the mucous secretions of the stomach; and if it did, even in much larger quantity than in the saliva, we do not believe chemically that prussic acid could have been extracted from it by the process adopted by Mr. Cooper. We must give credit to the author for his silence on the "pomaceous," or "apple-pip" hypothesis. It is said that the learned counsel for the Crown was advised by chemists in the defence; but it appears to us quite inexplicable how such a view could have been taken, when Mr. Cooper, in his cross-examination, expressly told the learned counsel that in examining the contents

of the stomach "he did not observe with the apple *any pips either partially masticated or otherwise*"—this question, too, being preceded by an exact statement of what was found in that organ. So far as the chemistry of the matter was concerned, it would have been just as probable to have assumed at once that the carbon, nitrogen, and hydrogen of the apple had resolved themselves into prussic acid, as to argue that it resulted from the distillation of substances not found to be present on a careful examination of the contents, and which ought to have been present in very large proportion in order to have given any plausibility to this line of defence.

Mr. Strauss is exceedingly indignant that Mr. Cooper should have been allowed to act as a witness, he being merely an "analytical" chemist. He is also severe on Messrs. Champneys, Norblad, and Pickering, who, although regular medical practitioners, are, he considers, men of no experience. Without arguing this point with him, he might have dealt out justice to all the witnesses; but we observe that he is silent respecting a Mr. Thomas, "*a shopman to a chemist*," who, because he sold prussic acid to the prisoner in the way of business, was allowed to give a very positive opinion on a question which we do not hesitate to say would have puzzled an Orfila or a Christison; namely, How many apples were required to furnish pips sufficient to produce two grains and a quarter of cyanide of silver? And it would appear, from Mr. Thomas's experiments, that fifteen small apples are required for this purpose*. This witness was also allowed to give an opinion upon what would, and what would not, conceal the odour of prussic acid! Then, it appears, he poisoned a parrot with thirty drops of Scheele's acid, and created thereby such a powerful smell that three women were obliged to run out of the room, the scent (*i. e.* from thirty drops of Scheele's acid injected into the throat of a parrot) was so strong and suffocating. Further, he is

reported to have said that "the bird was afterwards stuffed!" Let any of our readers consider whether this was not a far stronger case to complain of the indiscriminate admission of persons as witnesses on important scientific questions, than in respect to the other Crown witnesses. But the explanation of this is, that this witness's evidence was favourable to the prisoner.

One other medical question Mr. Strauss presumes to discuss, and with an equal disregard of scientific reasoning; this is, the dose required to destroy life. He copies his facts from the defence; for we think we shall be able to show that he has very imperfectly informed himself of the exact particulars of the cases upon which he bases his arguments. Mr. Cooper obtained from the stomach a quantity of prussic acid equal to twenty grains of Scheele, or fifty grains of the London Pharmacopœial acid. The question seems to have been raised (although why, it is difficult to perceive) whether this quantity was sufficient to kill the deceased; and it was contended that it was not—a view supported by Mr. Strauss, so far as we understand his arguments. The deceased, if she swallowed any of the poison, must have swallowed more than was found in the stomach, unless we suppose that the processes of absorption and evaporation were specially suspended in her case. The author censures the Crown witnesses for stating that less than a grain of anhydrous acid would destroy life, and triumphantly confutes this view, as he supposes, by referring to himself, he having, as he says, swallowed 2.1 grains of anhydrous prussic acid, *largely* (?) diluted with water, without feeling any very considerable inconvenience! The quantity thus stated to have been swallowed without injury by Mr. Strauss is equivalent to *forty-two grains* of Scheele, or rather more than *one hundred grains* of the London Pharmacopœial acid! This is corroborated by a statement that a cat can bear without inconvenience from two to three drops of anhydrous acid, diluted with from four to six ounces of water; or even two drops of pure anhydrous acid placed on its tongue, if the animal can be induced to hold its breath. But what does all this amount to? If the author had once swallowed an ounce of Scheele's acid with im-

* We believe Mr. Cooper to have been quite correct when he said that the quantity of prussic acid which he obtained from the pips of about fifteen apples was quite inappreciable. We are not even certain that the witness, Mr. Thomas, could distinguish cyanide from other compounds of silver, and certainly, from his status, should decline receiving his opinion on the point.

punity it would certainly be a very remarkable fact in toxicology, and show a constitution impregnable to poisons which even Mithridates himself might have envied; still, it would not prove that others of the Queen's lieges could swallow with equal impunity thirty drops of Scheele's acid; and we believe it to be certain that, at the strength of five per cent., ninety-nine out of a hundred persons would assuredly die from this dose. The deceased woman, Hart, probably possessed only an average constitution; she did not swallow the poison in a gallon of porter, nor did she place it on her tongue and hold her breath! It is impossible to conceive what can have been the author's motive in bringing forward such inapplicable illustrations of the alleged harmlessness of what most persons regard with propriety as a poisonous dose of prussic acid*. A few cases are reported where persons have recovered from ounce-doses of tincture of opium; but a person has certainly died from a dose of two fluid drachms. To adopt Mr. Strauss's reasoning, if a man has once been able to bear a large dose of a poison, it is not probable that a smaller dose will kill another man, although given under very different circumstances. This reasoning, we think, cannot be improved!

The author goes on to say, in spite of the very absurd conclusion to which his argument necessarily tends, that "a most egregious blunder" has been committed in English works by their authors stating that in the cases of the seven Parisian epileptics, each was killed by so small a dose as seven-tenths of one grain of the anhydrous acid. Dr. Christison states that the dose was two-thirds of a grain; Mr. Taylor, seven-tenths of a grain. The most curious part of this history, and a very singular test of the author's accurate research, is, that the cases referred to are reported by Orfila, with a full account of the inspection of the body of one subject, in the *Annales d'Hygiène*

for 1829 (p. 507), when Mr. Strauss says the lamentable event took place "only in the year 1830!" p. 19. Perhaps it will be better to trust Orfila in his original report, than Mr. Strauss in his quotation; for although the latter quotes Orfila, he has evidently only looked at the last edition of his *Toxicology*, in which it is stated to have occurred in 1830. Orfila says (*loc. cit.*), "Mais ce qui achève de nous convaincre, c'est le récit de sept ouvertures de cadavres d'individus ayant tous succombé dans l'espace d'un demi-heure à trois quarts d'heure pour avoir pris chacun environ vingt grains d'acide hydrocyanique médicamenteux." Dr. Christison and Mr. Taylor have evidently regarded this as Vauquelin's acid, *i. e.* at 3.3 per cent., which would make the dose nearly what they represent it, were the French grains equal to the English; but as the weights are not equal, the dose would be actually less. Orfila does not state to what medicinal acid he refers, and after dealing in "ifs" on this very material point, Mr. Strauss goes on to say: "Thus, for seven-tenths of one grain of prussic acid, which we find reported in the English books on this subject, we must substitute at the least two grains and one-fourth (*i. e.* of anhydrous acid). Had Mr. Baron Parke known this fact, he would probably have abstained from stating, in his summing up, that a larger amount of prussic acid had been found in the stomach of the deceased than would be quite sufficient to destroy life." (p. 20). That two English writers should differ from each other respecting the dose to the amount of only one-twenty-fifth part of a grain, is not very surprising, when the French authorities differ among themselves, and leave the matter so unsettled. We believe, however, that Vauquelin's acid was here intended by Orfila, when he spoke of medicinal prussic acid. In connexion with this case, the author again raises up the "odour" of prussic acid. Although Adelon, Mare, and Marjolin, could perceive no smell, yet Gay Lussac and Orfila could perceive it (p. 20) eight days after death. Orfila states this in the last edition of his *Toxicology*, published *fourteen years* after his first report of the case, in which he says nothing whatever about the perception of any odour. On the contrary, in a

* The opinion of many toxicologists that thirty drops of Scheele's acid are certainly sufficient to kill an adult, has been fatally confirmed since Tawell's trial by the following case, communicated by a friend. A mixture containing two drachms of Scheele's acid was given by mistake to a young woman. She was ordered to take one-fourth part for a dose. She died in ten minutes after the first dose, containing thirty drops of Scheele. The case occurs at the very time to show the absurdity of the defence on this point.

very full account of the post-mortem examination (*Annales d'Hygiène*, 1829, p. 509) of one of the seven patients he expressly says, "Après avoir fait les ligatures convenables pour recueillir les matières contenues dans le canal digestif, ce canal est enlevé : on place dans un vase tout ce que renferme l'estomac, et on procède à l'examen de celui-ci : nulle odeur particulière ne s'en exhale." Again, subsequently : "Nulle partie n'exhalait l'odeur d'amandes amères." What greater confirmation of the correctness of Dr. Christison's statement could be needed?—and yet such absurd stress was laid upon this, as a most serious error at the trial. Dr. Christison says that there was no odour in the stomachs of these patients, when it is alleged to have been perceived by two persons out of five! The fact is, it seems to have been forgotten both by Mr. Strauss and those who conducted Tawell's defence, that the seven patients had *seren* stomachs; and so far from finding it stated that the odour was perceived in all, the earliest report of one case shows that in that instance, taking Orfila's own words, there was no odour whatever of the poison perceptible to himself. It is worthy of remark that Mr. Strauss makes the loss of odour here a still more remarkable fact, by saying that the dose of anhydrous acid was $2\frac{1}{2}$ grains, instead of 7-10ths of a grain!

We have very little to say upon the author's objections to the evidence from an inspection of the body. There are some pathological alterations which he says he should invariably expect to find in all cases where the person has lived a few minutes after taking the poison; but what they are he omits to state, although it is a great desideratum in toxicology that there should be some certain and indisputable evidence from this source. He says, the bile is, "*in most cases*," of a blue colour; whereas two cases only are known, on the authority of Christison and Taylor, in which this has been observed. These occurred to Merzdorff, (*Horns' Archiv*, 1823, 2, 51), who expressly states that these were the only two he ever met with in which the bile presented this colour. He then enumerates some common morbid conditions of the body which are found in cases of sudden death from other causes; and after this summary of a series of negative or

equivocal conditions, he says, "Of all these indications of the action of prussic acid, we have none in this instance." (p. 22).

We have now waded through this pamphlet, and we cannot help expressing our surprise that any reasonable man could ever come to the conclusion, from the moral, circumstantial, and medical evidence adduced in Tawell's case, that the deceased had not been poisoned by prussic acid. At first we were inclined to treat the pamphlet as a ruse—a sort of popular *ad captandum* article for a weekly newspaper—but we verily believe the author is quite serious in the whole of his *non sequiturs*. The mischief which a pamphlet like this is capable of doing, filled as it is with showy but unsound chemistry, and selected quotations from the works of French authors, who, if they were consulted, would most probably protest against the use made of them, has induced us to comment on the author's views at some length*. If his reasoning be correct, who can ever possibly be convicted of poisoning a fellow-creature by prussic acid, unless there be direct ocular evidence of the administration of the poison? The grand climax to his reasoning is, that the man who has not had a "fair trial," and has not been condemned on "conclusive evidence," has actually, it is credibly reported, confessed that he perpetrated a crime which the author proves, at least to his own satisfaction, that he could not possibly have committed—*Parturient mures et nascitur ridiculus mons*!

JOHANN LUKAS SCHOENLEIN, Privy

* In order to show how Mr. Strauss deals with his quotations and analogies, we may take a case which he quotes as having occurred at Chambéry, in 1841 (case of M. Pralet). This person was alleged to have died from prussic acid; but, observes Mr. Strauss, Orfila was called in to refute the evidence of two physicians and four chemists. There is not the slightest analogy between the two cases. There was no chemical evidence of the presence of prussic acid in this instance, and there was effusion of blood on the brain, which accounted for the symptoms.

Medical Councillor of Prussia, and Ordinary Professor of Therapeutics, and of Clinical Medicine, in Berlin, was born at Bamberg in the year 1793. After the usual preliminary studies, he graduated as physician at Würzburg in 1816, and four years later was appointed one of the *extraordinary* professors of that University. In 1824, he succeeded Dr. Friedreich in the chair of clinical medicine there, and also as medical director of the Julius Hospital, long renowned as a place of clinical instruction. Würzburg attained still higher consideration through the prelections of Schoenlein, and became the resort of a numerous concourse of students from all civilized lands. Ere long, however, in consequence of some misunderstanding with the Bavarian government, Schoenlein was obliged to abandon the scene of his labours, and betake himself to Zurich. Here he maintained his academic popularity. From thence he was invited to Berlin by the reigning sovereign of Prussia in the year 1840, where he possesses an ample field for pathological research.

The materials composing the volume of which the conclusion is now before us have been very ably selected and put together by Dr. Güterbock. The record commences with the last portion of Case 38, namely, one of ascites proceeding from hypertrophy of the spleen, tubercles in the lungs, and scrofulous phthisis of the kidney. Case 39 is one of diabetes mellitus in conjunction with pulmonary tubercles: some curious remarks are interpolated touching the cause of the formation of sugar. The next case is one of scarlatina, with violent angina, attended by extensive desquamation from both the internal and external surface of the body. Case 41 is erysipelas of the face complicated with delirium tremens; some observations are appended relative to the employment of cold affusion in that form of erysipelas, and the sequelæ of the disease. Case 42, the last of the series, is an apoplectic seizure, followed by palsy of the right half of the body, and pain in the right foot, treated by *nux vomica*, issues, and electro-magnetism.

We subjoin, by way of extract, Schoenlein's views touching scrofulous disease of the kidney:—

“This malady is one of great rarity.

I have not seen half a dozen cases of it; at least, where there has been a fatal termination. Although I believe it to be curable at the beginning, after it has reached a certain stage it is beyond the power of art. It is therefore important for the medical practitioner to be able to detect its presence. The primary phenomena resemble closely those of incipient pulmonary phthisis. Young persons are most prone to be attacked, as children of from 7 to 8 years old, even up to the period of puberty, who are of a strumous habit, or present marks of strumous affection of the external parts. Such individuals manifest, generally after exposure to cold and moisture, an affection of the urinary organs—at first indistinct, a feeling of pressure in one or both regions of the kidney, pain in the sacrum, rarely darting: on further examination it will be found that the pain is referred, not to the middle, but to the side of the vertebral column; there are frequent calls to void urine, especially during sojourn in a damp atmosphere of a low temperature. I have perceived that this urgency to micturition was aggravated at night (just as the cough in the instance of pulmonary tubercles); young children are apt to wet the bed, hence this habit ought to be watched when they are of a strumous disposition. The urine is, in the outset, pale, limpid, or else turbid from mucus, very like the tracheal secretion coughed up by phthisical patients at an early stage. Only when violent pain sets in will blood be discovered in the urine, periodical hæmaturia (akin to hæmoptysis). In individuals nearer puberty other symptoms are superadded, as erections, and painful retraction of the testicles, like what occurs in cases of stone in the bladder. The above are the characters of tubercular disease of the kidneys while susceptible of cure. The treatment ought to consist of local depletion, frictions with iodide of potassium, or iodide of mercury, over the region of the kidneys, saline baths, iodine internally by itself, or in mineral waters, with great attention to diet and drink—the last ought to be asses' or goats' milk mixed with mucil ge.”

(p. 392.)

Observations on Variola Vaccina, or Cow-Pock. By Sir MATTHEW J. TIERNEY, Bart. K.C.H. M.D. &c.

THIS little pamphlet appears at a very opportune moment, inasmuch as certain parties have been trying most unwarrantably to lower in general estimation the practice of vaccine inoculation. The inferior classes of society are slack enough in resorting to it; therefore any attempt to slight its importance cannot be too severely censured.

Sir Matthew seems to have been one of the first persons engaged in carrying out Dr. Jenner's invaluable discovery. Under the head of Instructions, he asserts that an accurate knowledge of the signs of infection, and of the character and progress of the vaccine vesicle, is essential to the success of inoculation. He points out the occasional deviations from the ordinary appearance and character; describes the spurious pustules which afford no security against small-pox, with their probable cause; the methods of taking vaccine matter, and of preserving and conveying it; the modes of inoculation; the constitutional symptoms, and appropriate medical treatment. Sir Matthew has embodied a statement of the formation of the first county vaccine institution, established in Sussex in the year 1804.

Essay upon Cretinism and Goitre. By E. WELLS, M.D. late Fellow of New College, Oxford; and Radcliffe Travelling Fellow. London, 1845. 8vo. pp. 69.

THIS essay owes its birth to a professional residence at Interlachen, whereby the writer had frequent opportunities of visiting the institution for the education of infant cretins, established upon the Abendberg, in the Canton of Berne, in the year 1840, by the benevolent Dr. Guggenbuhl. It comprises observations on the origin of the term cretinism, an account of the authors who have written upon cretinism, the description of a cretin, the proximate and predisposing causes, with the different forms of cretinism: the diseases to which cretins are liable, and concludes with the physical and moral education of the infant cretin. Cretinism the writer considers to be "a mental and bodily degeneration, having for its proximate cause an impoverished

condition of the blood, and for its predisposing cause, the damp, warm, and stagnant atmosphere of the Alpine valleys." p. 43.

In Chapter III. will be found a very graphic description of these misshapen beings; a portrait of one is prefixed by way of frontispiece. The necessity for good education during the tender years of life is cogently pointed out in Chapter VIII. We recommend the essay to those who wish to study this interesting subject.

MEDICAL GAZETTE.

Friday, April 4, 1845.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

RETROSPECTIVE EFFECT OF THE REGISTRATION CLAUSES.

MUCH needless alarm appears to have been excited among members of the profession, respecting the mode of registration to be adopted under the new Medical Reform Bill. A report has been widely circulated, to the effect that, as the bill stands, the present members of the London College of Surgeons would not be permitted to register as "Surgeons," but merely as "Licentiates in medicine and surgery." This has been complained of as a grievous injustice; and such undoubtedly we should regard it, if there were any grounds for believing that this was the intention of the framers of the bill. The result would be, that under the new act there would be no "Surgeons," except those who had been already admitted as Fellows of the London College. The act would thus become retrospectively penal. Every individual possessing the diploma of the London College of Surgeons would be compelled to forego any privileges derived from that document, and sink to the status of an apothecary, without retaining even the title of surgeon.

That such has been the view taken by many, of the thirty-second clause of the new bill, is evident from the numerous letters which have appeared in the medical journals, and which have been addressed to us on the subject. In a recent number of the Provincial Medical and Surgical Journal, we find a letter embodying the sentiments of the practitioners of Reading, in which the writer infers "that those who are now practising as surgeons and apothecaries, registered under the new Bill, will *lose* their title as surgeons, and *drop* down to licentiates in medicine and surgery. This appears hard, considering the position in which the bulk of the profession is placed by the recent decision of the Council of the College of Surgeons, and must be surely amended" (!) The writer then goes on to suggest a remedy:—"Supposing we are correct, might not an addition be made to the Registration Clause, allowing all who have been so many years in practice, being members both of the College and Hall, to retain the title of Surgeon; otherwise, unless compelled, we cannot give it up."

If the grievance really existed, this proposed remedy would certainly not remove it. The injustice of such an act as that of depriving a member of the College of his diploma (for it would virtually amount to this) would not be diminished by the fact that the deprivation extended to those only who had recently been admitted members. If such a rule were to be adopted, what number of years of practice could be fixed, with any show of equity, in order to entitle a man to claim beyond his brethren an exemption from this spoliation of his rights? It is the possession of the diploma, and not merely the length of time that it may have been held by a member, which gives him an indefeasible claim to hold it with all its privileges for ever: and among these

privileges is assuredly that of retaining the title of "surgeon."

It must be borne in mind, however, that there are many now practising as "surgeons and apothecaries" who will have no claim whatever to be registered as "surgeons" under the Bill. There is nothing at present to prevent a licentiate of the Hall from calling himself a surgeon, and many are practising under this denomination; but such a person will not of course be entitled to registration under any other form than that of licentiate in medicine and surgery.

The clauses relating to registration, under the new bill, are two in number, the 13th and 32nd. We shall take the last first, because it relates exclusively to the registration of those persons who are *now* engaged in the practice of medicine and surgery. We subjoin the clause:—

"Provided always, and be it enacted, that it shall be lawful for the said Council, on the application of any person legally practising or entitled to practise at the *end of this Session of Parliament*, as a Physician or Surgeon in any part of the United Kingdom of Great Britain and Ireland, or as an Apothecary in England, to cause the name of such person to be registered as a physician, surgeon, or licentiate in medicine and surgery, as the case may be, on production to the said Council of his diploma, license, or certificate, or such other proof as shall be satisfactory to the said Council, that at the *end of this Session of Parliament* he was so practising, or legally entitled to practise, and on payment of a fee of *Twenty Shillings* in the case of Fellows or Associates of the said Colleges of Physicians and Surgeons respectively, and of *Five Shillings* in every other case, which fees shall be applied toward the expenses of this Act; and during *twelve* calendar months after the *passing of this Act*, every person legally practising or entitled to practise at the *end of this Session of Parliament* as a Physician or Surgeon in any part of the said United Kingdom, or as an Apothecary in England, and during the period of

Two years after the passing of this Act, every person legally practising or entitled to practise at the *end of this Session of Parliament* as a Physician, Surgeon, or Apothecary, in any of Her Majesty's Colonies and Foreign Possessions, although not registered, shall continue to enjoy the same privileges and exemptions, and be qualified to be appointed to the same offices, and to practise in the same manner, as if this Act had not been passed, and no further or otherwise, unless registered under this Act."

The clause is evidently clumsily constructed, and is well calculated to give rise to some ambiguity. Aiming at brevity (not a common fault in Parliamentary documents), the language renders the real meaning of the clause obscure. It is first laid down that every legal practitioner of medicine may, on application, be registered as physician, surgeon, or licentiate, according to his diploma, license, or certificate or (in order to include those who were in practice before 1815) on some other proof that he is legally entitled to practise. So far the statement is clear, but then we come to the payment of a fee for this registration, and here it is laid down, that the fee shall be *twenty shillings* in the case of *Fellows or Associates of the said Colleges of Physicians and Surgeons respectively*, — omitting all reference to the *Members* of the Royal College of Surgeons, who form the great bulk of the profession. Licentiates of the Apothecaries' Company, and those who were in practice before 1815, will be registered on the payment of a fee of five shillings.

We believe that it must have been by accident, and through the ignorance of the party who drew the clause, that *Members* of the Royal College of Surgeons were not specially mentioned. He must have known so little of the profession, as to suppose that all "Surgeons" were necessarily *Fellows or Associates* of the College. We are inclined to put this interpretation upon

the omission, from the reply which has been given by the Secretary of State to Mr. Craddock, and others. The correspondence on this subject will be found at p. 813 of this volume. Whatever may be contained in the present Bill, the intentions of Sir James Graham respecting registration, as expressed in his letter to Mr. Craddock, are:—

1. A man holding the diploma of the College of Surgeons can only register himself as a "surgeon,"—but he may act as, and enjoy all the privileges of, a general practitioner.

2. A man holding the license of Apothecaries' Hall, although he may have hitherto styled himself "surgeon," can only be registered as a licentiate in medicine and surgery. Like the registered surgeon, he may act as, and enjoy all the privileges of, a general practitioner.

3. A man holding the diploma of the College of Surgeons, as well as the license of Apothecaries' Hall, must make his election. He can only be registered either as "surgeon," or "licentiate in medicine and surgery." No limits are, however, placed on his practice: he enjoys all the privileges of the two classes.

With respect to "*physicians*," the right to register will depend upon the power to practise *legally* as a physician, conveyed by the diploma or license of any of the Colleges of Great Britain or Ireland. The holders of foreign diplomas, having no legal status as physicians in this country, cannot be registered until these diplomas have been recognised, and a license to practise granted by some one of the British Colleges.

Such, we believe, will be the retrospective operation of the clause in the new bill, so far as persons now practising are concerned. Under 3, we find that a man holding the diploma of the College, and the license of the Hall, can only be registered as surgeon *or*

licentiate. In the correspondence above alluded to, we are informed "that the bill does not contemplate double registration, nor would any thing be gained by it." We cannot exactly perceive why those who now legally enjoy a double title may not be allowed, if they please, to retain it under a double registration. There is some merit in a man having gained two diplomas, and it appears like an act of injustice to deprive him of one; for although nothing could be gained in respect to the privileges of practice, yet it is substantially taking from him one of those testimonials which it may have cost him some years of extra labour to acquire. In the opinion of the public, so far as the register is likely to be consulted, a man whose name is *doubly* registered may possibly stand better than one who has only a single qualification; just as, at the present time, the diploma of the College of Surgeons is sought after by candidates more to acquire honour by a double qualification, than as a document necessary to enable them to practise. We therefore doubt the assertion that "nothing would be gained by it;" it might as well be contended that nothing is now gained by a man holding the diploma of the College of Surgeons. Whatever may be done prospectively on this subject, we think that it should be left optional with the present race of practitioners to register under one or two denominations. The only inconvenience which we can contemplate is, that it will add to the bulk of the printed register. If the double registration be denied, those who have been working for years in order to obtain the license of the Hall, at a great expenditure of time and money, will be placed in a worse position than if they had, at less cost and labour, aspired only to the College diploma. All who possess this will become at once general practi-

tioners, with a power to register in the higher rank as "surgeons." They will thus have all the privileges of the licentiate of the Hall without having earned them; and, so far as the register is concerned, they will appear with a better title than the holder of a double qualification, who may register himself only as a licentiate.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, March 25, 1845.

DR. CHAMBERS, F.R.S. PRESIDENT,
IN THE CHAIR.

On the Minute Structure of the Lungs, and the Formation of Pulmonary Tubercle; with some Observations on its Detection by a Microscopic Examination of the Sputa. By GEORGE RAINEY, M.R.C.S. Communicated by R. D. GRAINGER, Esq.

THE author, in his prefatory remarks, observes that it is not his intention to introduce any new speculations on the structure, functions, and pathology of the lungs, but only to bring forward such facts as readily admit of verification by the microscope, and to deduce from them what he considers obvious and legitimate inferences.

He divides his subject into four parts: 1st, the anatomy of the lungs as applicable to their physiology; 2d, with reference to their pathology; 3d, the mode of formation of tubercle; and lastly, its detection by a microscopic examination of the sputa.

The first division contains a general description of the lungs of the reptile, shewing the alterations they undergo as they approach in complexity the same organs in the mammal. The principal difference between the lungs of reptiles and mammals is the existence of a double layer of vessels between contiguous air cells in the former, and only a single one in the latter.

The author showed that a great difference of vascularity exists in the different parts of the same lung, those parts being least vascular which are furthest from the principal air tubes; consequently, the quantity of blood requiring the influence of the inspired air is adapted to the diminution of oxygen in the remote cells; in which he considers the renovation of their contents is due more to the law of diffusion than to mechanical dilatation and contraction of the chest.

The author describes minutely the manner in which the bronchial passages communicate with the air cells and with each other; the actual terminus of a bronchial passage

being itself a cell at the surface of a lobule, or several cells connecting one bronchial passage with another. It is further shown that each plexus of capillaries is situated in a fold of membrane forming the immediate wall of the air cells; hence the author infers there must be cellular tissue in the lungs connecting these folds of membrane together.

He combats the opinion of Mr. Addison with respect to the non-existence of air cells in the foetal lung, and shows by microscopic preparations that this opinion must be erroneous. He is inclined to deny the existence of muscular structure in the minute bronchial tubes, both from the absence of anything like muscular fibre in the pulmonary membrane, and also from the fact that the connection of the bronchi with the cells appears to be such as not to admit of any constriction of these passages, even were muscular fibre present.

A description is next given of the manner in which tubercle is formed by the deposit of tubercular matter in the air cells, occasioning by its pressure absorption of the intervening capillary plexuses, the membrane still remaining. The author remarks that the vessels close to a tubercle, and even those of the cells in which the deposit is not sufficient to cause their obstruction, retain perfectly their natural character, while those near to cells filled with fibrine from inflammation have a tortuous and knotted appearance; hence he thinks the deposit is not the result of inflammation, but merely an altered secretion. The observations on the formation of tubercle are confined to those of which the author has had the best opportunities of examining. He considers that it is only in preparations of the injected lung that the exact extent and situation of tubercular matter can with certainty be ascertained: he offers no opinion respecting miliary tubercle, having only once examined it; but the facts respecting the formation of common tubercle the author considers are unconnected with the consideration of any other form of phthisis, inasmuch as his preparations exhibit the tubercular deposit in all the different stages of common tubercle, from a quantity so small as to fill only a small part of a cell, up to that filling one, two, or even an indefinite number of cells: in all these preparations the tubercular deposit exhibits the same microscopic character.

Lastly, (from the fact that the pulmonary membrane does not become absorbed) the author proposes a method of detecting tubercular matter by a microscopic examination of the sputa. Although the observations he has made are not sufficient to enable him to speak with confidence of the practicability of this mode of diagnosis, in one

instance he succeeded in detecting the pulmonary membrane in tubercular matter washed from the trachea of a phthisical patient, with perfect ease and certainty.

Mr. Grainger bore testimony to the accuracy of the facts, and the correctness of description of the preparation mentioned in Mr. Rainey's paper. This accuracy, rather than the novelty of the views advanced, constituted the novelty of the paper, and particularly so as previous accounts of the anatomy of the lungs were deficient in exactness. Mr. Grainger then, at some length, shewed what he considered to be the facts established by the paper, and which will be found in the abstract.

Dr. C. J. B. Williams was of opinion that the portion of the paper which treated of the minute anatomy of the lungs confirmed the description of M. Bourguery, and corresponded nearly with the observations of Mr. Addison; observations which, however valuable in themselves, did not warrant the conclusions which that gentleman had drawn from them, as far as respected the first formative process of the cellular texture of the lung. He (Dr. W.) could not assent to the portion of Mr. Rainey's paper on the pathology of the lung, especially in reference to the surface of the air cells being the primary seat of the deposition of tubercle. To discover this seat in so fine an organ as the lung it was necessary to investigate a number of cases of the deposition of tubercle in its very early stage, before it had accumulated and made its way through the epithelium to the free surface of the cells. Mr. Rainey, however, acknowledged that he had examined one specimen only of miliary or incipient tubercle. On the contrary, Mr. Gulliver had unequivocally detected the opaque granular matter of tubercle in many cases in the walls of the cells, and, indeed, the plexus of vessels itself. Some of Mr. Addison's remarks were to the same effect, but he, like Mr. Rainey, had conceived the idea that tubercle was essentially altered epithelium. That tubercular matter, however, was not an altered condition of the mucous membranes was proved sufficiently by the circumstance that tubercles were found in the parenchymatous structure of organs that were without mucous membrane; such, for instance, as the spleen, the brain, in serous membranes, and in blood-vessels. He believed that the nature and origin of tubercle might be easily explained in another manner. Mr. Rainey, in his observations on the obliteration of the blood-vessels of the lung by tuberculous deposit, had been forestalled by several physiologists, particularly by M. Nalatis Guillot, whose researches proved that the obliterated vessels were often compensated by anastomosing vessels, not

only in the remaining healthy texture of the lung, but also in the pleura, and even in the outer wall of the chest itself through adhesions to the costal pleura. This fact clearly explained how it was that a few leeches, or a blister applied to the walls of the chest, often afforded such great relief in phthisis. He (Dr. W.) was surprised that the author had thought it necessary to make any observations with the view of disproving the muscularity of the pulmonary texture, the non-existence of which had been sufficiently established by his (Dr. W.'s) researches and experiments. These experiments had shown that galvanism produced no contraction in the vesicular part of the lungs, although the contractions of this agent were most evident in the bronchial tubes. He thought little of Mr. Rainey's microscopic test of the sputa. This test could only be applied during the latter stage of the disease, and after many other unequivocal signs had decided the true nature of the disease.

Dr. Kingston said that one point of interest to him, in the excellent paper that had been read, was the confirmation it afforded of the observations which he had published some years ago in the Transactions of the Society, on the vascularity of pulmonary tubercle. He had stated, what M. Lugol, of Paris, had subsequently confirmed by very extensive observation, that red vessels are sometimes to be seen under the microscope in pulmonary tubercle. The beautiful injections of tuberculated lungs, made by Mr. Rainey, afforded the same result. In some instances the tubercles admitted the injection, and displayed their vascularity; in others they had not. The invisibility of the vessels in many of the tubercles examined by Dr. Kingston, and the frequent failure of Mr. Rainey's injections to penetrate them, were owing to the extreme minuteness of the nutrient vessels of tubercles, which, except under great congestion or inflammation, did not carry red blood. Where their vessels were apparent, they appeared to be arranged in subservience to nutrition, and instrumental by their action at first, and their obstruction afterwards, in producing the various changes which took place in the progress of tubercle.

Mr. Prescott Hewett did not see how the last speaker could think that the views expressed by the author of the paper concerning the vascularity of tubercular matter agreed with his own. Mr. Rainey concluded that tubercular matter was not vascular; Dr. Kingston considered that it was. The minute vessels sometimes seen in a tubercle did not, in fact, belong to it, but were connected with the neighbouring tissues which had been entangled in the morbid deposit. In a carefully injected liver filled with large tubercles, Mr. Hewett only found

one or two small vessels passing into the tubercular matter, and this occurred only in one or two tubercles. In all the others a distinct areola of vessels might be observed encircling them so completely that the vessels of the normal tissue seemed as though they had been pushed out of their places and compressed together by the deposition of the morbid substance. Regarding the deposit of tubercular matter on the free surface of a mucous membrane, he was of opinion, with Dr. Williams, that the views of the author ought to be received with great caution, especially as Mr. Rainey had only once examined some milary tubercle under the microscope. Mr. Hewett then observed how Dr. Carswell had been mistaken upon this very point. In the pathological plates of that author was a specimen of a serofulous kidney supposed to be illustrative of the deposition of tuberculous matter upon the free surface of a mucous membrane. He (Mr. H.) had examined several similar specimens in an early stage, and had often found tubercular matter in the sub-mucous cellular tissue, the mucous membrane itself being healthy. In two or three instances also in which the mucous membrane was partially destroyed by ulceration, the tubercular matter apparently was situated upon its free surface. In the advanced stage of the disease mucous membrane had disappeared altogether. The course taken by the disease was traceable in the bladder, when it had so far extended, as all the appearances just mentioned he had several times seen in that organ. True it was that tuberculous matter was sometimes deposited upon the free surface of a mucous membrane, but this was not always the case.

Dr. Hodgkin agreed with Dr. Williams respecting the seat of tubercular deposit. He had met with this matter on the surface of glands, and in cellular membrane.

Dr. Golding Bird remarked, that Mr. Rainey appeared to have arrived at the conclusion that the lining membrane of the air-cells was truly a mucous membrane. Its pathology, however, would not seem to warrant such a conclusion. A mucous membrane during inflammation secreted mucus destitute of pus or coagulable albumen; but the lining membrane of the air-cells, in common pneumonia, poured out a quantity of albumen, and hence the scanty yellow, or rust-coloured sputa of pneumonia, coagulated when heat was applied. In the condition of grey hepatization, also, occasionally, in persons of weak power, left long after the subsidence of the acute stage, the cells were full of a substance resembling in every particular coagulated albumen. Hence, although anatomically the lining membrane of the air-cells could not be considered a serous membrane, its pathology, he believed, ap-

proached more nearly to such a structure than to a mucous membrane. He agreed in the remark of Dr. Hodgkin that it was almost impossible to discriminate between the deposit in the air-cells resulting from pneumonia, and the so-called tubercle. The microscopic test of the sputa, mentioned by Mr. Rainey, was not a novel one, and even the presence of portions of air-cell in the expectorated matter had been pointed out some time since by Dr. Buhlman, of Berne, a pupil of Professor Valentin. He had, in his Thesis on the Microscopical Structure of Expectorated Matter, figured broken air-cells as found in the sputa of a phthisical patient, mixed with flakes of cholesterine.

MICROSCOPICAL SOCIETY.

March 19, 1845.

PROFESSOR BELL, F.R.S. &c. PRESIDENT
IN THE CHAIR.

A PAPER, by Alfred Smee, Esq. F.R.S. "On Vessels in Fat smaller than the Capillaries," was read. This paper was a continuation of a former one.

Mr. Smee commenced by stating that although it was extremely difficult to ascertain precisely the original size of the capillaries, he was about to describe in the present paper another system of vessels so much smaller that it is impossible to attribute their diminutive size to any shrinking of those vessels; they are given off from them, and are distributed at every angle of each cell of fat. To these vessels he proposes to give the name of *vasa adipis*, as clearly pointing them out as appendages to fat, and also as preventing their being mistaken for the *vasa serosa* of some anatomists; the existence of which is, however, in his opinion, very problematical. The vessels now described are very minute, measuring from about $\frac{1}{10000}$ to $\frac{1}{25000}$ of an inch in diameter. They are found in every kind of fat when in its highest state of development, but do not appear until then. They exist only in fat the globules of which have assumed their polygonal form, so that it would appear the last process for the development of fat in its perfect state is the production of these minute appendages to the capillary system. It must, however, be borne in mind, that, although the term vessel has been applied to them, no evidence whatever can be adduced either of the existence of a cavity or of distinct walls. The term *vasa* is here applied to denote that a certain part exists in a definite position with certain boundaries, permeable by fluid injections, and possessing generally tolerably regular dimensions. It would also appear that their formation depends upon the two sides of contiguous vesicles leaving at their

angles a little space, which becomes converted into one of these minute vessels. Nothing has been ascertained with respect to their office.

Another paper, by Edwin Lankester, M.D. F.L.S. Esq. &c. "On some Abnormal Forms of Fungi, with Remarks on their Morphology," was read.

The fungus which led to these remarks was found by Dr. Lankester in the neighbourhood of Cheshunt, in December 1844. It was a specimen of the *agaricus personatus*, which was in a decaying state from the effects of a previous frost. It exhibited in all its parts a normal structure, with the exception of the pileus, in the centre of which, immediately over the insertion of the stipes into the hymenium, a second and smaller hymenium was developed. The gills of this were apparent, and directed towards the light; its edges were covered with a villus, which gradually united itself with that of the lower hymenium. There was, however, no appearance of any development of a stipes. On making a section of the whole plant no connection between the lower and upper hymenium was discoverable, so that the latter was evidently an independent development. Although in too dry a state to exhibit under the microscope much of the peculiarities of structure of this class of bodies, sufficient was seen to prove that, whatever might have been the character of the lower or normal hymenium, the upper one was of precisely the same nature. In accounting for this appearance, Dr. Lankester considered that in the fungi the pileus and stipes were to be regarded as the representatives of the leaves or nutritive organs in the higher plants, and the hymenium as the analogue of the flower, or reproductive organs, and consequently that the influence of cold, or of some other external agent, causing an arrest of development in the vegetable tissue of the fungus, would be attended with the development of reproductive tissue, such as we know occurs under similar circumstances in the higher forms of plants. That this view of the office of the parts is correct, he considered might be made out by passing from the fungi to the lichens, from these to the hepaticæ, mosses, and ferns, in which the green parts are undoubtedly the nutritive tissue of the plant, and the analogues of the leaves. In the fungi, however, it would appear that the whole body must be looked upon as the analogue of the flower in the higher plants, the thallus being in this family at its minimum of development. Hence, then, just as the calyx and corolla stand in the relation of nutritive organs to the more especially reproductive stamens and pistils, so the pileus and stipes stand in a similar relation to the hymenium. He

concluded with some observations upon other abnormal forms of fungi, one of which, figured by Schoffer, which presents two smaller fungi growing upon the pilius of a larger one, he considered to be produced in the same manner as double seeds or proli-ferous flowers.

ment, would render the bill just to the pro-fession, and additionally safe to the com-munity at large.

MEMORIAL OF THE WOOLWICH PRACTITIONERS.

*To the Rt. Hon. Sir James Graham, Bart.
&c. &c.*

The Humble Memorial of the undersigned legally-authorized Medical and Surgical Practitioners of Woolwich, in the County of Kent,

Sheweth,—That your Memorialists feel grateful for your taking into consideration the present anomalous state of the medical profession, and for introducing a bill into parliament to regulate the practice of physic and surgery throughout the United King-dom.

That your Memorialists, having carefully considered the clauses of the said bill, are of opinion that the operation of the measure would be more satisfactory to the profession, and beneficial to the public, if provision were made therein that a part of the Council of Health be chosen from that class of medical practitioners to be termed licentiates in medicine and surgery, inasmuch as they are by far the most numerous, and, being entrusted with the health of a great majority of the public, consider they should have a share in making those laws by which they are to be hereafter governed.

Your Memorialists respectfully declare their belief that the relaxation of any existing penalties on unlicensed practice would tend to degrade and injure properly educated and qualified practitioners, by admitting to competition with them a multitude of igno-rant pretenders to medical and surgical knowledge, who, by insuring immediate pay-ment, would elude that part of the bill which incapacitates them to recover in a court of law.

Your Memorialists also consider that the public would be greatly injured by not pos-sessing a full and efficient protection against unlicensed practice, and that the poor, the unwary, and the credulous, would be left unprotected against the artifices of ignorant and reckless empiries.

Finally, your Memorialists beg to express their conviction, that the insertion of a clause, during the progress of the bill in committee, whereby the "visiting, prescribing, or treating diseases or bodily injuries for gain or emolument" might be made a misde-meanour, punishable by fine or imprison-

MEETING OF THE BIRMINGHAM AND MIDLAND DISTRICTS MEDICAL AND SURGICAL ASSOCIATION.

A HIGHLY respectable meeting of the Medical and Surgical Association of Bir-mingham and the Midland districts was held at Queen's College on Thursday last, to receive the Report of the Sub-committee on the Bill of Sir James Graham, for regulating the Profession of Physic and Surgery. The Chair was occupied by Dr. Birt Davies, the President; Dr. Male, though present at the meeting, being unable to preside though indisposition.—After a lengthened discussion, in which Dr. Bell Fletcher, Dr. Melson, Dr. Mackay, Mr. Davies, sen., Coleshill; Mr. W. Under-hill, jun. Tipton; Mr. Green, Mr. Knowles, Mr. F. Elkington, Mr. Harmar, Mr. San-ders, and other members, took part, it was resolved unanimously—"That the Report of the Sub-committee be adopted by this meeting, and that a copy of the Report, signed by George Edward Male, M.D. the President of the Association, be transmitted to the Right Hon. Sir James Graham by the Honorary Secretary." The following is a copy of the Report:—

"The Sub-committee appointed by the Birmingham and Midland Districts Medical and Surgical Association, having ascertained that the bill laid on the table of the House of Commons at the close of the last session was not likely to be again submitted to Parliament without considerable modifica-tion, have deemed it preferable to delay bringing the members of the Society together to receive their Report until they were enabled to lay before them a copy of the bill in the amended form in which it should ultimately be introduced by the government; and after a careful consideration of the last bill, as printed by order of the House of Commons on the 25th of January last, your Committee report, that according to their construction the objects it is proposed to attain by the bill in question are as follows:—1. To discriminate and to distinguish all persons who at the time when the bill shall come into operation may be found legally qualified to practise Medicine and Surgery.

2. To secure by adequate tests the possession of a certain *minimum* in the attainments of all hereafter desirous of acquiring a right to practise in any medical or surgical capacity; which *minimum* shall be one highly respectable in its extent, and uniform in kind; and in like manner to provide in addition an uniform and more elevated standard for all such as possess ability, time, and capital, for attaining to the *summos honores* in Medicine and Surgery.—3. To register all persons qualified to practise Medicine and Surgery, according to their respective grades, in an official record which shall be authoritative and easy of access; giving to every person so registered a right to practise, under certain conditions, in every part of the United Kingdom.—4. To make the introduction of these arrangements prospective, and, as far as may be possible, without prejudice to existing rights.—5. To recognise in a medical or surgical capacity for the public services of the State in the Supreme Courts, in the minor tribunals, and in the public institutions, those practitioners only who shall have been duly registered under the Act proposed.—6. To exempt the practice of Medicine and Surgery in all other particulars from the restraints of preceding statutes or charters; but to leave it subject, as at present, to the remedy by a civil action for the consequences of a *mal-praxis*, and responsible, as at present, to the criminal law whenever a death shall be proved to have occurred through a culpable neglect or ignorance. The power of the Apothecaries' Company to prosecute for an infringement of their privileges is also left as heretofore; and powers are given for punishing, by fine and imprisonment, whoever shall be convicted of assuming any medical or surgical style, title, or designation, if not duly registered.—7. Lastly, by the machinery of a Council of Health, it is proposed to bring all the existing bodies who are concerned in medical and surgical education throughout Great Britain under one central authority, of which it shall be the function to render their proceedings uniform, restrain the tendencies of corporate and of individual interest within proper bounds, and place the entire profession throughout the empire in a clear and definite relation to the State.

"The objects thus contemplated by the bill now before Parliament appear to your Committee to embrace the chief, if not the whole, of the great points upon which it would seem advantageous, expedient, and practicable that the legislature should, at the present time, interfere by statute in regulating the education, conduct, and privileges of the medical and surgical profession. And, after giving their best consideration to the subject, your Committee

desire to express their entire and zealous adoption of the general principles that pervade Sir James Graham's bill. But in thus concurring in those great and enlightened objects, they deem it proper to call the attention of the Society to one or two points of its practical operation in regard to which the bill may probably be susceptible of improvement.

"Respecting the offences relative to registration contemplated by the bill, your Committee would desire to see the courts distinctly specified which are to take cognizance of such offences, inasmuch as it seems to be extremely necessary that the punishment of every such offence, if susceptible of proof, should be certain, cheap, and summary; and that the invidious duty of prosecution should not be left to the extremes of zeal or indifference on the part of individuals, but always discharged under the authority, immediate or delegated, of the central power.

"Your Committee are further of opinion that the penalties attached to false pretences of qualification should, if possible, be extended to all practice in medicine and surgery by unqualified parties, and apply alike to the registered and to the unregistered; for if limited, as is proposed, to the latter only, the mere fact of registration in any grade would prevent the imposition of the penalty intended, and form a valid plea in answer of a charge of delusively pretending to higher honours to which the party had in truth no claim.

"Lastly, entertaining a strong opinion that the State is not at liberty to use for purposes merely fiscal any resources which are destructive to life, or detrimental to the health or morals of the community, your Committee desire to express their regret that no provision has been made by this bill for the suppression—either immediately or prospectively—of nostrums and secret remedies, many of which are known to exercise a baneful influence on vast numbers of ignorant and credulous persons, and for which injury the revenue produced by the stamps on such articles would seem to afford a very trifling and inadequate equivalent.

"In conclusion, your Committee desire to express their gratitude to Sir James Graham for the very able and satisfactory measure brought forward by him on a subject affecting a great variety of interests, and beset by many difficulties—a measure which they feel assured has been framed in an impartial spirit, and without other view than that of promoting the welfare of the community at large. And they recommend to the Society to adopt active measures for obtaining the support and assistance of the members of the legislature connected with

the Birmingham and Midland district in passing this bill into a law.

REGULATIONS RESPECTING SAGES-FEMMES IN PARIS.

[We extract the following paper from the *Gazette Médicale*, in order to show how strict our neighbours are in the admission of females to practise midwifery. A great reform is on the point of being carried out, in consequence of its having been discovered by Orfila that many licensed and diplomated female practitioners in midwifery could neither read nor write. In England, where the number of these practitioners probably exceeds a thousand, there is no sort of restraint placed upon them. There is no government order for testing their knowledge either in grammar or midwifery! —*ED. GAZ.*]

Before the Clinical Hospital was established, sages-femmes were admitted to an examination in midwifery on simply presenting two certificates,—one of good moral conduct, and the other showing that they had attended a theoretical course of lectures on midwifery, delivered by a professor of the Faculty, and a second course under a private professor, or a sage-femme en chef. Practical instruction seems to have been but little attended to. It was not even ascertained whether the candidate could read and write; and loud complaints were made, that medical diplomas should have been issued to persons who had received no instruction, and “who were unable to write a few lines, without making many grammatical mistakes.”

On the establishment of the Clinical Hospital, M. Orfila was determined to put an end to the disgrace thus brought on the obstetric art; and regulations of a stringent kind were made and adopted, in order to control the admission of sages-femmes, in respect to the privileges of practice.

Thus, to obtain admission to the Clinical Hospital, the female pupil must undergo an examination:—She is made to write under dictation, and is then compelled to read what she has written. If the results be satisfactory, and she is of good moral conduct, she is admitted; if otherwise, she is rejected, or remanded for six months, in order that she may improve herself. Out of 45 who presented themselves for examination, only 7 were admitted, 3 remanded, and 35 were rejected. This regulation respecting

reading and writing is founded on a government order of the year 1807.

On admission, the pupil is compelled to attend two courses on the theory and practice of midwifery, one by a male and the other by a female professor. The pupils are divided into classes, and attend in the wards night and day. They are exercised in the “*toucher*” by the “*sage-femme en chef*,” and they have all the deliveries which occur during the night. The day-deliveries are superintended by the male pupils. They are further instructed in the treatment of women and children during and after parturition; and if they conduct themselves well for an entire year, they are admitted to a preliminary examination. Well satisfied with the beneficial results which have attended this plan at the Clinical Hospital, Orfila is endeavouring to work out the same reform in other establishments where sages-femmes are received; and it is probable that before long the system will become universal in Paris, and it will then be extended to the provinces. Hence, in a few years, obstetric diplomas will be held only by those sages-femmes who can read and write, and who have gone through regular courses of practical as well as theoretical instruction in midwifery.—*Gazette Médicale*, Mars 1845.

POISONING BY BREAD CONTAINING ERGOT OF RYE.

At the meeting of the Academy of Sciences on January 13th, a note was read from M. Bonjean, in continuation of a former communication, detailing the consequences which had resulted to a family from the use of bread containing ergot of rye.

M. Bonjean's letter gives an account of the autopsy of a child, aged 10 years, and who had undergone the operation of amputation about five weeks before death. The examination of the body was made by Dr. Pétrequin, principal surgeon to the Hôtel Dieu at Lyons.

The brain was healthy; the meningeal veins were much distended; but the membranes of the brain were not diseased. A dessert-spoonful of rose-coloured serosity was found in each lateral ventricle. The two inferior thirds of the right lung were in an advanced stage of pneumonia, and the remaining third in the second stage; the anterior and superficial part of this lung presented a single abscess, capable of containing a hen's egg. The left lung was in the first stage of pneumonia. There were neither tubercles nor small abscesses. The liver was in a perfectly normal state.

The veins of the stumps were healthy; the arteries were converted into fibrous cords for the space of about $1\frac{1}{4}$ inches from

their cut extremities, but they presented no other alteration. The nerves were thickened for some distance towards the part where they had been incised; elsewhere they appeared healthy. — *Comptes Rendus*, January 13th.

POISONING BY SULPHURIC ACID.

WE copy the following from the Times' Report. We shall be glad if any of our correspondents at Exeter can furnish us with the particulars of the case, which was tried before Mr. Justice Erle.

Western Circuit, Exeter, March 22.

Samuel Haydon was indicted for the wilful murder of Mary Haydon, his daughter, on the 19th of February.

The death was occasioned by vitriol having been poured down the child's throat, but it appeared that in that neighbourhood the poorer classes of the people were in the habit of using vitriol for many diseases.

After a lengthened trial, the Jury *acquitted* the prisoner.

[What strikes us as extraordinary in the case is, that the fact of the poorer classes of the people being "*in the habit of using vitriol for many diseases*," should be put forth as any sort of justification for a man pouring that liquid down his child's throat! This would argue the existence of a deplorable degree of ignorance in that part of England; for we should have supposed that there could have been no grown-up person who was not aware that a corrosive liquid like vitriol could not be poured down the throat of a young child, under whatever pretence, without endangering or destroying life.—*Ed. Gaz.*]

RESEARCHES

UPON THE POISONOUS EFFECTS OF SULPHATE OF QUININE.

By M. DESIDERIO.

THE conclusions deduced by the author from his numerous experiments upon animals, as well as clinical observations, are the following:—

The effects of large doses of sulphate of quinine upon the lower animals are similar in almost every respect to those witnessed in the human subject, and consist in lethargy, difficulty in maintaining the erect posture, tendency to immobility, impaired vision, falling of the eyelids.

Acetate of morphine and alcohol produce analogous effects, and if administered will consequently augment the deleterious influence of the sulphate of quinine.

On the contrary, cherry-laurel water produces an opposite effect, and within

certain limits may be considered as an antidote.

Venesection acts still more beneficially in cases of poisoning by the sulphate of quinine.

The powder of the digitalis purpurea has also appeared to exert a favourable influence in the cases referred to.—*Comptes Rendus*, February 10th.

SUDDEN ACCESS OF INSANITY.

THE following is a singular instance of the suddenness with which an attack of insanity may come on: it occurred recently at Paris. An engraver, after having spent twenty years on the engraving of a portrait, took the proofs to a publisher, who had agreed to purchase the plate. In the course of conversation some disparaging observations were made on the work. The engraver rushed into an adjoining room, and dashed his head violently against a stone chimney-piece, producing severe injury to the head, on a recovery from which it was found that his reason was entirely gone.

It was long since remarked by the celebrated Pinel, that persons endowed with highly sensitive feelings, might, by any sudden or violent emotion, be immediately deprived of understanding. Thus an attack of insanity may be caused in a moment, by extreme joy or terror. He gives the following curious instances.

During the French Revolution, an artilleryman proposed to the Council of Public Safety a new piece of artillery, which he had invented, and which was to have the most deadly effects in war. A day was appointed for the trial of this invention at Meudon, and Robespierre wrote a letter to the inventor, and expressed his approbation of the invention in very flattering terms. The man to whom it was addressed became motionless on reading it, and he was soon afterwards sent to the Bicêtre, in a state of complete dementia.

About the same time, two young men, brothers, entered the army, and during a bloody action one of them was killed by the side of his brother. The latter became instantly motionless like a statue, and lost his reason. He was conveyed to his father's house, and at the sight of him, a third son, owing to the shock produced by the death of one of his brothers and the insanity of the other, became also insane. They were for many years confined at the Bicêtre under the care of Pinel.

There is a well-known case related by Mr. Travers, (*Constitutional Irritation*), of a young lady, who was found one morning in a state of complete dementia playing with the fingers of a skeleton, which had been

placed in her bed the night before. The terror produced by the sight of the skeleton had suddenly caused the attack.

Not long since there was reported in this journal the case of a naval officer in the command of one of the ships lately forming the squadron off Cork. He suddenly rushed on deck, ordered the ship to be cleared for action, and the guns to be pointed and fired on the town. So little was insanity suspected, that his orders were about to be obeyed, when, fortunately, it was resolved to delay the execution until they were confirmed by his superior in command. It was found that this officer had been attacked with mania, the cause of which did not appear, but as it was not brought on by any sudden or violent emotion, it may have been in this instance long dormant.

The sudden occurrence of dementia, under the circumstances above mentioned, renders it difficult to suppose that this form of insanity is in all cases necessarily dependent on physical changes in the brain.

ON QUARANTINE,

AS APPLIED TO THE PREVENTION
OF THE PLAGUE.

By M. AUBERT ROCHE.

THE author, after having traced the various changes which the system of quarantine has undergone in several countries, proceeds to inquire into the effects as regards France, in a commercial and financial point of view, and concludes, that quarantine exists only to the general detriment of the interests of France. With respect to the public health, he observes that it is more injurious than useful, since, if the plague be contagious, France is by no means protected against its admission, as it may be introduced into Paris by a traveller coming from England, or a bale of merchandise from Antwerp.—*Comptes Rendus*, Jan. 13th.

RUPTURE OF THE LIVER.

A BOY fell from a coal-waggon, and the wheels passed over his body. When seen by a medical practitioner, he was insensible, and there was paralysis of the lower extremities, depending on fracture of the lumbar vertebræ, and laceration of the spinal cord. The urine and fæces had been passed involuntarily. Death took place in five hours. The most remarkable feature in the case was the entire absence of any mark of *external injury* in the region of the abdomen, which was, however, tumid. On opening the cavity a large quantity of blood escaped, and when this was removed it was discovered that the liver had been ruptured transversely throughout its whole

extent. It was completely divided, and as cleanly as if it had been cut with a knife. The hæmorrhage had evidently proceeded from the portal vessels.—(*Mr. Kingdom: Lancet*, March 22.)

[This is an interesting case, illustrating forcibly the view entertained by Chaussier, that in violence to the soft parietes of the abdomen there may be extensive internal mischief without any corresponding indication of violence externally. The reporter of the case states that there was "*not the least mark on the skin.*"—*ED. GAZ.*]

PTHISIS IN CETACEA.

M. L. Bénard, of Caen, on examining the carcass of a female porpoise cast ashore on the Coast of Brittany, found the left lung almost entirely filled with tubercles,—to such an extent that the pulmonary texture had in a great measure disappeared. There existed at the same time numerous firm pleuritic adhesions of the same side. The opposite lung was sound, and there was no trace of tubercle in any other organ. The adipose tissue was generally scanty, and of a yellowish tint. This fact, observes M. Bénard, is curious, as indicating that tuberculous masses are formed of concentric layers, which may be easily detached the one from the other. The different constitution of the skin of those animals living in a dissimilar medium from that of man, suggests various reflections as to how far disturbed cutaneous function is concerned in the etiology of pulmonary tubercles. — *Revue Médicale*, Jan. 1845.

COAL AS FUEL.

ACCORDING to Mr. Bernan, the first legal notice which we have of this useful article being employed as fuel in this country, occurs about the end of the twelfth century. In the chartulary of Newbottle, there is a grant, in 1109, to the monks, by De Quincey, Constable of Scotland, of the coal between Whiteside and Pinkie. In 1239, Henry III. granted a charter to the inhabitants of Newcastle, to dig for coal, which is the first legal mention of the fuel in England.

PREVENTION OF MILK ABSCESS.

To the Editor of the Medical Gazette.

SIR,

I MUST beg to complain of a communication from Mr. J. Paterson, of Glasgow, in your last No. He gives a quotation from Dr. Marshall Hall's "Practical Observations and Suggestions," enjoining the application of the newly-born infant to the breast with

promptitude and perseverance, as a means of ensuring safety from milk abscess. Mr. Paterson claims the plan as his own; and refers to a paper of his in the *Lancet*, May 18, 1844. On referring to the said paper, I find that it does not contain a single word, or any reference, direct or remote, to the subject treated of by Dr. Marshall Hall. I am therefore at a loss to understand why Mr. Paterson should have felt occasion to address you on the subject. Trusting to your candour to insert these few remarks,

I am, sir,

Your obedient servant,

CRITO.

March 27, 1845.

TO CORRESPONDENTS.

Mr. J. P. Garlick, of Leeds, Dr. Cooper, and Mr. Sleight, will perceive that the subject to which their letters refer is noticed in our leading article.

Prof. Gregory's communication, On a New Method of procuring Phosphoric Acid, will be inserted next week.

Dr. Kingston's request shall be attended to.

We shall be obliged to Dr. J. W. Griffith if he will forward us the papers to which he refers.

There is some truth in "Crito's" strictures on the antiquated cases.

The signatures are required to the Proceedings of the Hereford Medical Association.

Dr. Ritchie's first paper on the Ovary, &c. shall have early insertion. We should like to receive the other papers in continuation.

"An Occasional Contributor and Constant Reader," under the present bill can only register as "surgeon." Being a graduate of the University of Leipzig, he possesses no legal title to practise as a "physician" in England, and cannot, therefore, be registered as such. We would advise him to wait until the bill becomes law. If he can satisfy any of the Colleges of Physicians that his diploma has been obtained *bonâ fide*, by residence and examination, we do not think he will experience any difficulty in acquiring a legal right to register as a physician without undergoing an additional examination. See the latter part of the 16th clause.

Communications have been received from M.D., Mediator, Omicron, Dr. T. Mayo, Dr. Ritchie, Mr. R. H. Meade, of Bradford, Mr. Dermott, Mr. Benton, Mr. H. Lee, and Mr. G. B. Childs.

APOTHECARIES' HALL.

Gentlemen who have obtained Certificates, March 27.—J. Brown, Bridgenorth, Salop.—W. H. Benson, Whitehaven, Cumberland.—S. G. Downing, Congleton, Cheshire.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

List of Gentlemen admitted Members, March 28.—A. J. Vandenberg.—R. Bryden.—P. Hudson.—E. C. De Crespigny.—J. G. L. Marsh.—H. T. Lomax.—J. E. Taylor.—J. Foster.—J. Moore.—J. H. Gandy.—J. Atterbury.

MORTALITY OF THE METROPOLIS.

Deaths from all causes registered in the week ending Saturday, March 22.

ALL CAUSES 1197

THE LONDON MEDICAL GAZETTE,

BEING A
WEEKLY JOURNAL

OF

Medicine and the Collateral Sciences.

FRIDAY, APRIL 11, 1845.

DR. HARE ON LIEBIG AND HIS CHEMISTRY.

IN a recently published letter, one of the admirers of Liebig has described him to be in chemistry "what Newton and Laplace were in astronomy and mathematics!" He is also said to be not so much an expounder of chemistry, or an operator in chemistry, as *Chemistry* itself! There are always two sides to every question; and as we have now been accustomed for a very long time to hear nothing but the most fulsome adulation of Liebig, even from men who ought to boast of being countrymen of a Davy and a Faraday, we only think it fair to quote the sentiments of one whose views are not likely to be biassed on the subject. We extract the following remarks, which, in our judgment, give a fair exposition of Liebig and some of his doctrines, from an introductory lecture delivered by Dr. Hare, Professor of Chemistry in the University of Pennsylvania. We believe that the lecture itself has had only a limited circulation in this country, although it deserves to be extensively read.—ED. GAZ.

In these, *i. e.* his [Liebig] physiological speculations, I conceive he has in various instances been bold, hasty, inconsiderate, and inaccurate*, but still, has advanced many ingenious ideas which are likely to be highly serviceable to physiological chemistry. He has quite as much merit in holding up ideas, before existing, in a new and popular form, as in suggesting such as are altogether original. Yet I would liken him to a military leader, who, after marching through a country, with drums beating and colours flying, should have his trumpets loudly sounded, as if a complete conquest had been effected;

* For what I consider as a palpable instance of an inversion of the truth, I refer to my "Pamphlet on the salt radical theory," page 21. Also Silliman's Journal, vol. xlv., page 259, Oct. 1843.

while leaving behind him many fortresses, of which the knowledge had prevented more cautious and considerate leaders from having previously undertaken the same expedition. Nevertheless, the philosopher of Giessen has excited a degree of attention in the great mass of physicians and agriculturalists which had never been gained had he neither deluded himself, nor the readers of his essays, with the prospect of an elucidation of the mysteries of animal and vegetable physiology, which it is beyond the present state of chemistry to afford. Moreover, the popularity which he has thus gained may lead others in the same path, who may rectify his errors, and remedy some of his omissions, without impairing what is really true in his doctrines.

There can be no better exemplification of the errors to which Liebig is addicted than his adoption of the following maxim:—"*There are many ways to the highest pinnacle of a mountain, but those only can hope to reach it who keep the summit constantly in view.*" It must be evident to every person of any experience in ascending mountains that although it may be necessary to keep the bearing of the summit in mind, our eyes must be upon the path; and that in most cases the safest and easiest mode of access causes the summit to be concealed for a time. A person who should implicitly follow Liebig's advice would probably fall over some precipice, or tumble into some fissure which might escape notice while keeping the summit of the mountain *constantly* in view. Is not the fallacious rule of action above quoted a good figurative illustration of a theorist, who, keeping his mind too much upon some hypothetical acme, overlooks insurmountable objections which a close attention to facts would make evident? Has not Liebig exemplified his own course?

Some of the excellent practical suggestions with respect to agriculture which are to be found in Liebig's work, are not the less worthy of being tried in practice because

they owe their origin to Sir Humphry Davy. I allude to the necessity of attending to the chemical constitution of soils and manures, so that one may be of a nature to correct the defects of the other. All that Liebig alleges of the reagency of gypsum, of ammonia, bone, earth, urine, carbonic acid, and of the alkalis, seems to me well worthy of attention, though partially inconsistent with the experimental inferences of Dr. Jackson, a distinguished American chemist*.

Ordinary fires being supported by the union of atmospheric oxygen with the charcoal and the hydrogen of fuel, while the respiration of animals is attended by a union between atmospheric oxygen and the carbon of the blood, it has long been apparent that a large consumption of oxygen must be thus necessarily occurring. On the other hand, the observation, that from the leaves of vegetables exposed in water to the solar rays, a copious emission of oxygen ensued, and the fact that carbon was found largely to enter into their composition, led very naturally to the inference that animals inspire oxygen, and give out carbon; while vegetables, respiring the gaseous compound formed with carbon by oxygen, called carbonic acid gas, emit oxygen, retaining the carbon.

But some contradictory observations had caused this view of the subject to be represented as incorrect; and the question has always been undecided. Liebig has, with great ability, taken that side of this question, to which I have always adhered†. He considers that the carbon in vegetables is due to the absorption of carbonic acid, and infers that it is thus that the enormous consumption of oxygen by fires and animal respiration is compensated. He shows by calculation that, agreeably to analysis, there are three thousand millions of millions of pounds of carbon in the air in the state of

carbonic acid, and infers that the carbon in all the mineral coal known, bears but a small proportion to that thus existing in the aeriform state.

It is known that inland plants yield by incineration, potassa, the active matter of common soap ley. Plants on the borders of the ocean yield soda, an analogous substance. In various species of grain certain salts are found to exist always in a certain ratio. Now, however minute are the proportions of these substances, Liebig correctly avers, as I believe, that their absence incapacitates a soil for the successful cultivation of the kind of plant requiring them.

This distinguished chemist concurs with the celebrated Davy in representing plants as taking up all soluble matters presented to their roots in a sufficiently diluted state, but appears to be peculiar in the opinion that it is only that portion of carbon which is in the state of gaseous carbonic acid which forms their food.

According to Davy, Berzelius, and others, vegetable matter, constituting humus or *geine*, yields certain acids, which, being absorbed, are the means of nutrition. But both Davy and Liebig, the latter especially, consider that carbonic acid is imbibed by the vegetable foliage, the carbon being assimilated and the oxygen exhaled. Of course water is all-important, and appears to be received through the leaves as well as the roots.

Lignin, which constitutes the fibres of wood, hemp, flax, and those of plants in general, also sugars, gum, starch, and other analogous vegetable products, consist merely of water and carbon. Nitrogen exists in plants in comparatively small proportion; yet its presence appears to be of primary importance, since it has a sort of ubiquity in the organs and juices. But although this element forms nearly four-fifths of the atmosphere, it seems to be generally conceded, and is by Liebig urged, that it is not directly obtained from that source by vegetation. According to this philosopher, a previous conversion into ammonia, by a union with hydrogen, is requisite; this alkali, and the carbonic acid with which it unites, when exposed to the atmosphere, being mainly the food of plants. But though nitrogen pervades vegetable organization, it abounds in a larger proportion in that of animals: hence it has been a question how animals, *feeding on vegetables only*, are supplied with a sufficiency of nitrogen. It naturally occurred, in the case of vegetables, that they might derive it from the atmosphere during respiration; but experimental investigation has shown that there is no absorption of nitrogen during that process tending to justify this inference.

Thus, in the supply of nitrogen to the vegetable and animal kingdom, Nature, from

* Doctor Jackson is of opinion, that the ammoniacal salts act in a different way from that stated by Liebig—that the carbonate of ammonia acts upon the organic matters of the soil, and renders the organic acids neutral and soluble—decomposes and renders inert noxious metallic salts and other compounds.

Dr. Jackson objects that Liebig has not produced any instance where a plant has been raised by a solution or other preparation of ammonia in a purely silicious or other pure earthy soil. This question is, therefore, open for research, and experiments have been instituted to decide it. (That ammonia, in the state of carbonate, or in solution in water, has a great effect in stimulating plants, has long been known to gardeners; but they also know that the plant so treated soon perishes. It would seem to be an analogous case to that of plants stimulated by chlorine, but not supplied with a proportionally increased allowance of food).—Webster's edition of Liebig's Organic Chemistry, p. 411.

† This side of the question has been experimentally supported by Professor Daubeny, of Oxford, England.

considerations which are inscrutable to human reason, prefers an indirect and precarious source to one which is superabundant and always at hand. Nor is this the only instance. Fishes, which swim in an element consisting of eight parts in nine of oxygen, are dependent for this principle on the contact of their gills with a minute portion of air absorbed from the atmosphere.

But Liebig alleges that, as a large portion of vegetable diet merely serves to yield the carbon required for respiration, there is, in the residue, a due proportion of nitrogen forming flesh and blood; since it has been shown by recent analyses that in beans, wheat, and other grain, there are substances capable of isolation which are identical in composition with the fibrous matter of the blood or fibrin, and with serum or white of egg, called albumen, also with milk curd or casein. Thus animals find ready formed in some parts of vegetables, if not in all, the ingredients of their flesh and blood. But some of the most abundant articles of vegetable food, such as sugar, starch, gum, fat, oil, &c., being devoid of nitrogen, cannot alone contribute to the formation of flesh. They go, says Liebig, to support the fire in the lungs, where thirteen ounces and a half of carbon are, on an average, daily consumed by a man, causing as much heat as would raise three hundred and seventy pounds of water to the temperature of the blood.

It is alleged by the same author that all the oxygen, thus combined with carbon, is in the first instance taken up by the protoxide of iron in the venous blood, which, being consequently changed in colour, causes the reddening of the blood ere it passes into the arteries. To this it has been objected that the quantity of iron in the blood is inadequate to take up a sufficiency of oxygen; and it appears to me that were the fact to be as suggested, the heat would be evolved in the lungs, where the absorption of oxygen takes place; not in the capillaries, where it is transferred to carbon.

Moreover, I am of opinion that, as protoxide of iron is of a more dingy red than arterial blood, it would be incompetent to colour this liquid, as alleged, unless assisted by some other agent, such, for instance, as sulpho-cyanhydric acid, which has been heretofore represented as participating in the result.

It would seem, on the whole, that Liebig has, in this respect, contributed more to *enforce* than to *alter* the opinions offered by me on this subject in the former editions of my text-book. Yet I have always thought that a machinery so complicated as that employed in the process of respiration could not have been devised merely for the generation of animal heat or the oxidisement of

carbon in the tissues, as Liebig seems to believe. It has struck me that the necessity of atmospheric oxygen to fishes would hardly be ascribed satisfactorily to the ponderable matter thus received through their gills, or any heat which it may produce. I have suspected that there was some imponderable fluid, supplied to the nervous system by the process in question, to which the classes of animals, enjoying the benefits of it extensively, are indebted for the superiority over those which do not enjoy that advantage to a similar extent.

One of the greatest services rendered by the author whose opinions are under consideration, is, as I think, in directing attention to the different offices performed by two classes of vegetable products which may be distinguished as nitrogenised and as devoid of nitrogen. All the various species of sugar, starch, gum, or mucilage, oil, fat, and gelatine, are represented as having a tendency rather to go to the support of the respiratory process, or to produce obesity; while the fibrin and albumen of flesh and blood are sustained by those portions of animal and vegetable food which contain nitrogen in nearly the same proportion as it exists in them. The greater vigour of a horse when fed on oats or maize is in this way explained, by the greater proportion of matter contained in such grain, which is of a nature to compensate the wear of the muscles.

Highly worthy of consideration, also, are Liebig's suggestions respecting the services rendered by theine, a peculiarly highly nitrogenised principle, common both to tea and coffee. Liebig ingeniously shows that this principle requires only an addition of water and oxygen in order to convert it into taurine, an active principle of the bile. The extensive use of tea and coffee by civilised nations thus appears to have been the result of a sort of instinctive empirical research, leading to beneficial results, which physicians were heretofore unable to appreciate or explain. In fact, as food, coffee and tea were heretofore considered as almost valueless; but now it appears that they serve to furnish nitrogen in a more concentrated form to those whose indolent habits might be incompatible with the consumption of sufficient quantity of ordinary nutriment to obtain a requisite quantity of that element.

There is nothing which seems more completely impenetrable to the human mind than the power of vitality. Probably in no instance is this power better exemplified than in the changes which, by means of the vital spark, take place in seeds and eggs. In the latter, especially, the principle of life seems to hold in check those chemical affinities which, so soon as it is extinct, convert into a putrid mass that which, life enduring, would be

transformed into a young bird. The vital power of animal and vegetable organisation not only counteracts the conflicting affinities of inorganic atoms: it also endows groups, constituted of little else than three or four of those atoms, with powers analogous to those inherent in simple elementary atoms, and thus extends immeasurably the bounds of useful chemical reaction.

I infer that the organs of animals and vegetables have two modes of effecting the object for which they were created. In one mode, in which chemical reaction would fail to accomplish the requisite transformations, being such as affect masses rather than their component atoms, the organs react directly, in a mode entirely hidden from our view. There is, as Liebig justly alleges of such phenomena, an invisible cause. In the other mode, creating such chemical compounds as are suitable for their purposes, it may more or less leave to these the issue.

Liebig asserts "that we shall obtain that which is obtainable in a rational inquiry into nature, if we separate the actions belonging to chemical powers from those which are subordinate to other influences;" but the learned author does not show us how we may accomplish this separation; and probably for the best possible reason, that, great as are undoubtedly his skill and his genius, he is incompetent to effect any such separation. He seems to forget that he elsewhere admits "chemical powers to be subordinate to other influences, whether of life, of heat, or electricity." To me it seems, that to separate the action of these powers from such as are subordinate to other influences, would involve their separation from themselves; and that it were inconsistent to suppose that chemical agents, which are created by the vital power, cannot be also modified by it so long as it prevails.

"But," says this distinguished author, "the expression vital principle must, meanwhile, be considered as equivalent to the terms 'specific' and 'dynamic' in medicine. *Everything is specific which we cannot explain, while, by the epithet dynamic, everything is explained which we do not understand.*"

This disparaging language, as respects the power of life, seems not to be quite consistent with the following opinions elsewhere stated by the celebrated author.

Our notion of life involves something more than merely reproduction—namely, the idea of an active power, exercised by virtue of a definite form and production, and generation in a definite form. By chemical agency we can elaborate the constituents of muscular fibre, skin, and hair, but by such means are enabled to create no organised tissue, no organic cell. The production of

organs, the co-operation of a system of organs, and their power not only to produce their component parts from the food presented to them, but to regenerate themselves, in their original form and endowed with all their properties, are characters belonging exclusively to organic life, and constitute a form of reproduction independent of chemical powers. The chemical forces are subject to the invisible cause by which this form is produced, and of the existence of which we are made aware only by the phenomena which it induces. Its laws must be investigated just as we investigate those of other powers which produce motion and changes in matter. The chemical forces are subordinate to this cause of life, just as they are to electricity, heat, and mechanical force. Such is the influence, and no other, exercised by the vital principle over chemical forces."

Thus the author, notwithstanding his contemptuous allusion to the vital principle, and his confounding it in value with words alleged by him to be insignificant, in the passage last quoted, justly ascribes to the principle in question a prodigious efficacy.

In the following passage Liebig's mode of reasoning is exemplified:—"Is it truly vitality which generates sugar in the germ for the nutrition of young plants, or which gives to the stomach the power to dissolve and prepare for assimilation all the matter introduced into it? A decoction of malt possesses as little power to reproduce itself as the stomach of a dead calf; both are unquestionably destitute of life, but when amylin or starch is introduced into a decoction of malt, it changes first into a gummy-like matter, and lastly into sugar. Hard boiled albumen, and muscular fibre, can be dissolved in a decoction of a calf's stomach, to which a few drops of muriatic acid have been added, precisely as in the stomach itself. The power, therefore, to effect transformation does not belong to the vital principle. Each transformation is owing to a disturbance in the attraction of the elements of a compound, and is, consequently, a purely chemical process."

But is there any truth in the allegation that in no other than a chemical process can there be any disturbance in the attraction of the elements of a compound? Is it by a chemical action that an electrical current subverts chemical affinities? Is it by a chemical action that vitality endows chemical compounds with peculiar attractive powers? Has not Liebig sanctioned the opposite idea in the passages which I have cited?

HÆMORRHAGE FROM STOMACH, AND DEATH, FROM SWALLOWING A COPPER COIN.

To the Editor of the Medical Gazette.

SIR,

If you think the accompanying case worthy a place in your valuable journal, I shall feel obliged by your inserting it.—I am, sir,

Your obedient servant,

PERRY DICKEN, M.R.C.S.

Ashby-de-la-Zouch,
Leicestershire.

A. B., a boy 10 years of age, was amusing himself by throwing some half-pence into the air and catching them in his mouth, when one of them accidentally slipped into the œsophagus and was swallowed. Considerable effort was made to dislodge it, but without avail, and it passed into the stomach. This took place on the 16th of January, 1845. A medical man in the neighbourhood was immediately sent for, but from the very slight disturbance it produced, it seemed at first very doubtful whether the halfpenny had been swallowed or not. Purgatives of an oleaginous character were exhibited for several days, in order to dislodge it from the stomach, but no appearance of the coin was observed in the secretions from the bowels. He continued his usual occupations, and attending his school duties as before, occasionally, however, complaining "of a sense of weight and uneasiness in the epigastric region, and rather towards the right side, and sense of distension after meals," which, however, generally subsided in the course of three or four hours. He continued much in the same state until the night of the 12th February, when, after being in bed a short time, he was suddenly seized with sickness, and instantly vomited a large quantity (more than a quart) of fluid arterial blood. The hæmorrhage continued at intervals through the night, but was checked by giving large doses of tartrate of antimony, which considerably depressed the action of the heart. On the next day (the 13th) the bleeding again recurred to a great extent, and after throwing up a considerable quantity of dark fluid, he became sensible (as he described it at the time) "of something passing the stomach,

and thence into the bowels." A temporary relief was obtained, and sanguine hopes were entertained that the mischief was arrested, but the hæmorrhage again recurred, and he suddenly sank on the evening of the 14th, in a state of complete collapse.

Examination thirty-six hours after death.—Body presented externally a complete state of paleness from draining of blood. On opening the stomach a circular ulceration of the mucous surface was observed, corresponding exactly in size to the halfpenny, but at a considerable distance from the pyloric orifice. The surrounding coats of the stomach did not exhibit any unusual vascular appearance, nor were any traces of inflammatory action observable in any other part of the organ. The coin had evidently escaped through the pylorus. On tracing carefully the track of the whole alimentary canal from the duodenum to rectum, the halfpenny was discovered at the very termination of the colon, lying loose, and easily removable; in fact, its situation was such that it would in all probability have been voided by the next evacuation from the bowels. Not the slightest alteration of structure, or any abrasion of any other part of the mucous surface of the alimentary canal, existed, or any other morbid appearance.

REMARKS.—There are, I think, in this case, some circumstances worthy of notice. 1. As to the length of time which had elapsed from the swallowing the coin to its passing through the pylorus. 2. As to the hæmorrhage. 3. As to the effect produced upon the vital organ by its presence. 4. As to the treatment pursued.

It will be seen on a review of the case before us that a period of nearly a month had elapsed from the coin being first swallowed to any material disturbance having taken place; during the whole of which time little was complained of, excepting a sense of occasional uneasiness in the region of the stomach, generally, however, much increased for three or four hours after taking food; his spirits were good, and appetite as usual, up to the day when he was seized with more alarming symptoms. The pain appeared to be more from "mechanical weight" than from any other disturbance produced

by its presence in the system. I should be much disposed to think that the coin was in some way spasmodically retained by the muscular contraction of the stomach, for the ulcerated surface was at a considerable distance from the pyloric orifice, and I can see no explainable reason why this foreign substance should not have passed into the bowels, and so have been voided *per vias naturales*.

As respects the hæmorrhage, I am I own still at a loss to account for such an amount of blood as was poured out in the three days preceding his death; and, had it not been for a post-mortem examination of the body, I should have been in great doubt as to whether the hæmorrhage was caused by the presence of the "foreign body" in the stomach, or to some other accidental circumstance: there can be little doubt, however, that in some way the action of the coin was immediately connected with the rupture of some vessel, and that its detachment from the situation in which it was lodged, and its passage through the pylorus, evidently led us to such a conclusion. The time when the halfpenny became detached, and was changing its situation, was forcibly described by the little patient (who was an extremely intelligent boy); and he expressed himself as immediately relieved after its passage.

As to the fatal termination of the case. This appears to me to be also a matter of speculation. Abstractedly considered, I cannot see any positive reason why a substance like the one swallowed should have been the immediate cause of death. Many cases are on record of buttons and other analogous substances being frequently swallowed by accident, but I am not aware of any case of a precisely similar nature to the foregoing being mentioned, although I doubt not many such have occurred. At first some apprehension was felt lest any poisonous influence from the action of the copper on the system might be felt, but there did not appear to be the slightest foundation for such an idea; indeed, the halfpenny, when taken from the body, exhibited not the slightest alteration in appearance, and the letters on the coin, &c. were perfectly visible.

Lastly, as respects the treatment. The first object appeared to be (supposing the coin had been actually

swallowed) to endeavour to dislodge it from the stomach, and to pass it through the intestinal canal: this purpose was attempted by giving purgatives of castor oil, common oil, &c., but as there was no appearance indicative of its passage after a few days, and the symptoms not appearing to demand a continuance of medicine, all treatment was suspended, and, until the hæmorrhage occurred on the night of the 12th February, nothing active was resorted to. The chief indication then appeared to be to arrest the bleeding, which, by the treatment pursued, was considered probable would be the case. The recurrence, however, of the discharge, accompanied with the suppression of vital powers, appeared to be more than the system could bear up against, and he rapidly sunk from a complete state of exhaustion.

I leave it to any of your readers to say whether they could suggest any plan in a similar case where any treatment could be of service in discharging the substance swallowed.

SOME OBSERVATIONS
ON THE
MEDICAL TOPOGRAPHY, CLIMATE,
AND DISEASES,
OF THE
BIGHTS OF BENIN AND BIAFRA,

WEST COAST OF AFRICA.

BY W. F. DANIELL,
Member of the Royal College of Surgeons of
England, &c.

[Continued from p. 709.]

The Bight of Biafra.

THE Bight of Biafra, known by the early English writers on Africa as the Ethiopic Gulf, commences at Cape Formosa, and embraces the whole of the coast between it and Cape Lopez, situated in Lat. $36^{\circ} 10' S.$ and $8^{\circ} 40' E.$ Long. In physical appearance it varies but little from the usual cheerless prospect of the alluvial lowlands which here, as in other regions, are densely covered by impervious mangrove forests. A limited tract of land near the equator is, however, of a more elevated character, and includes the mountainous districts of Qua, Rumby, and Camaroons, which, with the adjacent islands of Fernando Po, Princes, and St. Thomas, are of volcanic formation. The rivers in this are more nu-

merous and of greater size than in the preceding Bight; they generally derive their origin from the upper belt of table lands of the interior. The largest of them are much resorted to by European vessels of considerable tonnage, which export from the more fertile and cultivated inland countries immense quantities of palm oil, with ivory, and other mercantile productions. The legitimate commerce that has recently sprung up since the suppression of the slave trade is one now annually increasing in importance, and will eventually become extremely lucrative and valuable to the commercial interests of Great Britain.

The ardent love of adventure which stimulated the Portuguese to send forth those enterprising expeditions for the discovery of unknown empires in all quarters of the globe, seems to have been conspicuously directed, towards the middle and close of the 15th century, to the east and west coasts of Africa. A reference to the history of those periods will furnish us with the records of several expeditions exclusively undertaken with the view of exploring this and the other divisions of Western Africa, then described as North and South Guinea. Even at such an early date as 1459, a very curious map, constructed by a Venetian named Fra Mauro Canaldolese, professes not only to delineate the shores of these Bights, but also the probable southern termination of the African continent, although the Cape of Good Hope was not discovered by Bartolomew Diaz till 1486, who then termed it "Cabo de todas los tormentos*." Time since then has proved very unpropitious to the supremacy of the first discoverers of these countries, since only two of their original colonial possessions in the Bight of Biafra, the islands of Princes and St. Thomas, now remain attached to the crown of Portugal.

The Rio Nun, familiarly termed Brass River by the Europeans in the Bights, is also recognised by its native appellation of Quorra, or Kowara. It is situated eight miles from the Sengana, and is the first stream that engages the attention of the voyager. The entrance, near two-thirds of a mile in breadth, can only be discerned at short distances from seaward in consequence of the flat and marshy aspect of the

land in its immediate vicinage. The western point of the shore, at its junction with the ocean, has received the title of Cape Nun, and the other, or opposite one, that of Cape Filana. This river resembles most of the others in the Delta, in the dreary and monotonous features of the landscape, which are those calculated to inspire anything but a favourable impression as to either its scenery or salubrity. On both sides, for a brief space, a narrow beach of sand skirts the forest jungle, and is superseded by accumulating banks of vegetable and alluvial detritus, enveloped by numberless mangrove bushes that project to a greater or less extent beyond the water's edge. A few miles from the bar on the left shore, partially intermingled with cocoa-nut palm and plantain trees, is Pilot's Town, or Cassah; while, deeper inland within the woods, is another village containing about an equal number of mud-huts of the most wretched construction. It can only be approached by intricate by-paths, and is also entitled Cassah, or Acassah. On the eastern bank, nine or ten miles from Cape Filana, is a creek which connects this river with the St. Bento, and through which the slave-factors transmit their prohibited cargoes when the river is blockaded by any armed vessel. This creek likewise leads, by means of divergent branches, to the town of Brass, and is the ordinary route taken by the fishing canoes when passing from one river to the other. Eboe, or Ibue, the long Eboe of the Bonnians, is 120 miles inland, and the confluence of the Tchadda with this river, and the Felatah town of Rabbah, are respectively 152 and 313 miles to the northward of Eboe. The inhabitants of the Brass towns, similar to other people of Eboe derivation, are addicted to those barbarous fetish rites and superstitious beliefs that characterise the nations of the adjoining rivers in communication with them. These ceremonies, through the ministry of their Jujunen, or priests, they render subservient to the treatment of the painful maladies to which they are liable. The most prevalent are confined to the cutaneous tissues, and these, with morbid affections of the abdominal viscera, comprise the greater proportion of the endemic diseases of these habitable morasses. In the countries bordering the superior course of this stream,

* Cape of all torments.

Mr. Oldfield remarks that the diseases which came under his observation were "large ulcers from the bites of mosquitoes, diarrhœa, dysentery, variola, ophthalmia, and cataract; the further we advanced into the interior, the more common we found cataract; at Rabbah I saw several hundred cases of double cataract; most of the natives were willing to undergo the operation; as we were not making a sufficient stay, it was not attempted.—The natives of Rabbah, and the neighbouring towns and villages high up the river, more especially where Mahomedanism prevails, are very cleanly in their habits, performing their ablutions twice a day: there were very few cases of cutaneous diseases among them."* Of the indigenous products exported from this river, palm oil is the one alone estimated as worthy of the notice of the white trader. Some ivory, pepper, and dyewoods, may be occasionally obtained, but not in such quantities as to bring a sufficient remuneration for the outlay and trouble taken in procuring them. The sand bar at the mouth of the river has only two fathoms of water on it at full tides, and is therefore an obstacle to any vessel above a certain burthen. The oil carried away by the few which now frequent it seldom amounts to more than six or seven hundred tons during the year, inasmuch as the Eboe traders manage to monopolize nearly the whole produce of the inland districts to send to the Calabar and Bonny markets. This stream, though not so unhealthy as the Rio Formosa, is nevertheless one eminently deleterious to the unacclimated European. The mortality among the crews of the shipping averages at least from twenty-five to fifty per cent.

It would not come within the object of these papers to enter into any descriptive outline of the topography and natives of the many inland kingdoms that are scattered upon the banks of this river, but it may perhaps be requisite in a medical point of view to cast a retrospective glance on those naval expeditions that have been undertaken for the development of their commercial capabilities and resources. Centuries upon centuries have elapsed since this river, known as the Niger of

the ancients, first became the subject of manifold interesting and profound controversies. Herodotus, Strabo, Ptolemy, Abulfeda, Edrisi, with Leo Africanus, and a host of more modern writers, have vainly essayed to dispel the mysterious gloom in which its origin and termination were enshrouded. The number of hypothetical treatises and dissertations, the memorials of successive ages, would alone suffice to demonstrate that these points constituted a geographical problem the most difficult of solution. The exploratory researches, however, of Park, Clapperton, and the Landers, in 1831, have at length partly set at rest this famous and long disputed question.

No sooner had the discovery of the Landers been promulgated that the Rio Nun was the chief outlet of this river, and its ascent was practicable by vessels of moderate tonnage, than an expedition was immediately fitted out at Liverpool with the intention of testing how far the experiment might succeed. It consisted of two steamers, the Quorra and Alburkah, with the Columbine brig tender. These vessels crossed the bar on the 19th of October, 1832, and progressed some distance into the interior before the endemic agencies manifested their morbid effects, which commenced from the twenty-third day after their ingress. Pursuing their mercantile avocations with but indifferent success at the various country markets throughout the years 1833-34, and after penetrating as far as Rabbah on the Quorra, and Fundah on the Tchadda, it was finally abandoned, having proved a complete failure. Out of forty-eight white persons composing their complement of Europeans, only four survived the pestilent sickness of the country; among these were McGregor Laird, Esq., Capt. W. Allen, R.N., and Mr. Oldfield, one of the medical officers; the other, Dr. Briggs, having unhappily fallen a sacrifice to his arduous exertions. To one of the talented projectors of this enterprise, and Mr. Oldfield, we are indebted for the history of the primary effort to establish a commercial intercourse with central Africa by means of the navigation of the Quorra. The predominant maladies which conspired to create the great mortality on board were dysentery and those adynamic remittent

* London Medical and Surgical Journal, Vol. viii. p. 406.

fevers common to the other rivers of Western Africa. The Quorra steamer having been purchased by the West African Company, reascended this river in September 1835, and proceeded to the confluence of the Tshadda, under the charge of Mr. Becroft. During a sojourn of three months inland, two out of five men were cut off by the insalubrity of the clime, one of whom, a creole, of Antigua, had been long suffering from organic disease of the lungs. In 1840, the *Ethiope*, a steam vessel, expressly equipped for the coast of Africa, by Mr. Jamieson, of Liverpool, and also under the command of Mr. Becroft, after surveying the Rio Formosa and determining its sources, entered the Quorra by the anastomosing branch below Eboe, and explored the river as far as Lever, the highest point hitherto attained by any vessel. Out of twelve white individuals, the loss of life amounted to five, three men and two boys, which, considering the lengthened period of six months, may be deemed as comparatively moderate, if contrasted with the mortalities of the other expeditions. The germs of the disease and their subsequent development are solely to be ascribed to their protracted exploration of the humid regions of Benin. The last and most unfortunate expedition, the disastrous result of which will remain fresh in the memory of most, was sent forth under the auspices of the British Government in 1841, on a scale of proportionate magnitude and liberality, with the view of forming a series of treaties with the native chiefs for the suppression of slavery. Three steamers, the *Albert*, *Soudan*, and *Wilberforce*, with the *Amelia* tender, composing this armament, passed the bar on the 13th and 15th August, and after a very injudicious delay of several days at its entrance, steamed up the river. The remittent and other fevers of the country began to display themselves from the 4th September, and continued from that date to gradually affect the majority of their European crews. These diseases still maintaining their alarming ravages, and even appearing rapidly to gain ground, it was ultimately thought advisable to transmit the *Wilberforce* and *Soudan* through the Delta into the ocean with the sick, and the *Albert*, shortly after reaching Egga, was compelled to follow from the same

pestilential causes. During the trifling period of seven weeks, almost every white person on board was prostrated by sickness. Out of 145 Europeans, no less than 130 were attacked by disease, and 43 fell victims to fever, exclusive of casualties. The *Albert* lost on the whole 26, the *Soudan* 14, and the *Wilberforce* 13 men; total 53. Now as this expedition was avowedly conducted upon hygienic principles, it came of course under the criticisms of the medical practitioners resident in Africa, who from their intimate knowledge of the climate and diseases of these countries might be deemed as fully authorised to express their opinions upon these subjects. Accordingly, in the outset, the selection of the most unhealthy season for the commencement of their operations, with the inefficiency of the precautionary means adopted for the preservation of the health of their crews, rendered it an easy matter for them to predicate its unsuccessful issue. It was afterwards pointed out that in various instances the medical arrangements evidently betrayed but an imperfect acquaintance with the nature and effects of those endemic influences so fatally exemplified in the consequent sickness and mortality. The horror of malaria was carried out to such an excess as to keep in full play Dr. Reid's "ventilating and medicating apparatus," with which each vessel was supplied, forgetting that when the men emerged from the purified compartments below, they were exposed upon deck to the moist and tainted atmosphere of the swamps. In order to obviate this inconvenience it was stated in the general orders that "those who were obliged to be on deck on duty will be supplied when in unhealthy localities with respirators, and a fire is then to be kept all night in the cookhouse." Such prophylactic measures are, however, of little or no utility in the rivers of the Bights, and can only be placed on a par with the somewhat sapient plan, recommended in a work on the African colonies, of erecting a number of limekilns on the verge of the Bullom swamps, in order to decompose those miasmatic vapours that might emanate therefrom to the detriment of the opposite town of Sierra Leone.

[To be continued.]

SHORT ACCOUNT
OF A
CASE OF ENCYSTED EMPYEMA
OF TWELVE YEARS' STANDING.

By HENRY LEE, Esq.
(*For the Medical Gazette.*)

WILLIAM BARTLETT, æt. 59, died upon the 16th of March, 1845, having, for the last twelve years, been under the care of Mr. Goolden, of Maidenhead. Upon examining the body after death the following appearances presented themselves:—

The lower part of the right side of the chest was compressed, and from this point the upper part of the body was inclined towards the right side, presenting a similar appearance to that which would be produced by a lateral curvature of the spine. Between the anterior extremities of the fifth and sixth ribs, upon the same side, were two fistulous openings, with their edges inverted, and discharging a bloody fluid. The two layers of the right pleura were connected by numerous bands of adhesion. Between them, in the upper part of the chest, were contained about six ounces of transparent serum, while in the lower part a cavity presented itself, containing a dark gangrenous fluid, and circumscribed by extremely firm adhesions. This cavity was about six inches long, and four inches broad, and communicated freely with the exterior of the body by means of the sinuses above mentioned. The pleura, in this situation, was in some places three lines in thickness, and was lined upon its internal surface by a soft vascular layer, from which the bloody fluid in the cavity had apparently been secreted. The structure of the lung in contact with the diseased pleura was condensed to the depth of two or three lines only, but in other respects did not differ from the remainder of the pulmonary tissue. The lower surface of the right lung, and the upper surface of the right lobe of the liver, were firmly adherent to the diaphragm. The left lung presented soft adhesions over its whole surface. On both sides the lungs were greatly emphysematous, and their structure was everywhere loaded with serous effusion. In several situations small masses of calcareous matter presented themselves, but in no part could

any tubercular deposit be discovered. The pericardium was universally adherent. The heart was healthy, with the exception of the tricuspid valve, the aperture of which was dilated.

The history of this case was, that twelve years before his death he had been exposed to severe cold for two nights and three days, and immediately afterwards was attacked with inflammation of the right side.

In the course of a fortnight, an abscess burst, and discharged several pints of matter; and a fistulous communication remained in his side from that time to the period of his death. Considerable quantities of pus were at different times discharged, but it occasionally happened that the opening became nearly closed, and considerable oppression of the breathing would then be experienced until a free discharge of pus took place. When the external opening was larger than usual, a quantity of air would sometimes enter, and thus the patient could again expel at pleasure with considerable force. During a few weeks preceding his death, a very considerable quantity of blood was passed with the discharge from the side.

The preparation illustrating the principal points in this case is deposited in the museum of St. George's Hospital.

13, Dover Street, April 4, 1845.

ON THE PRESENCE OF PHOSPHATE
OF MAGNESIA IN BONE,

AND ON A NEW METHOD OF PROCURING
PHOSPHORIC ACID FROM BONE.

By PROFESSOR GREGORY.

To the Editor of the Medical Gazette.

Sir,

I HAVE just seen a notice, in your journal, of my *Outlines of Chemistry*; and I take the liberty of addressing you, not to complain of any part of that notice, which is only too flattering to my little work, but to mention that the supposed clerical error, in the method of preparing phosphoric acid from bones, is not an error, for that there is a very considerable quantity of magnesia present, that earth being a never-failing constituent of bones. I might, indeed, have stated this more precisely, but brevity was my object, and I con-

sidered the fact as quite well known, since every good analysis of bones mentions from 1.5 to 2 per cent. of phosphate of magnesia.

Although I take this opportunity of showing that the process described by me appears as it was intended to do, I should not have thought it necessary to address you on the subject, were it not that, in repeating the process for my lectures, I have found that part of it in which alcohol is used to separate the phosphate of magnesia not to answer. The reason of this I conceive to be, that, before the phosphate of magnesia can be separated by alcohol, the phosphoric acid must be in one of its modifications, probably in that called the tribasic or common phosphoric acid; and that my experiments were made with an acid wholly or partly in one of the other modifications. I have not yet been able to succeed with the alcohol; but in the course of my attempts I have been led to a much better method, which I shall now describe. Even were the process with alcohol more easily managed, still, in this country, alcohol can never be much used at its present price; so that any means of dispensing with its use are desirable.

Having removed the whole lime by means of sulphuric acid, and evaporated the filtered liquid (filtering again if any sulphate of lime separates during the evaporation) to the consistence of syrup, a few drops of sulphuric acid are added, to make sure that no lime remains. Of course, if turbidity ensues, the lime has not been completely separated before; and the addition of sulphuric acid, filtration after adding some water, and evaporation, must be repeated, till the syrupy liquid continues quite clear when sulphuric acid is added. This liquid now contains only the phosphoric acid, the magnesia, and the excess of sulphuric acid. It is concentrated and heated in a covered platinum crucible, until the whole of the sulphuric acid has been expelled, and the residue has acquired a low red heat. On cooling it forms a glass, perfectly colourless and transparent, which contains only phosphoric acid and the magnesia of the bones.

This glass, when boiled with water, dissolves rather slowly, but completely. When the solution is again concen-

trated in a capsule of platinum, until most of the water is expelled, and the temperature rises to between 595° and 600° F., it suddenly, while hot, becomes turbid from the separation of a peculiar phosphate of magnesia. At the same moment the phosphoric acid begins to crystallise like the granular sugar deposited in honey, a form ascribed by Peligot to the bibasic or pyro-phosphoric acid. If the same temperature be kept up for fifteen minutes (and we can ensure it without a thermometer by heating to that point, and no further, at which the acid begins to vaporise with the water in the open capsule), the whole of the magnesia separates in the form of a powder, which is quite insoluble in water or acids. When cold, the mass is digested with water, which dissolves the phosphoric acid, leaving the phosphate of magnesia as a heavy, fine, snow-white powder, of a faint silky lustre. *The filtered liquid is free from every trace of magnesia*, and may be considered as pure phosphoric acid. Of course, however, if the bones contained chloride of sodium, a trace of phosphate of soda would remain. In that case the burnt and powdered bones ought to be boiled with water, to remove any soluble chloride. But I have not hitherto found it necessary to do this.

The above simple process puts it in our power to obtain pure phosphoric acid from bones cheaply and in any quantity. There is no difficulty in the execution of it; it is only necessary to keep up the heat of about 600° for twelve or fifteen minutes, but not to go beyond that temperature, because a stronger heat would again, no doubt, produce the glass formed in the first fusion, which, as we have seen, is entirely soluble in water. The acid is easily tested for magnesia by diluting and supersaturating with ammonia*, when, if magnesia be present, it very soon appears as ammoniaco-magnesian phosphate. In six or eight different operations I found no trace of a precipitate even after several days; but if I added a trace of magnesia, it was at once detected. In fact, I did not fail once (after the first operation, in which I had not heated long enough, from not knowing the nature of the salt

* Dilution is necessary, for otherwise phosphate of ammonia falls as a crystalline powder.

formed) in obtaining an acid absolutely pure as far as concerned magnesia.

The phosphate of magnesia, thus separated, is a peculiar and anomalous salt. I have made six analyses of portions made in the six different operations mentioned above, and they all agree closely with the formula

that is, an acid sesquiphosphate of magnesia, according to the older notions of phosphoric acid. This composition cannot be reconciled with any of the three generally admitted modifications of phosphoric acid; and it would seem to indicate, either that another modification exists, or that the theory of phosphoric acid and the phosphates, at present admitted, is erroneous. I am at present occupied in examining this point; but the salt itself is so insoluble in water and acids, that I have been unable to ascertain in what modification the acid exists in it: whether, namely, it contain common or tribasic, pyro-, or bibasic, meta- or monobasic phosphoric acid, or some new form of phosphoric acid. The acid filtered from it, when neutralised by ammonia, gives a white precipitate with nitrate of silver, which excludes common phosphoric acid, as might be expected at the temperature. But the acid in the magnesia salt is not necessarily the same as the free acid in which the salt is formed. As I have said above, the insolubility of the salt is a great obstacle to ascertaining this point, although by other means I hope to attain the object. That insolubility is so great, that I may almost rank the new phosphate of magnesia along with sulphate of baryta. Boiling nitric acid, hydrochloric acid, and aqua regia, are almost entirely without action upon it; and it is, I believe, the only salt of magnesia insoluble in acids.

This salt, as well as my process for phosphoric acid, I have minutely described in a paper lately read by me before the Royal Society of Edinburgh, which will be hereafter published. In the mean time, your chemical readers may like to know so simple a means of purifying the acid of bones.

I remain, sir,

Your obedient servant,

WILLIAM GREGORY.

University of Edinburgh,
March 22, 1845.

[REMARKS.—We have great pleasure in inserting Professor Gregory's letter, and if we take the liberty of making any comments we trust he will consider that they are made rather in the spirit of friendly inquiry, than of editorial criticism. It has always appeared to us that there was considerable difficulty in determining the existence of phosphate of magnesia in bone, owing to the presence of phosphoric acid and lime, and the absolute necessity for entirely separating the lime before the existence of magnesia could be satisfactorily determined. The only analyses of human bone with which we are acquainted are those of *Berzelius* and *Thilenius*—that of *Berzelius* is copied by most chemical authorities. Both agree with Dr. Gregory in assigning phosphate of magnesia as a constituent; but *Berzelius* states (vii. 474) that he thinks it probable the magnesia exists in the bone as *carbonate*, and that its separation as phosphate is owing to the analytical method adopted,—the magnesia always precipitating itself with phosphoric acid and ammonia as a double salt, even when there is more lime in the solution than the phosphoric acid can saturate.

Dr. Gregory's plan of detecting magnesia differs, we believe, from any yet suggested. *Berzelius* recommends the entire precipitation of a slightly acid solution of bone (the phosphoric acid) by a solution of acetate of lead. The filtered liquid, deprived of surplus lead by sulphuretted hydrogen and neutralized by ammonia, now allows of the entire separation of lime by oxalate of ammonia, and this liquid, when filtered and evaporated to dryness, leaves, he states, pure magnesia.

The method often pursued by chemists is to dissolve the mixed phosphates of lime and magnesia in a mineral acid; this solution is then nearly neutralized by ammonia, and then precipitated by oxalate of ammonia. The production of oxalate of lime, however, under these circumstances, necessitates the formation of phosphate of ammonia; and the compound phosphate of ammonia and magnesia will therefore be precipitated. This plan has invariably failed to detect magnesia in bone; for in general the filtered liquid only has been examined.

Dr. Gregory recommends sulphuric

CASE OF

POISONING BY PRUSSIC ACID.

COMMUNICATED BY MR. HICKS
AND MR. WATERWORTH.*(For the London Medical Gazette.)*

acid for separating the whole of the lime from magnesia in bone; but, as he used no alcohol, it is a question whether the whole of the lime can be separated by means of this acid. Admitting that sulphate of lime is present in the evaporated bone-liquid, as prepared by our intelligent correspondent, we do not see how the entire absence of lime can be inferred by the liquid remaining clear on the addition of sulphuric acid; since, so far as our observation goes, this acid does not affect a solution of sulphate of lime either by itself or when mixed with phosphoric acid. We would, therefore, beg to inquire, whether the liquid, nearly neutralized by ammonia, does not give a precipitate with oxalate of ammonia indicative of lime; for this test will undoubtedly detect the presence of lime when sulphuric acid entirely fails; as, for example, in common lime-water in a solution of sulphate of lime, or in the bone liquid, as it is commonly prepared for the extraction of phosphorus.

This question does not at all affect the value of Dr. Gregory's ingenious discovery, *i. e.* of procuring the whole of the phosphoric acid in bone, by simply evaporating the liquid at about 600°, and thus procuring a mass which yields soluble phosphoric acid and an "insoluble heavy white powder," for the reduction of which we would suggest to our correspondent the use of the cyanide of potassium in the dry way.

Dr. Gregory's communication will induce us to repeat some experiments on bone, in order to determine whether phosphate of magnesia be really present or not. All that we can say is, that in an experiment conducted, as we thought, with precaution, we could not succeed in finding a trace of magnesia either as phosphate or carbonate. A newly discovered process for rendering phosphoric acid, as it is contained in bone, perfectly volatile at a comparatively low temperature, promises to put it in our power to obtain directly from bone, lime, and, if it exist, magnesia in a caustic state. There will then be no difficulty in determining either the presence or the exact proportion of the alkaline (earthy) bases in bone.—*Ed. Gaz.*]

On Friday, the 21st of March, Mr. Hicks, of High Street, Newington, was sent for in great haste to see a person who was stated to have been suddenly taken seriously ill. On his arrival, he found the patient to be a female about 22 years of age, and of small stature; she was lying on her back perfectly insensible, the teeth clenched, foaming at the mouth, and the face so greatly congested as to be almost purple; the breathing was slow, laborious, and at long intervals, the pulse gone, and the action of the heart but feebly to be felt; the eyelids were partly closed, and the eyes appeared as if pushed forward between them, while the pupils were dilated, and quite insensible to the stimulus of light; the whole body was under such strong spasmodic action, that the head seemed buried between the shoulders, and the arms nearly turned round by the action of the pronators. There was neither emprostotonos nor opisthotonos.

Such were the symptoms as nearly as he can recollect; and from the bloated state of the countenance, together with the foaming state of the mouth, his first impression was that the girl was labouring under some form of epilepsy*; but upon finding the patient pulseless, and the heart scarcely to be felt, he naturally looked for some other cause; when he found, upon inquiry, that the symptoms had come on directly after taking a dose of medicine, which he ascertained by tasting and smelling to contain prussic acid. This led him to the conclusion that the symptoms were produced by an overdose of that medicine; and in conjunction with Mr. Watson, a medical gentleman whom he found at the house upon his arrival, he resorted to the means recommended in such cases—such as cold affusion to the head, applying ammonia to the nostrils, and endeavouring to give brandy and ammonia internally. As, however, the muscles of deglutition were so fully

* No odour of prussic acid was perceived about the mouth, or in the room.

under the influence of the poison, it is doubtful whether more than a small quantity passed into the stomach, notwithstanding every means was used, by irritating the fauces, to stimulate those muscles to action. Their efforts were, however, perfectly useless, as the breathing became gradually slower; and in less than ten minutes after their arrival the patient died,—death appearing to be caused by the perfect inability of the sufferer to inspire, from the muscles of the chest, as of every other part of the body, being under strong tetanic spasms; the natural consequences being extreme congestion of the brain and lungs.

On making inquiries of the father, who was present at the time the medicine was taken, it appears that no sooner was the liquid swallowed, than the girl, who had been previously sitting, started up, throwing her hands over her head, uttering at the same time a loud gasping sound, *but no scream or shriek*; she stood still for a second or two, then running forward about two yards, fell with her head first to the ground; after which she never moved, but continued to make a sort of moaning noise for five minutes. The respiration was accompanied by a sound very much resembling that observed in laryngismus stridulus. The ribs appeared to become fixed by a sudden tetanic spasm of the muscles. The time which elapsed between the taking of the liquid and death was *twenty minutes*. The deceased died ten minutes after the arrival of Mr. Hicks.

Post-mortem appearances.—At *ninety* hours after death (or nearly four days), the body was examined, when the following were the appearances presented. Externally there was great lividity, the teeth firmly clenched, and there was foam about the mouth.

Head.—The dura mater and sinuses were much congested, and the whole substance of the brain was dotted with blood, which was fluid, and exceedingly black. Ventricles empty; no odour of prussic acid in this cavity.

Thorax.—The lungs were much congested, otherwise healthy; heart small, and of feeble power; the right ventricle slightly dilated, but the valves healthy; the whole organ was filled with blood, which was perfectly fluid, and of a very dark colour. The odour of prussic

acid on opening this cavity was very evident, not so much from the smell as from the sense of constriction produced in the fauces.

Abdomen.—The stomach contained about two ounces of undigested food, smelling strongly of prussic acid, the organ itself appearing healthy, with the exception of a small patch near the cardiac orifice, which was red and vascular. This, Mr. Hicks, however, is inclined to think was not the effect of the poison, but that it had existed for some time, as it was for some form of dyspepsia that the patient was taking medicine.

The liver was healthy, as well as all the organs in the abdomen; there was no tinge of blue about the gall-bladder, or in its contents.

The contents of the stomach being taken to Dr. Letheby, of the London Hospital, were submitted to examination, in the first place, by putting them into a retort and distilling by means of a water-bath, by which process two drachms of fluid passed over, smelling of prussic acid, a portion of which being tested by the iron test gave evidence of the poison by the formation of Prussian blue, and afterwards, by testing with the nitrate of silver, a white precipitate was produced, insoluble in cold, but soluble in boiling nitric acid; and on heating the cyanide of silver in a small reduction-tube, cyanogen was evolved, which burnt with a purple flame; these tests satisfactorily proved the presence of prussic acid.

The next point to be considered was the determination of the quantity of prussic acid taken by the deceased. From information supplied by Mr. Hicks, it appears that one half of the mixture, which was intended for a lotion, yielded on distillation and the precipitation of the distilled liquid by nitrate of silver, nine grains of cyanide of silver. In the whole mixture, therefore, amounting to four ounces, there would be a quantity of prussic acid equivalent to eighteen grains of the cyanide of silver. This would amount according to the usual calculation to three grains and six-tenths of anhydrous prussic acid. The deceased had swallowed by mistake one-fourth part of this lotion: she had, therefore, taken *nine-tenths of a grain* of anhydrous prussic acid. Taking Scheele's

acid at five per cent., this would be equivalent to eighteen grains, or rather less than twenty drops of Scheele*: and, on comparing it with the Pharmacopœial acid, at two per cent. this quantity of anhydrous acid would be equivalent to forty-five grains, or forty-nine drops.

REMARKS.—This is probably the most interesting case of poisoning by prussic acid which has been yet recorded. The history is in every respect complete: the poison was accidentally swallowed in the presence of a person, who was able to observe and give a good account of the symptoms to Mr. Hicks. This gentleman arrived ten minutes before the death of the deceased, and noticed for himself some of the most striking symptoms;—a complete inspection of the body was made,—the post-mortem appearances were accurately noted, and lastly, the exact quantity of poison swallowed by the deceased, was most satisfactorily determined by a chemical examination of the lotion.

In respect to the symptoms, it would appear, from the father's statement, that he first heard a gasping noise, but there was no shriek or scream. This case, then, appears to put an end to the theory that poisoning by prussic acid is always accompanied by a "death-scream" or "shriek,"—a subject of discussion at the trials of Belamy and Tawell*. There was the slow laborious breathing at long intervals, foaming at the mouth, protrusion of the eyes, dilated pupils, pulselessness, and insensibility. Mr. Hicks states that there was no stertor; that during the convulsive fits the head and neck seemed to be spasmodically drawn down into the chest. The convulsions do not appear to have been so great as to affect the trunk. Emprosthotonos and opisthotonos were absent; a fact which may account for the want of

evidence of a distorted or convulsed state of the body, with disturbance of the clothes, in persons who have been found dead in bed, and who had taken prussic acid. The most remarkable part of the case is, that the girl obviously retained volition and the power of locomotion for a short time after swallowing the dose. She was able from a sitting posture to assume the erect attitude, throw her arms above her head, and then run a short distance before she fell. When seen by Mr. Hicks she was perfectly insensible, and unconscious of everything that was passing around her. She made the same moaning noise before death, that was observed in the case of Sarah Hart.

The most striking of the post-mortem appearances were,—the fluidity* and dark colour of the blood. It does not appear that the blood had any odour of prussic acid, although this odour, or rather a *sensation* which some experience in smelling the acid instead of odour, *i. e.* "*constriction of the fauces*," was perceived by some of those present on opening the cavities of the thorax and abdomen. The contents of the stomach smelt strongly of prussic acid, *i. e.* gave a constricting sensation in the fauces, and this was observed *ninety hours* after death. In a case examined by Mr. E. Crisp, of Walworth, where it is probable a considerably larger dose of the poison was swallowed, there was no odour of prussic acid in any part of the body, although the examination was made seventy hours after death†. Facts of this description show that the detection of an odour is a very uncertain attendant on poisoning by prussic acid. The term "*odour*" appears, indeed, to be improper, when applied to a sensation experienced in the throat; many can detect no odour at all in prussic acid, although they have an undefinable sensation of its presence. One point is quite certain, that those who look for an odour of bitter almonds in these cases will commonly be deceived, and pronounce the poison to be absent. It is very easy for a person who has tried some experiments on the subject to distinguish the smell of prussic acid from that of bitter almonds; but it is a

* Two drachms of what was said to be Scheele's acid were put into the bottle, but the analysis proved that the acid must have been under the strength of Scheele.

† Another case of poisoning by prussic acid, without any "shriek or scream," was reported in the MEDICAL GAZETTE of last week. See page 859. Mr. Hicks took especial care to ask the father as to the kind of noise made by the patient on taking the poison, and from the description he gave, it does not warrant the assumption that any peculiar shriek is made in death from prussic acid. It was a mere gasping for breath. See also a third case, Edinburgh Medical and Surgical Journal, Vol. 48, p. 44.

* In Dr. Meyer's experiments on animals, the blood was found coagulated. Schmidt's Jahrbücher, 1844.

† Lancet, Sept. 14, 1844.

question whether many do not actually seek for the smell of the latter, as evidence of the presence of the poison.

It is not a little singular that in this case, the odour of prussic acid was more distinctly recognised in the thorax than in any other cavity! Some who were present perceived it more strongly in the chest than in the abdomen, even after the stomach itself had been laid open.

The only other appearances remarked, were congestion of the lungs and brain. The heart was filled with blood; the aorta empty. There was no blue tint in the contents of the gall-bladder; the kidneys had a pinkish colour, and were much congested.

The most important fact which this case discloses remains to be mentioned; it settles beyond all dispute that the *life of a healthy adult may be destroyed by a dose of anhydrous acid equal to nine-tenths of a grain*. Dr. Geoghegan* has described a case in which a gentleman narrowly escaped with his life after having swallowed a quantity of the acid equivalent to *thirty-six* drops of the London Pharmacopœial acid. In Mr. Hicks's case a quantity equivalent to *forty-nine* drops of the same acid was taken, and the person died in twenty minutes. In a case reported by Dr. Banks, a female recovered after taking thirty drops of an acid, the strength of which is not stated!† It is, however, quite possible that a person might die from a smaller dose than that taken by the deceased in this instance, because circumstances may cause the effects of the same dose to vary in its operation on different persons. Another point worthy of remark is, that the quantity which certainly killed this woman was actually less than that which was found to be present in the stomach of the woman Hart: and yet it was absurdly attempted, in the defence of Tawell, to show that there was not enough of the poison found to destroy life! We have, then, in cases of Dr. Geoghegan, and Mr. Hicks, the clearest proof—1, that a person has recovered from a quantity equivalent to thirty-six drops of P. L. acid (fourteen of Scheele); and 2d, that a person has died from forty-nine drops of the P. L. acid (twenty drops of Scheele‡). It appears to be impos-

sible to have the fatal dose of a poison fixed with greater precision*.

* All English medical jurists have hitherto laid it down that *three-quarters* of a grain of anhydrous prussic acid might be regarded as a fatal dose. When we consider the alarming symptoms produced by *two-thirds* of a grain in Dr. Geoghegan's case (the patient having had a most narrow escape of his life), and that death has here been caused by *nine-tenths* of a grain, it will show that the opinion thus expressed by Christison and others, is perfectly borne out by facts. It has been objected that the dose given in the cases upon which this opinion was based (*i. e.* the cases of the seven Parisian epileptics), had been misstated by all English writers, and it does appear that an error has crept into every English work on toxicology, in relation to the dose which proved fatal in these instances. The error, however, is but little more than the *third* of a grain, as the following calculation will show:—

Each patient took a dose of sirop hydrocyanique du Codex, containing ten per cent of medicinal prussic acid. According to Orfila, the quantity of medicinal acid in each dose was twenty grains (French), or 16·94 grains English (Ann. d'Hyg. 1829, 507). In another report Orfila states that each patient took of medicinal acid one gramme fifteen centigrammes, or 17·75 grains English (Toxicologie, ii. 285). It will be observed that here is a difference of 0·81 grain of medicinal acid in the dose taken. Gay-Lussac, Magendie, Barruel, and Orfila, were employed by government to determine the strength of the sirop hydrocyanique du Codex; and that this was the same as that prescribed for the patients appears evident from the identity in the specific gravity and proportion of acid present (Ann. d'Hygiène, 1829, pp. 495–504). They found, by careful experiment, that ten grains (French), or 7·7 grains English, of the acid used in the syrup, gave, with nitrate of silver, 15 centigrammes, or 2·31 grains, of washed and dried cyanide of silver. Thus, then, 100 grains of the medicinal acid, used in the syrup, would yield 30 grains of cyanide of silver, and this would indicate a strength of *six* per cent. of anhydrous prussic acid. Admitting Orfila to be correct in stating that each patient took in the dose of syrup 17·75 grains (English), of medicinal acid, this would be equivalent to 1·06 grains of anhydrous prussic acid,—a dose only a little greater than that taken in Mr. Hicks's case.

It has been stated that each patient took 24 grains of anhydrous acid,—Devergie says 5·64 grains (French) = 4 grains English of concentrated acid: but not to mention the proof to the contrary in the above calculation, the symptoms and duration of these cases much more clearly resemble the effects of a dose of about a grain of anhydrous prussic acid, than those of a dose of two or four grains; and the mistake in the quantity has arisen probably from a calculation of what the strength of the acid *ought* to have been, rather than what it was found to be. Two grains and a quarter of anhydrous acid are equal to about 50 grains of Scheele, and 120 grains of the P. L. acid. Some of the epileptic patients survived three-quarters of an hour; but had the dose been so large as above supposed, it is highly probable that they would have died in a much shorter period of time. This result shows that we have in Mr. Hicks's case the smallest dose of prussic acid which has yet destroyed life: but this does not at all affect the opinion that three-quarters of a grain of anhydrous acid might act as a fatal dose,—an opinion to which we believe all toxicologists would assent.

‡ It is here assumed that Scheele's acid contains 5 per cent. of anhydrous acid, but it is seldom found so strong as this.

ANALYSES AND NOTICES OF BOOKS.

“L'auteur se tue à allonger ce que le lecteur se tue à abrégé.”—D'ALEMBERT.

The Diagnosis, Prevention, and Treatment, of Diseases of the Heart, and of Aneurism. With Observations on Rheumatism. By J. J. FURNIVALL, M.D. London, 1845. 8vo. pp. 216.

THERE are several difficult and obscure subjects in pathology upon which it appears to be almost impossible to write either too much or too often; providing always that the authors are neither quacks nor tyros, but men of experience and research, whose efforts are continually bent to the honest purpose of removing the doubts which beset the subjects of their inquiries. Among the chief of these topics are phthisis, malignant disease, and cardiac affections.

The greater part of the work before us appears to be made up of such observations of other writers as the author considers to have stood the test of his own experience: it would be difficult to point out more than one or two doctrines in the book which have altogether originated with himself, and yet, after carefully noting his views, especially those on the general pathology of the diseases, and the principles of their treatment, it appears to us that very few writers have appreciated so justly as he has done the real characters and tendencies of cardiac affections, and the rational plan upon which they should be treated. We allow this freely, with regard to his general doctrines, although we shall have to differ entirely from him in several of the details.

The work is divided into ten chapters; the principal of which treat of pericarditis, endocarditis, hypertrophy, dilatation, diseases of the valves, observations on the treatment of aneurism, palpitation, and functional disorders, and observations on rheumatism and on the prevention of heart disease. Under these heads are included the diagnosis, prognosis, and treatment of each class of disease. It is fairly stated, in the preface, that “the diagnosis is a practical digest and compilation from the latest authors who have written on the subject.” This plan certainly has its advantages; but it appears to us that, in more than one instance, a too close adherence to the somewhat un-

proved opinions of others has taken from his remarks that practical character which is always so discernible in a work of actual observation. We shall now proceed to make extracts from those parts of the work which appear to contain the most prominent and useful of the author's opinions. The following remarks occur in the “General Observations on Diagnosis.”

“It would be well could we always and with certainty distinguish between functional disorder, and organic disease of the heart; but this is not always to be done. This circumstance will, at times, prove a comfort to both practitioner and patient; as it should prevent the former from either giving or entertaining too gloomy an opinion while he awaits the results of treatment, and the latter can entertain more hope of recovery than if his medical adviser could decide that there is organic and incurable disease. We shall be aided in this diagnosis by observing whether the symptoms have arisen suddenly or come on gradually; whether they are intermittent or constantly present. Wherefore we should at the very outset inquire whether the dyspnoea (usually the first symptom) is a constant attendant upon every exertion of muscular power.” p. 13. In another place it is observed, “Functional palpitation occurs only occasionally; it is not excited, but often relieved by corporeal exercise; and this is a very distinguishing mark, for organic palpitation is both excited and augmented by exertion, even very slight exertion; it may come on, while quiet though wakeful, in the night; it is accompanied by nervous symptoms; during the intervals the pulse and action of the heart are natural; and this is another distinguishing mark.” p. 189.

The following observation is familiar to most practical auscultators, but is of great value. “Let not the student be discouraged if he shall on some days distinctly hear certain sounds which on other days are obscure, or not to be heard at all; for, as I have already said, the sounds will vary from the effects of treatment, and other causes. Treatment will often exert a marked influence over the sounds, so as to cause a new comer, examining for the first time, to suspect or even to deny their existence altogether, past or present.” p. 15. In discussing the pro-

bable causes of the greater frequency of the occurrence of the disease in the left cavities of the heart than in the right, Dr. F. argues that as the "fully elaborated arterial blood is the natural stimulus to the heart's action," this blood, "highly elaborated, and rich as it is in stimulant material, may be rendered by disease more stimulating to the parietes of the cavities and canals through which it circulates, than the venous would be to the right ventricle." p. 17. It would require further chemical data than we at present possess to establish the correctness of this theory. It is not easy to perceive why, even under a diseased condition of the fluids, the more elaborated arterial blood should have a greater irritating influence on the tissues which it permeates than the venous fluid has, which comes to the heart loaded with many impurities. We have always attributed the greater tendency to disease of the left cavities, in some measure, to the comparatively unyielding nature of their structures, the closeness of the valves, and the great and almost rigid power of the ventricle, all of which circumstances must have an influence in rendering the parts more liable to mechanical injury, upon occasions of obstruction and over-excitement. In nine-tenths of the cases of mechanical lesion of the heart, the mischief is found to have occurred on the left side: the right cavities are more accustomed to obstructions, are more pliable and elastic, and therefore do not so readily suffer from over-distension. It may be, too, that the cavities on this side of the heart are naturally more adapted to the reception of irritating fluids than those on the left: as, in health, the former receive the highly carbonized fluid from the veins, and the latter are accustomed to transmit only a perfectly depurated stream, so, in disease, a strongly azotized or otherwise morbid fluid may be conveyed with impunity by the right cavities, while it produces the most irritating effects upon the left. All are aware that pungent substances, which can be borne without injury on the mucous membrane of the lip, produce the most violent inflammation if applied to the conjunctiva of the eye; and yet it would be difficult to assign for this any other reason than that of necessity. One of the most prominent of the author's opinions is the depen-

dence of rheumatism, and the consequent pericardial and endocardial affections, upon the existence of a morbid state of the blood itself. In its general bearings this view is, we believe, shared with him by many pathologists of the present day. Dr. Furnivall rests his theory upon the following grounds. "An excess of fibrine has been detected in the blood of rheumatic persons; which excess must render it highly and morbidly stimulant. Probably there is also some other arrangement of its primary components, which, in the present state of our knowledge, may be best described by saying that it is relieved by an elimination of acid through the secretions, and best obviated in treatment by the use of alkalis. Possibly lithic acid may exist in excess in the form of lithate of soda." He adds, that Dr. Schönlein holds this opinion also. The chapter on pericarditis contains much that is deserving of attention. The following view is, we believe, rather opposed to the opinion generally entertained: "Pericarditis seldom precedes endocarditis, for the signs of the latter are generally first to be met with." p. 34.

An observation on the diagnosis of adherent pericardium, by an experienced auscultator, is here introduced. It first appeared in this journal, but is worth re quoting. Mr. Aspland says, "In a healthy individual sitting erect the apex of the heart strikes at two inches below the left nipple, and one inch nearer the sternum. If lying on the left side it strikes in a line vertical with the nipple; if lying on the right, it strikes in a line with the edge of the sternum. In adherent pericardium this mobility is lost. The apex of the heart does not change its place of beating by any change in the patient's position." Dr. F. has never failed to remark labouring action of the heart in pericardial adhesion. The opinion of M. Forget, that occasionally "scarcely any appreciable embarrassment is caused thereby to the movements of the heart," will also find its advocates: it is true that adhesion seldom fails to be attended eventually with fatal disorder of the cardiac functions, but many instances occur in which, while the organ remains free from hypertrophy, its valves being healthy, there is certainly no observable disordered action. The author

considers that a different plan of treatment is required in uncomplicated cases of pericarditis from that which is proper in acute pericardial inflammation. In the former this must be as vigorous as the strength of the patient will allow. "Bold venesections on the first day, then cupping and leeching as freely as possible; this is, supposing there is no endocarditis." p. 45. In the latter disease, he says, "the treatment usually recommended is that of pericarditis; and if by that be meant pericarditis complicated with endocarditis our practice will be correct, and in the great majority of cases such a complication will occur; but the treatment of uncombined pericarditis differs from that suitable to endocarditis, as it will admit of more energetic treatment than will endocarditis. In the latter syncope might be fatal, and we therefore must use the lancet very carefully; while in pericarditis we may bleed with much boldness. Agam, nausea unto faintness will prove beneficial in the latter; but in the former, where the fibrine renders the current of blood through the heart very sluggish, faintness from languor may favour depositions of fibrinous concretions." p. 62. In this latter disease, therefore, we are recommended to employ "one or two bloodlettings, avoiding the slightest approach to syncope; then local detractions of blood will be preferable, and cupping and leeches might be prescribed, according as circumstances seem to require." The remainder of the treatment will consist principally in the use of mercury carried only to the extent of producing tenderness of the gums, and alkalis, which the author regards "as almost specifics in this disease, as they seem to reduce the abnormal thickness of the blood very speedily and very effectually." p. 64-5. The distinctions which Dr. Furnivall here lays down may perhaps be followed out, and with advantage, by experienced physicians, but we doubt whether they have not a tendency to perplex many of the class of men to whom this work is more especially addressed—students and junior practitioners. It is represented that there are here two diseases—pericarditis and endocarditis, which require to be very differently treated:—we are also told, and few are unaware of the fact, that these diseases frequently coexist, and

that the diagnostic distinctions between them are not always very clearly defined; for although Dr. Furnivall lays it down as a rule that the existence of a bellows-murmur in cases of pericarditis may be taken as an assurance that endocarditis is also present, (p. 35), we have seen more than one experienced auscultator at fault in deciding whether a sound of this kind arose from the interior or exterior of the heart; and, we submit, it would be difficult to disprove the fact that the most frequent sign of mere pericardial inflammation is a murmur of this character. Indeed, in the very next page (p. 36) Dr. F. himself, in describing the characteristics of pericardial bruits, says, "The character of the sound varies; it may resemble the rumpling of silk or parchment, the creaking of new leather, the sound of a rasp, or it may be merely a bellows murmur." Under these circumstances we do not perceive that Dr. Furnivall makes out very clearly the distinctive marks by which it can be perceived that one or other class of treatment should be adopted. For our own part we have always been opposed to the use of extensive depletory measures in severe cases of rheumatic pericardial and endocardial inflammation. In the lighter cases of the former disease, that is to say, where the patients are young, stout, and vigorous, active antiphlogistic means are often successful; but, where the pericarditis occurs in a patient who is at all debilitated, free general bloodletting appears to us to be a most dangerous measure, and we have certainly seen the symptoms of pericarditis become aggravated after depletion in weakly patients, so rapidly, and to so formidable a degree, as to render it evident that the treatment had aggravated the disease and placed life in imminent jeopardy. It is probable that, in most cases of pericarditis, there also exists more or less of pericardial complication, but the cases where the symptoms of inflammation of the lining of the heart become very evident are generally those in which the patients have been previously unhealthy; and here the inflammatory symptoms, assuming a low type, altogether contraindicate the French system of treating endocarditis by extensive bleedings. We should be glad, did our space admit, to quote from the author's views on the treatment of hypertrophy, which

are very just: we can only give the following isolated passages. "Our indications of treatment are two-fold—one, to reduce the irritability and abnormally great action of the muscular fibre itself; the other, to diminish the quantity of fluid in the ventricle until there is as little fluid remaining in it as may consist with a due performance of its vital functions." "A reduction of the mass of circulating fluid is important; for as the quantity lessens so will the ventricular parietes adapt themselves to their contents." "One great point (in the treatment) is abstaining from much drink, and as dry a diet must be followed as the patient can bear." p. 75-7. The author's views are principally extensions of the opinions of Hope and subsequent writers, but they are well given, and appear to be delivered by one who has tested them by his own experience, and proved their value. We would apply the same encomium to his principles of treating dilatation, (p. 102.)

We are happy to find that Dr. Furnivall agrees with those who are generally opposed to the internal administration of digitalis in organic diseases of the heart, which he does, not only on account of the aggravation of symptoms which this drug is liable to produce, but from the fact of its favouring the tendency to further distension and dilatation of the cavities of a diseased heart. He objects to it, also, because it is apt to produce nausea and gastric irritation, and with this gastric irritation he has found that it ceases to lower the pulse—it raises it—neither will it then act as a diuretic. The author observes, in another place, "Its influence is to enfeeble the action of the heart, and retard the circulation of the blood; consequently, it will promote the stagnation of the blood, the very thing it is our object in this disease to avoid" (he is here speaking of endocarditis, but the same remark applies equally to all other diseases of the heart): "it has been banished by all good practitioners from all diseases of the heart attended with debility of the organ." p. 64. He has, however, used digitalis endermically, with advantage (applying the powder to an abraded surface on the chest), in paroxysmal attacks of palpitation and dyspnoea attendant upon organic disease.

The only form of heart disease in

which he would give this medicine internally is that of hypertrophy of the right ventricle in complication with narrowing of the mitral orifice. Upon this point we shall presently offer one or two dissentient remarks. A good deal of interesting matter is contained in the chapter on "Diseases of the Valves," but we doubt if this portion of the work has received so much care from the author as its importance required. It is evident that neither Dr. F., nor many of our English auscultators, will be willing to admit, with Professor Forget, that in organic disease, "whether it be the aortic or mitral valve that is affected, it is never easy to say." We think that many would be found to differ from Dr. Furnivall in the opinion stated at p. 132, that in great contraction of the aortic valves the pulse is generally "intermittent and irregular." In the following page it is stated, that "obstructive disease is accompanied by a hard, jarring pulse." No allusion is made to the peculiar musical, whistling, or cooing sound which is so characteristic an attendant upon the diastolic movements in cases of regurgitant disease accompanied with retroversion of the aortic valves.

The remarks upon the treatment of dilatation accompanying disease of the valves are worthy of careful perusal; we must, however, venture to differ from the author in his opinion, expressed at p. 147, that an entirely opposite plan of treatment should be adopted in cases of obstruction of the mitral valve to that which is indicated in aortic valve disease. He appears to have arrived at this conclusion from adopting the now generally discarded opinion of M. Bricheteau, that, in the former case, the forcible action of the hypertrophic right ventricle is the cause of the pulmonary hæmorrhages and obstructions which are such frequent and dangerous attendants upon mitral narrowing; and that it is therefore requisite to reduce the muscular and propulsive power of the right ventricle. In this disease alone, then, he recommends the use of digitalis, combined with tonics, and says that here detractions of blood, and the use of hydragogue purgatives, as elaterium, may also be employed, p. 149. In speaking of these cases, he remarks: "Digitalis is peculiarly serviceable,

for it protects the lungs from the too powerful action of the right ventricle, it lessens dyspnoea, it prevents hæmoptysis, and allows the left ventricle to be less overpowered by the onward pressing current." p. 171. Now, we believe that, in cases of simple mitral obstruction, the left ventricle is never embarrassed with too great a pressure of blood, until a very late period of the disease, when venous obstruction begins to produce delay in the systemic arteries; but, on the contrary, this cavity is not unfrequently found small and contracted, evidently from the scantiness of the current which it has had to transmit. In narrowing of the mitral orifice the right ventricle is placed nearly in the same pathological condition as the left ventricle is when its outlet becomes contracted; and the ultimate consequences are, upon the whole, nearly the same in both instances—that is to say, the obstruction, in either case, produces engorgement of the ventricle behind it: the delay to the transmission of blood, thus occasioned, is for a time partially compensated by hypertrophy and increased propulsive power in the muscular walls of that cavity; but, from the first onset of the disease, permanent dilatation of the ventricle gradually advances in each instance; and whenever this arrives at the point of counterbalancing the increased power which hypertrophy has given to the muscle, the ventricle becomes incapable of contracting, and death results. Now, we are aware that dilatation does not make such rapid progress in the right ventricle, under the circumstances mentioned, as it does in the left, when that cavity is similarly embarrassed owing to the interposition of the pulmonary vessels of the left auricle; it is also to be admitted that while there is more hypertrophy than dilatation, and the heart still acts vigorously, digitalis, and other depressing agents, do not usually produce any very apparent serious results; and when this medicine acts as a diuretic, a quantity of fluid is thus removed from the system, and the symptoms are, for a time, relieved. But it is also certain that the ultimate tendency of mitral disease is to weaken and incapacitate the right ventricle, and that the hypertrophy of this cavity is a provision of nature by which alone it is enabled to carry on the circulation. Is it, then, here a judicious

course to make use of a remedy with regard to the effects of which we shall again quote the author's own words: "its influence is to enfeeble the action of the heart, and retard the circulation of the blood"? We have long thought that in all organic diseases of the heart the use of digitalis should be discontinued on principle, as it always tends, more or less, to produce that weakened condition of the organ which, in the ordinary course of the disease, ultimately proves fatal, and as the temporary benefit which ensues from its diuretic effect might always be produced with more safety by remedies which do not in any way depress the action of the heart. In a practical and elementary work, professing to embrace the whole treatment of cardiac disorders, we are surprised to see but very slight allusion made to the influence of pulmonary affections in aggravating the symptoms of valvular and other organic diseases, and that very little stress is laid upon the necessity of watching, with the utmost solicitude, the condition of the pulmonary functions in these states. Very few patients, comparatively, die from the ultimate effect of cardiac obstruction—complete inability of the heart to contract; by far the greater number perish from the superaddition of bronchitis, or some other inflammatory condition of the lungs. Very slight cardiac lesions will determine a fatal result in cases of pulmonary disease; while, on the other hand, it is often surprising for how many years persons affected with almost extreme valvular disease continue to enjoy tolerable health when the lungs remain in a healthy condition. It is very observable that in mild winters comparatively few cases of heart-disease present themselves to our notice; while, at the commencement of a severe season, patients thus affected begin to crowd the wards of our large hospitals, like withered leaves which the first sharp gusts of winter have driven from their branches.

Although we differ from Dr. Furnivall in certain of his conclusions, we do not hesitate to say that his work contains much that is valuable. Most persons will admit that the faculty which enables an author to appreciate and extend the useful suggestions of others is scarcely less meritorious than that which leads to the observation of

novel facts. We have little doubt that had the author observed the caution of retaining his manuscript a few months longer, further consideration would have led to the correction of the occasional inconsistencies which detract from, but do not destroy, the value of the work. We recommend its perusal, and repeat, that, upon the whole, the author will be found to have displayed in it a just appreciation of the pathology and general treatment of cardiac diseases.

MEDICAL GAZETTE.

Artis Medicæ tueri; potestas modo veniendi in
publicum sit, dicendi periculum non recuso.”

CICERO.

REGISTRATION AS IT WILL AFFECT FUTURE PRACTITIONERS.

IN our last number we discussed the various questions which have arisen respecting the registration of medical men now legally engaged in practice. We propose on the present occasion to say a few words respecting the registration of future practitioners. So far as concerns both classes, we must regard this registration as compulsory; for whatever may be the professional qualifications of a man who omits to have his name inserted on the register, he will no longer be regarded in law as a member of the medical profession; and he will be deprived of all the legal rights (few as they are) which the bill secures to registered practitioners. It is important that this should be well understood; for something has been said about the registration being “optional,” or only “inferentially compulsory,” &c. It was even at one time proposed, and we do not know that the scheme is yet entirely abandoned, that an attempt should be made to defeat the whole measure by a general refusal to register. An Act of Parliament, however, when once passed, cannot

be thus set at defiance, and the unregistered would be taught, when too late, that by taking such a course they had acted most unwisely. The penalty would be a recommencement of their studies, followed probably by a more severe examination than that which they had already undergone.

The clause which affects the registration of future practitioners is the 13th. It runs as follows:—

“And be it enacted, That a Register shall be kept and published from time to time, under the direction of the said Council, of all persons who shall have been examined, and shall have received, and shall exhibit before the said Council, Letters Testimonial as hereinafter mentioned of their qualification to practise as a Physician, or as a Surgeon, or as a Licentiate in Medicine and Surgery; for which registry the Council shall be entitled to have from the person requiring to be registered a fee of *Five Pounds* in the case of a Physician or Surgeon, and the fee of *Two Pounds* in the case of a Licentiate, which fees shall be applied toward defraying the expenses of this Act; and every person whose name shall be so registered, who shall be desirous that his name shall be continued in the published Register, shall in the month of *January* in every year send to the said Council his name and place of abode, with the date of his Testimonials, and the Council shall verify the returns so made to them by comparison with the Register kept by them, and shall forthwith, without any further fee, cause the names of all persons duly registered and so returned to them to be published in alphabetical order in their several classes, with their several places of abode, and dates of their Testimonials.”

There can be no doubt about the meaning of this clause. The registration fee is here five pounds for physicians and surgeons, and two pounds for licentiates. For our parts we do not see why this fee should not have been higher for the *future*, and lower for the *present* race of practitioners. The present holders of two diplomas, hav-

ing already paid a high sum for their qualifications to practise, should have been allowed to register at a mere nominal fee, especially as, under the bill, they are to be placed on the same footing as those who will hold only one. The regulation of fees for future diplomas, being placed in the hands of the Council of Health, might have been made proportionally lower.

Under this clause, it will be observed—there must be an *annual* registration in the month of January, or an individual will forfeit his rights as a registered practitioner. This annual registration will entail no additional expense, but the practitioner must take care that through his own neglect, his name is not struck off the register. This regulation applies both to present and future practitioners, although it occurs only in the clause referring to the registration of the latter. What is required of a practitioner, in order that he should thus retain his legal rights, is so fully explained in the clause itself, which we have here reprinted, as to render any further comment from us unnecessary.

Our readers must, we fear, be already wearied of the subject of the various grades of practitioners proposed to be created under the new Bill, comprising the "Licentiate," or general practitioner of *twenty-one*,—the "Surgeon" of *twenty-five*,—and the "Physician" of *twenty-six*. In order to meet the difficulty urged respecting the age fixed for the "physician," the framers of the bill have added an intermediate class, "inceptors in the Faculty of Medicine," at the age of *twenty-two*. In fact these are merely "Licentiates" under another name, with one year added to the age. The distinction between this class and that of the licentiates, except in name, is not very apparent, and the necessity for its creation is questionable.

It has been already explained that a

double registration is not allowed under the new bill. Thus, with respect to future practitioners, if the licentiate become a surgeon or physician, he will not be permitted to have his name on the list in a double capacity. He must make his election,—a rule not carrying with it the injustice which exists in this respect with regard to present practitioners.

Under the 20th clause of the bill, every registered "Licentiate in medicine and surgery" becomes *ipso facto* a member or licentiate of the Royal College of Surgeons, in that part of the United Kingdom in which he shall have received his letters testimonial,—so that the future "licentiates in medicine and surgery" will have the same *status* as the present members of the College, who have been excluded from the fellowship, except that they cannot register themselves as surgeons. There is no part of the bill, however, as we shall presently see, which prevents them from assuming that title.

The new measure, we are glad to perceive, creates a power of granting medical degrees by special license without examination. The restrictions on the granting of medical degrees will be found in the 22d clause, and it is here expressly provided that the Council of Health may allow such degrees to be granted by special license. We have long thought that, under proper regulations, there should be a power in the Universities to grant honorary degrees. Let us take the case of a licentiate or a surgeon who may have passed twenty or thirty years in the successful practice of his profession. He might wish in the decline of life to enjoy the title of M.D.; but so long as a fresh course of study and another examination are rendered compulsory, it may be utterly impossible for him to obtain it. The time for re-studying his profession to encounter an examination, must

be considered as long since passed, in the case of one who has gone through a successful practice, and acquired a good professional reputation. What more than this could reasonably be demanded as a qualification, of a man who wished to have the degree conferred upon him? Some might consider it an empty title, but the public would not the less regard it, when thus bestowed, as a mark of honour and respect. Again, the examiners appointed by the Colleges may be actually the professional juniors of the old licentiate, and may not be so well known either to the public or profession. It could not be expected that, for the sake of a degree, the possession of which he might reasonably desire and justly merit, any one would submit to an examination under these circumstances. There are, we believe, many in the profession, some engaged in practice, and others who have devoted themselves to the scientific cultivation of medicine, who would gladly avail themselves of this privilege; and, by giving this power to a University, only under the special license of the Council of Health, it does not seem probable that it can ever be abused.

The question has been asked—whether a person registered under one denomination, will expose himself to any penal consequences by assuming another name or title than that under which he is actually registered? For instance, can a licentiate be punished for falsely pretending to be, or taking the name of, physician or surgeon? Judging from the words of the 35th clause, it would appear that a false pretence of this kind, is only a misdemeanor or offence in an *unregistered* person:—

“And be it enacted, that every unregistered person who shall wilfully and falsely pretend to be, or take or use the name or title of, physician, doctor, bachelor, or inceptor in the faculty of medicine, or surgeon or licentiate in medicine and surgery, or apothecary, or any name, title, or addi-

tion implying that he is registered under this Act, or recognised by law as a medical or surgical practitioner, shall be deemed guilty of a misdemeanor, in England and Ireland, and in Scotland of a crime and offence, and being convicted thereof, shall be punished by fine or imprisonment, or both, as the court before which he shall be convicted shall award.”

We do not think, however, from what we know of the profession, that the false pretence is likely to be so limited; although, if care be taken in the examination of licentiates, the assumption of another title by a *registered* person can hardly be attended with any detriment to the public.

With regard to any medical title assumed by other persons *not registered*, it will be seen that the words of the clause strictly limit the offence to the assumption “of any name, title, or addition,” implying that he is registered under this Act, or recognised by law as a medical or surgical practitioner.” The restriction thus put upon the false pretence appears absolutely to neutralize it. A man may assume numerous titles implying that he is a *practitioner in medicine and surgery*, and these titles may have the same effect with the public as those enumerated in the clause, but it may be very questionable whether they will be considered to imply “that he is registered under the Act;” and without this, there is no legal offence.

QUARANTINE LAWS.

It appears that the governments of France and England are about making considerable improvements in the mode of carrying out the laws of quarantine. The Austrian medical officers appointed by that government, have not yet made any report of the efficiency of the present system of quarantine in preventing the importation of plague. All are agreed that some mitigation in these laws is not only necessary to commerce,

but actually called for by the altered views on the subject of contagion now entertained by the medical profession.

ROYAL COLLEGE OF SURGEONS.

THE NATIONAL ASSOCIATION OF GENERAL PRACTITIONERS IN MEDICINE, SURGERY, AND MIDWIFERY.

To the President, Vice-Presidents, and Council of the Royal College of Surgeons of England.

GENTLEMEN,—We are requested by the Committee of the National Association to forward you a copy of the following resolution, unanimously passed, at a very numerous meeting of general practitioners, held at the Hanover Square Rooms, on Friday last, the 14th inst. :—

“Resolved, That the National Association records its solemn protest against the proceedings of the Council of the College of Surgeons, in obtaining, and in subsequently carrying out, the recent charter, whereby a few gentlemen have been arbitrarily elevated over the heads of others previously their equals in professional rank—senior to many of them as members of the college, and not inferior to most of them in scientific and practical knowledge.”

And, in compliance with a suggestion offered by the Right Hon. Sir Jas. Graham to a deputation of the National Association on the 14th of February, to request the favour of an early answer to the following inquiries :—

1. Is the Council of the College prepared to reconsider their charter, and to place those members who were in practice before it was granted, on a level with the fellows ?

2. Is the Council of the College disposed to admit to its board a fair representation of the members of the College in general practice ?

3. Would the Council of the College be willing to co-operate with the National Association in the formation of a Court of Examiners in medicine, surgery, and midwifery ?

And as a further duty has now devolved upon the committee, by a resolution of the general meeting “to use every practicable means to obtain a charter of incorporation for the general practitioners,” they are desirous to ascertain how far, and in what manner, the Council of the College of Surgeons may be disposed to assist the National Association in the attainment of its object.

Should the Council be pleased to entertain these propositions, the Committee will be happy to appoint a deputation of its mem-

bers for the purpose of an early conference, on a subject so important to the best interests of the profession and the public.

We have the honour to remain, gentlemen,

Your most obedient servants,

JAMES BIRD,

HENRY ANCELL,

Hon. Secs. *pro tem.*

March 20.

To the Secretaries of the National Association of General Practitioners, &c.

GENTLEMEN,—The Council of the Royal College of Surgeons of England have the honour to acknowledge your letter of the 20th of March.

It exhibits, first, a resolution of the gentlemen styling themselves the National Association, viz.—“That the National Association records its solemn protest against the proceedings of the Council of the College of Surgeons, in obtaining, and in subsequently carrying out, the recent charter, whereby a few gentlemen have been arbitrarily elevated over the heads of others, previously their equals in professional rank, senior to many of them as members of the College, and not inferior to most of them in scientific and practical knowledge.”

It next recites three questions, viz. :—First—“Is the Council of the College prepared to reconsider their charter, and to place those members who were in practice before it was granted on a level with the fellows ?”

Second—“Is the Council of the College disposed to admit to its board a fair representation of the members of the college in general practice ?”

Third—“Would the Council of the College be willing to co-operate with the National Association of General Practitioners in the formation of a Court of Examiners in medicine, surgery, and midwifery ?”

And the letter states, lastly, that “as a further duty has now devolved upon the committee, by a resolution of the general meeting, ‘to use every practicable means to obtain a charter of incorporation for the general practitioners,’ they are desirous to ascertain how far, and in what manner, the Council of the College of Surgeons may be disposed to assist the National Association in the attainment of its object.”

Such is the substance of the communications addressed to the Council of the Royal College of Surgeons, and though they might claim exemption from replying to propositions which can only legitimately emanate from the whole body, or at least from a majority of the practitioners, whose interests are involved, they willingly forego this plea, however valid, in finding connected with the National Association many members of the College, whom they individually esteem, and

in deference to the highly respectable class from which the Association has been formed.

In noticing the protest of the National Association, the Council have to remark, that the formation of the new class of fellows was an obligation imposed upon them by Her Majesty's Government, for the purpose of providing an electoral body. The principles on which they acted, in conformity with the provisions of the recent charter to that effect, are sufficiently explained in the following paragraphs, quoted from a statement, dated May 25th, 1844, which was circulated among the members:—"The Council entered on the duty assigned to them by the provisions of the charter, with a full sense of its invidious nature. They were aware that of those not included in the list of fellows a considerable number would feel and express dissatisfaction. But they have done what was required of them to the best of their ability, and have made the selection altogether on public grounds, without favour or prejudice, and uninfluenced by private motives. The great majority of the members of this College are less engaged in the practice of surgery than in that of medicine, midwifery, and pharmacy, and many of them have arrived at well-deserved eminence in these latter departments of the medical profession. But the Council, keeping in view the objects for which the College was especially established, have felt it their duty, in the nomination of fellows, to regard chiefly the qualifications of members as practitioners in surgery, or as improvers of those sciences which tend to its advancement."

Thus was the principle which guided the Council in discharging this responsible duty, publicly proposed and submitted to the opinion of the members of the college, whilst the power of nomination still remained; and the principle unhesitatingly avowed by the Council as that upon which they acted, and upon which they feel bound to act, were they entrusted with the office of reconstructing the schedule of fellows, is that of the selection of those who have distinguished themselves by the cultivation of surgery and its collateral sciences.

If, then, the first question which the National Association proposes has reference to a reconsideration of the charter recently granted exclusively for the purpose of placing all the members who were in practice before it was granted on the list of fellows, or, in other words of the letter, "on a level with the fellows," the Council earnestly protest against the scheme as essentially contravening the principle which they deemed it their duty to adopt; and they profess themselves unable to understand the grounds of a proposal which, in their deliberate judgment, would, by the lavish and indiscriminate grant of the fellowship, effectually destroy a distinction

which, if conferred on all, would be no distinction, and could confer no honour on the individual possessor.

It is true, indeed, that the alleged injustice of elevating a limited number of the members to a higher professional rank than their colleagues, would have been obviated, and that the 12,000 or 14,000 members who might thus have been created fellows would nominally possess a superior grade to those members admitted subsequently to September 1843; but it is equally plain that these newly created fellows would not have obtained their rank by any authorized claim to superior surgical attainments, since their qualifications could only have been tested by examinations, which always have been, and must ever be, conducted on the principle imperiously demanded by the needs of society—namely, that the majority of surgical practitioners shall be required to possess at least, but not necessarily more than that amount of information and skill which is absolutely required for the ordinary exigencies of surgical ministrations.

The Council, therefore, under a sense of justice to their future members, who will possess the same qualification as the present members, and under the obligation which the institution of the novel honorary degree imposed, necessarily sought other evidence of distinguished surgical attainments than the ordinary diploma, which attests only the amount of proficiency required of all. And those who feel disappointment would do well to bear in mind that they have been deprived of no privileges nor corporate rights, which they acquired, or hoped to possess, in becoming members of the college. They will recollect that in applying for their diploma they were not compelled to do so by any legal enactment, as they would have had an equal right to practise surgery without it, and they will probably admit that their sole inducement was that of obtaining in the diploma a testimonial to which the names of some of the principal hospital surgeons and teachers were appended. And let them not forget that one of the first acts of the college was to make a by-law, which was sanctioned by the proper authorities, excluding practitioners in pharmacy and midwifery from the governing body of the college, that they obtained their diploma under this known condition, and that they actually signed this and other by-laws, and swore to observe them.

It has been said and reiterated, as it is intimated in the protest of the Association, that the omission from the list of fellows implies professional degradation; the Council, however, cannot but think this feeling is grounded on a misconception of the nature of the qualification for the fellowship, already explained. Many of those who have not

been included in the list of fellows are well known to have attained the highest eminence, and to enjoy the highest reputation as practitioners in other departments of the profession; and the Council cannot believe that the interests, personal and professional, of members, can be injuriously affected, or their merits lowered in the estimation of the neighbourhood in which they reside, by the vicinity of those nominated as fellows, since the fellowship is simply an attestation of the surgical reputation, which they already possessed; and this distinction will be in a great degree effaced by the provisions of the medical bill now under the consideration of the legislature; since, in conformity therewith, every member of the college may, if he please, be registered as a surgeon, whether he be in general practice or not, and may thus be presented to the public in the same list and under the same title with the President, Councillors, and other Fellows of the College.

The Council deeply regret that their motives should have been misconstrued, and that so many of the members of the college should disapprove of their proceedings, but they trust that a dispassionate reconsideration of the subject will not fail to convince the Association that it would be difficult, if not impossible, to form a class of Fellows, in which the requisite respectability of the class should be preserved, without adopting a principle of selection no less invidious than that which has drawn so much obloquy on the Council. It has been contended, and the principle has been more than once agitated in the discussions in the Council, that the senior members admitted antecedently to a given date should form wholly or in part the list of fellows. But where was the line to be drawn that would have been satisfactory to those excluded?

It has been also proposed, that as vacancies occurred, the places might be supplied until all the members admitted before September, 1843, had been placed in succession on the list of fellows. But it behoves those who contend for any mode of forming a list upon the simple principle of seniority without selection, and still more those who urge the indiscriminate admission of all members to the fellowship, to weigh well the insurmountable objections to their scheme. Would they include those who have violated the laws of their country? Would they include professional paupers, and persons of notoriously bad character? Would they include the puffers and vendors of nostrums and secret remedies, and the writers of indecent advertisements? Would they include surgeons' assistants, or those who have connected themselves in business with druggists and chymists? Would they include the retail shopkeepers, who expose for sale cattle-drugs

and perfumery? Would they, finally, include or exclude all those who keep open shops, and who, though ill sustaining a professional character, are yet not chargeable with any moral disqualification? In short, would the National Association, in conformity with their views, advise admitting all such as members of the proposed college of general practitioners, without discrimination or selection, merely because they are members of the College of Surgeons, or licentiates of the Apothecaries' Company?

These are grave questions, which cannot be dismissed by a simple negative or affirmative, and would require for their solution nicer distinction than the Association seems to have anticipated; and, on second thoughts, the Association may perhaps forgive the Council for ridding themselves of the difficulties attendant on the investigation of comparative respectability, by adopting a surgical qualification, and this only. And the Council firmly trust that the formation of a class of fellows, selected, in the first instance, for their character as accomplished surgeons, and its dignity maintained and perpetuated by the admission only of persons of higher education and extended experience, will, without fail, increase the estimation of surgeons generally, and no less of every member of the college.

In respect to the second question—viz. "Is the Council of the College disposed to admit to its board a fair representation of the members of the college in general practice?" the Council beg to remind the National Association that the College of Surgeons is not, and never was intended to be, a college of general practitioners; and that the members of the college, under whatever denomination, have no other recognised connexion with the college than as surgeons. The College of Surgeons is strictly an institution for the promotion of surgery, practical and scientific, and for testing the qualifications of those who intend to practise surgery. It is true, that, under the existing arrangements of the medical profession in this country, the majority of its members are and will be general practitioners: it is true, also, that many of the provincial hospital surgeons, though practising the other branches of the profession, have eminently distinguished themselves by their scientific cultivation of surgery; but it will scarcely be doubted that the greater number of those who conjoin with the practice of surgery that of medicine, pharmacy, and midwifery, from the multifarious nature of their pursuits, and from the unceasing demand upon their time and attention in their laborious and responsible avocations, will probably want the opportunities and inducements which are required for the special cultivation of surgery, and will scarcely be found to possess the quali-

fications for regulating the education of surgeons, and for promoting the great public objects for which the college was founded.

The third question, viz.: "Would the Council of the College be willing to co-operate with the National Association of general practitioners, in the formation of a Court of Examiners in medicine, surgery, and midwifery," was probably intended to stand thus:—would the Council of the College be willing to co-operate with the proposed new Corporation of general practitioners, in the formation of a Court of Examiners in medicine, surgery, and midwifery? The Council, then, understanding this to be a proposal for forming a joint board of physicians, surgeons, obstetricians, and pharmacists, for the examination of general practitioners, have to express their readiness to submit to the enactments of the Legislature, or to the regulations of the Council of Health, but they cannot but anticipate the inconvenience that would result from carrying on the examinations on anatomy, medicine, surgery, midwifery, and pharmacy at one board, and at one sitting, instead of distributing the subjects into distinct examinations; and they believe so protracted and multifarious a demand upon the mind of the candidate would be calculated to perplex and bewilder even the best-informed student.

If, however, the aim of the Association be, when explicitly stated, that general practitioners are to be eligible to, or to constitute at all times a certain proportion of, the Court of Examiners of the College, the Council are bound to reply to the third as to the second question, and to state their unqualified conviction that the proposal of converting the College of Surgeons into a college of general practitioners; or depriving the college of its distinctive character and office, and of substituting for these a medley of function, each of which requires for its performance its duly qualified functionaries; that the proposal of merging the College of Surgeons in a college of practitioners in medicine, surgery, pharmacy, and midwifery, would defeat the very object for which the college was instituted, and would go far to deprive the country of the best and perhaps the only mode of maintaining the efficiency of the surgical department of the profession. And if the class hitherto existing of teachers of anatomy and surgery is to be preserved; and the council cannot believe that the Association has forgotten its paramount claims to public patronage and protection; if the interest alike of the profession and country point out the necessity of fostering a class of men devoted to the absorbing pursuits of science, without whom, indeed, the very sources of professional knowledge would be dried up; if adequate encouragement is

to be given to the long, toilsome, and self-denying preparation for the offices of lecturers and surgeons of hospitals, under circumstance in which the prizes are few and the reward distant and uncertain,—it is scarcely too much to expect that the seats to the Council and in the Court of Examiners should be reserved for those whose habits and pursuits best fit them for the duties which an institution for the promotion of scientific surgery implies.

Lastly, with regard to the proposed incorporation of the general practitioners, as a separate body or college, the Council have as little the wish as the power to prevent them from obtaining a charter, and would offer no objection to the incorporation of a body for the performance of the functions hitherto executed by the Society of Apothecaries; but, actuated as the Council are by the desire of promoting the usefulness and respectability of the general practitioners, they dare not, consistently with their sense of duty to the profession, and with their regard for the interests of the general practitioners themselves, hold out any hope of co-operation with the National Association in a plan for instituting a corporation which would supersede the defined and recognised functions of the existing College of Surgeons.

And they entreat the Association to bear in mind that by the provisions of the recent charter, and of the bye-laws of the college in conformity therewith, the union of general practitioners with the college will in future be attained by means which cannot fail to raise their qualifications and to promote their respectability. The fellow of the College who had obtained his degree at 25 years of age, after a liberal and extended education, will not be precluded from practising, in conjunction with surgery, the other branches of the profession; and a general practitioner, who may have been deprived of the opportunity of obtaining his degree at 25, may become a fellow, after a definite number of years of practice.

That many, or all, the members of the college, will take advantage of these opportunities of honourable distinction, is the sincere hope of the Council! And in tendering their best wishes for the welfare and increased respectability of the general practitioners, they take leave to express their conviction that the claim which they fearlessly urge to disinterested motives, and a deep sense of their responsibility in the government of the college, will be cheerfully accorded in calmer times by an enlightened profession.—I have the honour to be, gentlemen, your most obedient servant,

E. BELFOUR, Sec.

Royal College of Surgeons of England,
3d of April.

[We wish we could say that the answer

returned by the Council of the College to the appeal here made to them was satisfactory. With the list of "Fellows" before them, it surprises us to find the Council asserting, that in the "institution of the novel honorary degree" they "necessarily sought other evidence of *distinguished surgical attainments* (!) than the ordinary diploma, which attests only the amount of proficiency required of all." Among the "Fellows" are some whose names had never been heard of in the profession before—members with diplomas of a few years' standing, the pupils of some who were excluded, and whose only ostensible title to the honour appeared to be, that on such a day in such a year, they accidentally occupied the office of assistant-surgeon or demonstrator of anatomy in some provincial hospital or infirmary, &c. If the College had done as it professes, *i. e.* have taken only "*distinguished surgical attainments*" as the qualification for the fellowship, there would not have been the present outcry in the shape of complaint or remonstrance, which, judging by the very numerous letters we have received, proceeds as much from fellows of the College (to their credit be it spoken) as from general practitioners. The Council may, if they please, easily extricate themselves from their difficulty, without admitting as fellows, men who have been guilty of felony—quack-surgeons—surgeon-chemists and druggists—surgeon-shopkeepers, &c. To oppose this a difficulty to the admission of many highly respectable and worthy members, as fellows, is a mere pretence for the denial of justice. By excluding a class of unworthy members, they may undoubtedly create dissatisfaction among them; but is this a reason for allowing the present just cause of discontent to prevail among a large majority of the respectable members of the College, who do not fall under any one of the denominations mentioned? We think not. The answer simply amounts to this: There are some of you who are unworthy of the fellowship; and therefore we will admit none. It is not considered, that the same objection would have applied with equal force to a large number of those whose names have been arbitrarily placed on the list of fellows.—*ED. GAZ.*

PROPOSED CHARTER
OF THE
ROYAL COLLEGE OF PHYSICIANS
OF ENGLAND.

*Statement regarding the Licentiates
extra Urbem.*

SIR James Graham having announced her Majesty's intention of extending the jurisdiction of the Royal College of Physicians in London over England and Wales, and of constituting it the College of Physicians of

England, it has become of importance to the *permissi extra urbem* of that College to inquire what are their existing rights and privileges, and how far those rights may be affected by the proposed charter.

The powers of the College of Physicians of London are derived from the Act of the 14th and 15th of Henry VIII. By this statute it was ordained, "that no person from henceforth be suffered to exercise or practise in physic, until such time as he has been examined in London by the president and three of the said elects, except he be a graduate of Oxford or Cambridge, which hath accomplished all things for his form without any grace." By the same Act, the jurisdiction of the college in London and within seven miles thereof (granted by charter four years before) was confirmed. The two classes are therefore equally ancient, and have equal privileges within their respective limits; but as the common seal of the college is not appended to the letters testimonial of the *extra urbem* licentiates, they are, in common with the graduates of Oxford and Cambridge, excluded from practice within the metropolitan boundary. On the other hand, it is equally manifest that as the *intra urbem* licentiates are not examined by the president and elects, as expressly required by the Act, but by the president and censors, their letters testimonial have no legal force throughout England.

It thus appears that the statute rights of the *extra urbem* licentiates are precisely equal to those of the *intra urbem* licentiates, and of the graduates of Oxford and Cambridge; that they are the only physicians practising throughout England (London excepted) created by the letters testimonial of the college; and that they have always been independent of its jurisdiction. It follows, then, that if that jurisdiction be extended by charter over England, the *permissi extra urbem*, if they have not a fair claim to constitute the commonalty of the proposed College of Physicians of England, have at least an undeniable claim to incorporation with the *permissi intra urbem* on equal terms.

It may be objected, that there are *permissi extra urbem* who are not graduates in medicine. But this objection is altogether futile; for the law of England has never recognized that degree as of itself constituting the legal qualification to practise. Even medical graduates of Oxford and Cambridge are required by the statutes of those Universities to be examined for a license *ad practicandum*; and it is by this license that they are authorised to practise "*per totum regnum Angliæ*." The college itself has always acted on the principle that the license alone creates the physician, by invariably requiring all candidates, whether graduates or not, to submit to an examination.

Nor is the claim of the *permissi extra urbem* to an equality of rights in the proposed new charter with the *permissi intra urbem*, invalidated by the fact that the latter have paid a larger sum for their license, for they have value received in the monopoly of metropolitan practice they enjoy, and in the exclusive use of the college, and its museum and library. If the *permissi extra urbem* be admitted to a share in both, they should only be called upon for an additional payment when, by a residence in the metropolis, they will be in a position to avail themselves of those privileges.

Neither can this claim be resisted on any fancied grounds of superiority on the part of the *intra urbem* licentiates. It is true that the latter are examined by a different board; the curriculum of study is, however, the same for both, and the *extra* licentiates are examined by the highest authorities of the college, namely, by the president and the president elects. It would, indeed, be a monstrous libel on the president and his colleagues, (they being, according to the charter, "the most cunning and expert of the faculty in London," (to suppose such dereliction of duty on their part, as would be implied in the insinuation that the professional qualifications of the *permissi extra urbem* are inferior to those of the *permissi intra urbem*.

For these reasons, then, the *permissi extra urbem* demand that they be subjected by the new charter only to such regulations and the payment of such fees as may be required of the *permissi intra urbem*.

Extra licentiates of the college, desirous to co-operate in obtaining these objects, are requested to communicate their names forthwith to one of the following gentlemen:—Dr. Clay, Manchester; Dr. Davies, Hertford; Dr. Hitch, Gloucester; Dr. Laycock, York.

ROYAL SOCIETY,

Saturday, April 5.

THE last Soirée of the Royal Society for the season took place on Saturday last, at the house of the noble President. It was attended by a large number of noblemen and gentlemen, including nearly all who have acquired any celebrity in literature, science, and art. The members of the medical profession were very numerous. Among the scientific discoveries which were made subjects of illustration was the newly-invented art of Anastatic printing, of which, so far as it depends on chemical principles, we here give a brief description. The whole of the process was carried on in one of the rooms, and painted sheets, which would have taken a considerable time for composition, were transferred to zinc, and perfect im-

pressions drawn from them in an incredibly short period. The art itself is essentially founded on chemical principles, and applies to the copying of all documents in which oil is the basis of the ink used. The printed sheet or engraving to be copied is sponged with nitric acid diluted with eight parts of water: it is then pressed in folds of blotting paper, and deprived of nearly the whole of its moisture. When nearly dry, it is placed with its printed face downwards on a clean surface of luminated zinc, and submitted to very powerful pressure in a roller press. The pressure is so great, that the layer of zinc becomes curved by the process. The surface of the zinc is acted upon by the diluted nitric acid, and finely corroded in all those parts, corresponding to the unprinted portions of the sheet, the oil preventing the inhibition of the acid in the printed parts. This leaves on the zinc an embossed or slightly raised copy of the whole of the printed letters or engraving. A liquid (said to be mucilaginous) is then rubbed over the plate; this soaks into the porous or corroded parts, and leaves the raised portion, which afterwards receives printers' ink from a roller in the usual way, and then yields impressions as if it were a closely set mass of type. The pressure would speedily lead to the obliteration of the raised metallic letters, but for the occasional application of another liquid (described as a mixture of phosphorous and phosphoric acids), which is stated to remove the zinc from the already corroded portion of the plate.

The most remarkable part of this discovery is, that a printed page nearly effaced and illegible may be made to yield a perfectly clear and distinct copy. This depends on the fact that it is the oil in the printed paper which excludes the diluted acid; so that if a page were printed with colourless oil, the action on the plate would be the same.

Among other subjects of interest were two of Ross's microscopes, in one of which was exhibited metallic copper crystallized in tetrahedra, and procured by the following singular process. Glass, coloured by oxide of copper, was melted, and then stirred with an iron rod; the copper was thus separated in the metallic state, and became crystallized during its separation. The iron is converted to peroxide, which gives no colour to glass unless it be present in very considerable quantity.

An apparatus for carving artificial palates, with teeth, in ivory, was also exhibited. A model of the palate is taken in wax, and from this a composition mould is afterwards procured in the usual way, and fixed in the machine. It is impossible, in a short space, to give a description of this ingenious apparatus—the invention of Mr. Tomes, but the principle on which it acts is some-

what similar to that of the anaglyphographic or medallion engraving. A facsimile of the palate is thus taken in ivory. Some palates in ivory were shewn which exhibited all the minute elevations and depressions of the natural palate, and indeed, but for the colour of the material, might have been mistaken for it. This invention may ultimately have some important surgical applications.

DR. THEODORE GORDON.

SCIENCE and humanity have to deplore the loss of this able physician and most excellent man; he died at Brighton, whither he had gone in the hope of recruiting his strength, on the 30th ultimo, in the 59th year of his age.

Dr. Gordon was a native of the north of Scotland, and descended of a good if not a very wealthy family. He received the rudiments of his classical and professional education in Aberdeen, and subsequently went to Edinburgh, where he attended the lectures of Monro, Gregory, Rutherford, and the other eminent professors of that distinguished medical school. In the autumn of 1803 Dr. Gordon entered the army; and in the following year, as Assistant-Surgeon to the 91st Foot, he served abroad, first in Hanover, and then in Portugal, where he was present at the battles of Rolicca and Vimiera, and narrowly escaped with his life when cast away in the river Douro. Appointed Surgeon to the 89th Foot in 1809, he was present at the unfortunate affair of Fuengerola, under Lord Blaney. With the 4th Foot, or King's Own, into which he exchanged in 1811, he served in Ceuta, in Africa, and was one of the Commission for the cession of that fortress to Spain. Whilst stationed in Ceuta he again narrowly escaped with his life, having fallen into the hands of the Moors while out with his gun; he got off with a sound beating, however, for a dog of a Christian as he was. Ceuta abandoned by the British, Dr. Gordon accompanied his regiment back to the Peninsula, and had the honour of accompanying the Duke of Wellington through a large portion of his career of victory, having been present at the battle of Salamanca, in the retreat from Burgos, the battle of Vittoria, the siege of St. Sebastian, and the passage of the Bidassoa, in which last affair, while in medical charge of the 5th Division, he was severely wounded in the head and neck.

In 1813 Dr. Gordon was appointed Surgeon to the Forces, and had charge of York Hospital. In 1815 he was again engaged in foreign service; and at Brussels, after the battle of Waterloo, had the superintendence of the French wounded. He accompanied

the advance on Paris, and in that city had charge of the military hospital of St. Louis. Promoted to the rank of Physician to the Forces in the autumn of 1815, in the beginning of 1816 he was appointed Professional Assistant in the Army Medical Board Office, the arduous and important duties of which he continued to perform until within a few weeks of his death.

Dr. Gordon's long and able services were finally crowned, in 1818, by the Deputy Inspector-Generalship of Hospitals, which was the highest rank he attained.

Dr. Gordon's life was one of action, not of meditation or closet study; he has therefore left little in the shape of writing by which the world at large or posterity can judge of him as a medical man. Those who knew Dr. Gordon most intimately, however, appreciated his abilities most highly; he had a keen eye for the discrimination of disease, and what art could do to bring relief, he had always at hand. It was as a man, as a friend, however, that Dr. Gordon engaged the largest portion of the sympathies and affections of his contemporaries. Probably no man ever lived who had a larger and more attached circle of friends than himself; he was trusted, beloved, honoured, by all who knew him. His judgment in the affairs of life was eminently clear and practical; his disposition was at once open, kindly, generous; one of the warmest and most faithful of friends, he may truly be said to have passed through life without having had an enemy!

Dr. Gordon had laboured under an affection of the heart for more than twenty years before his death; he always believed himself that he should die of this disease. He did not prophesy truly of the cause of his end, however; for an attack of bronchitis, dependent in all probability on the presence of tubercles in the lungs, was followed by an accession of acute dysentery, which never ceased until it had worn him out. He was attended in his last illness, with the greatest devotion, by his old friend, Mr. Johnson, Surgeon-Major, late of the Grenadier Guards, and by Dr. James H. Pickford, late Assistant-Surgeon in the same corps; and was also visited three times a week by his attached friends, Sir James Clark and Dr. Willis. The attack had a formidable aspect from the first, however, and all who saw him feared for the issue.

On a post-mortem examination, which was performed by Dr. Pickford, extensive tubercular depositions were found in both lungs; the heart was greatly enlarged, particularly on the right side, extremely thin in its walls, and soft in its substance; the large intestines were covered, from the caput coli downwards, with extensive and deep ulcers.

MEDICAL INTELLIGENCE.

WE have been informed that the bill for regulating the medical profession will be brought into the House of Commons on Monday next, the 14th instant.

DISCHARGE OF A LUMBRICUS FROM THE MALE URETHRA.

DR. PETER F. CLARK has recorded in the *New York Journal of Medicine*, (May 1844,) a case in which a lumbricus teres eleven inches long was discharged from the urethra of a man thirty-three years of age. Dr. C. thinks that eighteen months previously, at which time the patient laboured under symptoms of disease of the bladder, a communication was formed by ulceration between that organ and a contiguous surface of intestine, through which the worm had passed from the latter into the former organ.—*American Journal of the Medical Sciences*.

EXAMINERSHIPS ON CHEMISTRY IN THE UNIVERSITY OF LONDON.

PROFESSOR BRANDE has been appointed to the Examinership on Chemistry, vacant by the death of Professor Daniell, so far as regards Medicine, and Professor Graham, of University College, has been appointed to the Examinership of Chemistry in Arts.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

List of Gentlemen admitted Members, April 4.—R. Ripley.—E. D. Rudge.—R. Tiffin.—J. W. H. Mackenzie.—W. R. S. Lane.—W. H. Pilkington.—J. A. Elliott.—E. Lawes.—P. Jones.—T. Wright.

APOTHECARIES' HALL.

Gentlemen who have obtained Certificates, April 3.—W. D. Wathen, St. David's, Pembrokehire.—F. Fitch, Sudbury.—R. T. Cobbold, Saxmundham.—T. H. Watt, Deal, Kent.—W. Westall.—C. G. Mott, Derby.—J. Bromfield, Whitchurch, Salop.—E. Noyce, London.

NOTICES TO CORRESPONDENTS.

WE shall be glad to hear again from Mr. R. H. Meade, of Bradford, Yorkshire. His Clinical Observations will be inserted next week.

If Δ can furnish us with any cases in which his plan of treating diabetes has succeeded, we will give them insertion.

The Memoir of the late Dr. Heberden will be inserted.

"A Subscriber" will perceive from our leading article, that "a licentiate" may assume the title of "surgeon" (as the bill at present stands), although he cannot be registered as such.

Received—Cases by Mr. Collier; the

Hereford Memorial; "Lector;" "A Practitioner;" the Wolverhampton Petition; the Liverpool Resolutions.

We regret that we cannot notice the circumstances to which Vindex refers. Dr. F. need be under no apprehension of an attack in the Mesmeric Magazine affecting him in the opinion of the profession. The journal only finds circulation among the class of impostors who record their own doings in it.

MORTALITY OF THE METROPOLIS.

Deaths from all causes registered in the week ending Saturday, March 29.

ALL CAUSES	1188
SPECIFIED CAUSES	1182
I.—Zymotic (Epidemic, Endemic, and Contagious) Diseases, 195; among which, of—	
Small Pox	32
Measles	30
Scarlatina	30
Hooping Cough	37
Croup	7
Thrush	5
Diarrhoea	12
Dysentery	1
Cholera	1
Influenza	3
Typhus	31
II.—Dropsy, Cancer, and other Diseases of uncertain or variable Seat, 115; among which, of—	
Hæmorrhage	3
Dropsy	30
Scrofula	4
Cancer	11
Atrophy	20
Debility	13
Sudden Deaths	23
III.—Diseases of the Brain, Spinal Marrow, Nerves, and Senses, 197; among which, of—	
Hydrocephalus	42
Apoplexy	32
Paralysis	34
Convulsions	63
Insanity	3
Delirium Tremens	0
IV.—Diseases of the Lungs, and of the other Organs of Respiration, 396; among which, of	
Pneumonia	104
Hydrothorax	9
Asthma	43
Phthisis or Consumption	164
Diseases of the Lungs, &c.	21
V.—Diseases of Heart and Blood-vessels	47
VI.—Diseases of the Stomach, Liver, and other Organs of Digestion, 71; among which, of—	
Teething	19
Gastritis	1
Enteritis	13
Tabes	4
Hernia	0
Disease of Stomach, &c.	3
Disease of Liver, &c.	11
VII.—Diseases of the Kidneys, &c.	7
VIII.—Childbirth, Diseases of the Uterus, &c. 12; among which, of—	
Childbirth	10
Disease of Uterus	1

Medicine and the Collateral Sciences.

FRIDAY, APRIL 18, 1845.

LECTURES
ON THE
NATURE AND TREATMENT OF
DEFORMITIES,

*Delivered at the Royal Orthopædic Hospital,
Bloomsbury Square,*

By R. W. TAMPLIN, F.R.C.S.E.
Surgeon to the Hospital.

*Angular curvature of the spine — Pott's
disease: Nature of—Treatment. Treat-
ment of angular curvature of the spine.*

I MUST now draw your attention to angular curvature of the spine, of which an immense number of cases present themselves at this Charity. This deformity arises from disease and ulceration of the bodies of the vertebræ, for the true knowledge of which we are indebted to the late Mr. Pott; and as the deformity is, generally speaking, the first thing which attracts the attention of the parents or friends of the patient, and also that which induces them to apply for relief, a large proportion of cases attending here are suffering from active disease, as well as the curvature consequent upon it: it becomes therefore necessary that I should briefly allude to it. This affection, then, consists of ulceration of the body or bodies of one or more vertebræ, and is found to attack any portion of the spine from the atlas to the sacrum; most frequently the dorsal vertebræ; secondly, the lumbar; and lastly, the cervical. It generally occurs in weak and unhealthy children, who are already predisposed, from any slight casualty, to diseased action. Not unfrequently it is combined with the tubercular diathesis, which will be found occasionally in the active stage; and in all instances that peculiar condition called "strumous" is but too evident. The strumous and tubercular, however, to my mind, differ but little from each other.

The first circumstance, then, that attracts
907.—xxxv.

attention, and for which you will be consulted, is a projection in one or other of the situations mentioned, sometimes so slight as scarcely to attract attention, and without any external evidence of disease beyond the simple projection. This projection, however, when the result of disease and loss of substance of the bodies of the vertebræ, is *always* angular; from which fact it may be at all times recognised, even in this its most incipient state, and by which it may be distinguished from the posterior curvature of the spine common in children, but which exists without any disease affecting the vertebræ. It is of great importance that you should distinguish the one from the other, especially in the incipient stage, as by so doing a stop may be put to the progress of the ulceration, and of course deformity, as well as the serious consequences attending its progress altogether prevented. As the ulceration proceeds, the angle increases, and becomes more or less acute, according to the number of the vertebræ affected, and the loss of substance sustained. The spine being no longer capable of bearing the superincumbent weight of the head and shoulders, an additional source of irritation is thus mechanically brought into operation, which not only increases the amount of the deformity, but also that of the disease itself,—an important fact to be borne in mind in the treatment, as I shall presently point out to you. In the commencement of this affection the patient suffers very little pain—at all times some—which is characterised by an occasional scream and general restlessness, not sufficiently defined to attract attention to the spot. As it proceeds, however, the pain becomes more severe, and is increased upon motion of any kind; and as it is scarcely possible for the spine to be kept at rest by the efforts of the patient or friends simply, in many instances, the general health suffers from the constant irritation thus kept up, the appetite fails, the bowels are irregular, the secretions unhealthy, and, unless relief is

obtained, hectic supervenes, abscesses form, and death puts a period to their existence. As the ulceration affects the anterior surfaces of the bodies of the vertebrae, of course it is in this situation that the matter is formed in cases of abscess, the existence of which is generally indicated by an enlargement and thickening on each side of the projection, as well as above and below it, and also by the increased disturbance in the general health. As the matter increases in quantity, it descends, principally by gravitation, behind the fascia into the pelvic cavity, and not unfrequently presents itself on the anterior and internal surface of the thigh, below the insertion of the psoas and iliacus muscles, having been confined in its course by the fascia covering them. At other times it does not proceed so far down, but will present itself in the loins; several cases of which have lately occurred. The matter thus secreted amounts oftentimes to an incredibly large amount, and, after the active symptoms occasioned by its first onset have subsided, produces very little irritation. A patient was admitted some time since with angular curvature affecting the dorsal vertebrae, in a girl aged about 5 years, whose general health was at that time very good. She remained in the house about three or four months, and was during that time kept in the horizontal position, with a support to the back, which prevented any motion taking place in the spinal column. The child continued in good health and spirits, and the projection was certainly less acute. I ordered that she should be placed on an inclined plane during the day, with a view of diminishing the angle so far as the compressed intervertebral substance would admit of, immediately above and below the angle. This was accordingly done. On the third day the nurse drew my attention to a general enlargement of the left thigh. I examined it, and believed that I could distinguish a sense of fluctuation. There was no pain occasioned by the examination, neither had the child complained previously. On the fourth day the thigh was inflamed throughout its entire extent, and the cellular tissue became somewhat indurated. Several gentlemen saw the patient, some agreeing with me in opinion of there being matter, others differing, regarding it as inflammation of cellular tissue alone. I then ordered fomentations, poultices, and bandages, and in a week the redness subsided, but not the swelling of the thigh. In about a month afterwards a projection was noticed in the situation of the left loin, which continued to increase, and at once proved that the cause of the swelling was the existence of a lumbar abscess, and which had been forming for some time previous to her admission; for from the time of her entering the hospital up

to this period her health had been uninterruptedly good. The collection of matter had, however, slowly increased, and was first indicated by the change from the horizontal to the inclined position, the matter gravitating down, and appearing in the thigh. After the horizontal position was resumed the swelling in the thigh diminished, and the abscess pointed in the lumbar region.

Another case similar to the above occurred a short time since. A child, about 4 years old, had been attending as an out-patient for some months, and appeared to improve in health and strength. She was wearing a support, which I shall presently shew to you, and got about without any apparent inconvenience. However, on one occasion, her mother stated that the instrument had made her back swell. Upon examination I found a projection in the loin, indicating the existence of a lumbar abscess; so that it appears that after the active symptoms have subsided, the collection of matter still goes on, the evidence of which we are totally at a loss to discover, until it presents itself in one or other of the situations mentioned; and, as in the cases just now related, apparent improvement may continue for months with this serious addition to the original disease. You cannot, therefore, be too cautious in expressing an opinion upon these cases.

In some instances paralysis of both lower extremities will be found to coexist: this circumstance is not occasioned by the curvature of the spine, for in the most severe curvature that can be met with the functions of the spinal marrow are not interrupted, or in any way impaired, but by pressure occasioned either by inflammation of the chord and effusion as a consequence, or by the pressure occasioned by a collection of matter, with the entire obliteration of one of the bodies of the vertebrae.

If the integrity of the canal is preserved, which it generally is, and the inflammation is not propagated to its investing membrane, no matter how acute the curvature or angle at which the spine may be, the spinal marrow adapts itself to the change of position without any interruption to its normal functions; instances of which may be found in every museum. What is the cause that first set this disease in operation? Some have assigned a specific cause, as disease of one or more of the bodies of the vertebrae; I am at a loss to imagine this, as there is nothing that I can discover specific about it; there is simply inflammation and ulceration of the bones, similar to that which is witnessed in the neighbourhood of the hip and knee-joint most commonly, at times also in the elbow and wrist-joint. In these instances a blow or fall, or some injury, has preceded the diseased action, and to which

the friends assign it. In this particular instance invariably the cause assigned is a fall or other injury, and I certainly am of opinion that it is brought into operation by some mechanical injury; although we must admit that these patients are predisposed to diseased action either constitutionally, or from general and excessive debility. There is rarely any activity evinced in the most severe cases from the commencement to the termination of the disease, which arises from a general want of power, and the consequent inability that exists for the restorative efforts either to put a stop to or to control the diseased action, until an improvement has taken place in the general health, which improvement it is at times difficult to bring about; and it must be borne in mind that a slight and almost imperceptible injury is sufficient to set up diseased action, in whatever part it may happen to be applied. There does not appear, therefore, to be the capability of resisting diseased action, provided that the part or parts are subjected to the slightest interruption in the performance of their functions. These patients, however, present oftentimes the appearances of health, and upon inquiry their relatives will inform you not only that they were in good health, but that they had not suffered previously. This is no proof against the supposition that there is a predisposition to disease, inasmuch as a state of apparent health is unfortunately consistent with the existence of mortal disease—as is witnessed in cancer, and other malignant affections.

Treatment.—From what I have said you will perceive that the treatment of this disease resolves itself into general, local, and mechanical. As the constitution or general health is in all cases at fault, every means must be had recourse to which has for its object the improvement of the health of the patient, and it must be evident that tonics, attention to the diet, as well as to the secretions generally, will require the greatest perseverance, and also that *absolute* rest is indispensable.

The first thing to which you must direct your attention is that, of preventing any motion taking place in the spinal column beyond that which is almost unavoidable, and the most effectual means of accomplishing this object is to place the child either on its back or face, in the horizontal or inclined position, or both—the plan adopted by the late Dr. Verrall (the inclined position on the face). On no consideration ought the patients to be allowed to place themselves in such a position that the weight of the upper portion of the body shall press, and therefore irritate the existing disease: during the active stage, as well as during the first efforts of restoration, this point must be made a *sine qua non*, for without it all other means are of necessity

abortive: no one would for a moment allow any mechanical irritant to press upon an external wound, neither is any one to be found who would justify such a proceeding, or scarcely believe it if they saw it; and yet this disease, which is placed in a similar circumstance from its seat and nature, is but too often subjected to the constant irritation, from want of proper attention to this point, and also might be added, to the serious mischief and consequences which so often result as a sequel to this affection.

The plan I usually adopt is the following: to request that the parents should obtain a board somewhat wider and longer than the patient; let a horse-hair mattress be placed upon it, and let two circular holes be made in it at the point corresponding with the axilla, in which can be inserted a couple of plugs (one for each side), when the patient is in the inclined position, to prevent them from slipping down. With this simple contrivance, which is within the reach of all, from the facility of obtaining it, a child may be kept at rest, the disease protected from pressure, and the angle relieved, or, at all events, any increase of it effectually prevented; whilst at the same time it is the greatest possible source of comfort to the patient, who, instead of becoming fretful and irritable, with the health suffering as a consequence, as might be anticipated from the confinement, actually improve in health, and are most completely relieved from pain.

The restorative process in disease of the bones, is, as I had occasion to remark when speaking of disease of the knee-joint, always slow from its very nature; therefore their treatment must be continued for some months; otherwise, whatever improvement may have taken place, the parts become easily irritated from the pressure occasioned by the erect posture: a relapse with increased mischief follows.

Counter-irritation was used with success by the late Mr. Pott, and its advantages have since been proved by the test of experience. I have found *mild* counter-irritation answer every purpose, without the risk of interfering with the child's health, or of adding to the irritation from which they already suffer; and the form I usually adopt is that of an ointment compounded of equal parts of the Emplastrum Lyttæ and Unguentum Hydrargyri, directing the attendant to rub the part on each side of the projection and above and below it, then to apply a soft linseed-meal poultice; this is generally followed by an eruption and redness without destroying the cuticle. I then direct that they should allow this irritation to subside before a fresh application is made, continuing, however, the use of the poultice, which very frequently keeps up sufficient irritation of itself: as soon as the irritation on the

surface has subsided, or nearly so, let the ointment be reapplied, and a similar course pursued as long as there is any evidence of active disease existing.

As this disease is essentially one of debility, or connected with it, the diet must be nourishing and slightly stimulant. Some object to stimulants; I have found them decidedly useful at times in giving tone to the stomach; especially where the appetite is bad and there is great depression, small quantities of port wine, or beer, are of great assistance. As it regards the tonic, that must be left to the discretion and experience of each individual; I prefer, as I have often stated to you, the preparations of iron. The bowels must of course be regulated, and if it becomes necessary to use aperients, let them be of the mildest form, merely to produce the effect without irritating or exhausting the patient: castor oil is as good a means as any, and one which I recommend to be given when necessary. Occasionally, when there is great constitutional irritation during the formation of matter, you will do well to allay it by an opiate at night, which can be given in conjunction with the Hydrargyri c. creta; and, should the bowels be relaxed, the Mistura Creta, with the Aromatic Confection, and a small quantity of the Tinct. of Opium, should be administered regularly until it is stopped: if, however, the general health is good, the appetite natural, I should not advise any interference, merely strict attention to the position. When paralysis of the lower extremities has come on, I have found it necessary to increase the local irritation, and to administer mercury in the form of the Hyd. c. Creta, regularly, and in some instances with success. Even in these cases a nourishing diet must still be continued, and the strength of the patient supported in every possible way. A patient is at this time attending whose lower extremities were completely paralysed—not a trace of motion could be discovered: by these means he is gradually recovering the lost power, which first returned in the muscles of the toes, then the feet and knees. The amount of power is still slight, but it is evidently increasing. I believe I have noticed the principal points in connection with this affection, and I shall now return to the deformity resulting from it, and existing after the subsidence of the diseased action, namely,

Angular curvature.—From the cause of this deformity, it must be evident that our efforts can only be directed to relieve, not to remove, this deformity, inasmuch as when once a loss of substance has taken place in the bodies of the vertebrae, it is not reproduced, at least in a very imperfect degree; therefore, to straighten the spine, which undoubtedly, in young subjects, could be done, would be to adopt a mode of practice

unscientific, and fit only to be pursued by charlatans and quacks, who have neither character or reputation at stake. If the deformity is very slight, and you have an opportunity of treating it immediately following, or very shortly after, the subsidence of the disease, you can effectually put a stop to any increase which must otherwise occur from the gradual compression of the intervertebral substance above and below the angle, by doing which it becomes of little moment, and, when cured, of no inconvenience, to the patient. If, on the contrary, the deformity is to any extent, and the patient young, the relief that can be *prudently* obtained is that only which is occasioned by the compressed intervertebral substance: this, at times, is of some amount, and, upon its being removed, reduces considerably the appearance of the deformity. The mechanical means I have adopted are similar to those which have been in use from time immemorial, namely, a support to the upper extremities, consisting of a band which encircles the pelvis, having attached two crutches, one on each side, to support the shoulders, the crutches consisting of a male and female screw, which enables me to increase their length, provided relief is obtained, as the child grows—*Vide* fig. 1. I then direct that a broad flannel band should be passed round the crutch on one or other side, and over the projecting vertebra, then round the opposite crutch back again to the commencement of the band, and there united: by this means an effectual support is given without encircling the abdomen. Of course this applies to curvature existing in the dorsal or lumbar vertebrae, and not to that which exists in the cervical vertebrae. In the latter instance I have used a support similar to that represented in fig. 1, having, in addition, a part to support the head alone, so that the pressure on the anterior surface of the vertebra is effectually prevented, as in this instrument [showing it]. The use of the support must be uninterruptedly continued for years, and for the first year at least it should be worn night and day, otherwise the deformity will increase, not so much from the original seat of the affection, but from compression kept up in the intervertebral substance. In older cases, where the deformity is severe, and the loss of substance considerable, no benefit can be expected from any treatment beyond that which is connected with the feelings of the patient. Where there is a great weakness, and inability to take much exercise without fatigue, a support similar to that represented is frequently of the greatest comfort and assistance; but recollect that it must be used only as a support, and not with a view of extending the spine forcibly. In fact, in all cases of this kind, this principle must be

FIG. 1.

Diagram of an Instrument for the relief of angular curvature, the description of which is given at page 916.

adopted, as force or violence of any kind can lead only to results which would be regretted. A case of a young man occurred, some time since, in the hands of the spinal empirics—alike ignorant of the cause as well as of the effect, at least it is charitable to think so—in whom violent force was had recourse to, with the removal of the deformity certainly, but at the cost of the sudden death of the patient as a consequence. Violence or brutal force, such as was used towards this unfortunate patient, cannot be too strongly deprecated.

APPENDIX TO THE ESSAY
ON
DISEASES OF THE NERVOUS
SYSTEM :

CONTAINING NOTES OF THE LECTURES OF
THE LATE PROFESSOR GREGORY,
OF EDINBURGH.

BY EDWARD BLACKMORE, M.D. Edinb. •
Member Extraordinary of the Royal Medical
Society of Edinburgh, and Physician to
the Bath Penitentiary.

[Continued from page 839.]

*The Cure of Apoplexia Hydrocephulica,
or Acute Hydrocephalus.*

You lessen the flow of blood to the head by bleeding. Some bleed largely; I bleed according to the age and strength of the patients,—*e. g.* to sixteen ounces, and repeat it according to the effect. Local bleeding is good;

the best thing is to open the temporal artery. Opening the jugular vein is not to be generally used; it is just as well to bleed in the vein of the arm as of the neck. Bleeding, general or local, is most to be relied on; yet it is little to be relied on.

Blistering the head or neck is useful; from sympathy between the external and internal parts, a blister on the head may relieve the inflammation within; it is a good subsidiary remedy. If there is much of a febrile state, bleed first, then blister. Some years ago physicians would not blister in inflammatory cases.

An issue or seton is a good preventive remedy; not of much avail as a curative measure.

Purging is good. The medicine must be strong, because the bowels are torpid. Moderate doses are to be repeated until the effect is obtained, as ten grains of jalap with three of calomel, every three hours; or senna with rhubarb and salts. Children bear purging better than adults. A young child took, in nine days, 351 grains of calomel,—on some days 60 grains a day; and 198 grains of jalap in six days. The effect was very gentle; there was no purging by calomel at the time. The symptoms were headache, vomiting, and stupor. She recovered, although the torpor of the bowels might seem to indicate a fatal event. You had better try more moderate doses of purgatives.

Some like the sweating plan,—the vapour bath, and fomentations by flannels wrung out of warm water. Some give ten grains of Dover's powder; it is not generally successful.

Some recommend exciting a flow of urine by means of digitalis; it is a powerful sedative of the vascular system; it makes the pulse very slow; sometimes it is used for weeks without our seeing any effects from it. Diuretics are very precarious in their action.

Hydrargyrum is much used, and much slandered; we are disappointed in it in this disease. It is a powerful depleting remedy, and is used also as an aperient, and to enter the system, salivation being thought to be of service, by altering the determination of blood to the brain; which is a mode of reasoning I cannot approve of. It promotes absorption vastly in dropsy;

there is no remedy equal to it for this purpose. We sometimes are unable to cause absorption of the water without it. In a case of ascites I began with it, rubbing it on the belly; salivation came on with violence, so that I was obliged to keep the patient alive with nourishment. The swelling of the belly went off, and he remained well for some time. The mercury alone carried off the water. In another case of dropsy of the belly, from taking cold water, I gave Hydrargyrum cum Scilla; it occasioned a great flow of urine, and removed the swelling. He then left off the squills, and the symptoms returned. He resumed it without mercury; no absorption was produced. He then took mercury, and the dropsy was again carried off. He continued the squills, and was well for many years. I do not remember a case of a flow of urine from diuretics in dropsy without relief of the disease. Sometimes I have seen so great a flow of urine, that I have feared the patient would suffer from the relaxation; yet the discharge has been kept up to sixteen pounds a day, without their suffering from it. Hydrargyrum is not so powerful in the effusion of serum into the ventricles of the brain as in dropsical affections; yet it might be useful in the advanced stages of hydrocephalus. It is very precarious in its operation on the salivary glands. Young children are not easily salivated; one was salivated without the least benefit, who had the disease after tinea capitis. You may give three grains of calomel every six hours, or rub the stronger ointment on the legs, arms, breast.

Errhines are given because there is a want of secretion of mucus in the nostrils; the nose is dry. They are useless.

In chronic hydrocephalus the head has been punctured. In one case the water was evacuated, but it gathered again.

On the Treatment of Epilepsy.

In the prognosis of epilepsy, you attend to the original stamina of the constitution, and to the habits of the patient; for people who lead sedentary lives, and who are intemperate, are more liable to the disease, and to its recurrence.

I only know a dozen cases that ever permanently yielded to the treatment

I employed: all the means recommended are often useless. It is apt to occasion destruction of the mental powers, and to pass into mania. We can no more alter the original constitution than we can alter the complexion, the stature, or the sex. Never promise much; the patients try various remedies and physicians, to no purpose. In some cases there is a confirmed headache, giddiness, and dimness of sight, leading you to suspect organic disease; in others there is no organic affection, but the return of the disease is influenced by habit. A motion once produced in the animal economy tends to recur, as is seen in intermittent fever, in which the hour of the fit supervening can be foretold; so also the flow of blood to the head is regulated by habit. Topical plethora will take place in the head from habit, when general plethora has been removed. The disease is certainly brought on by a sudden rush of blood to the head, when there is no general plethora; this is an imperfect theory, but it admits of very successful application to practice.

There are intervals of years in the recurrence of the fits, yet the disease is not eradicated; it has occurred after a long interval. It is thought likely to cease at puberty when it has begun early; but in many cases no change occurs then.

I do not set down every case that is cured to the remedy employed. In some cases, however, on removing plethora, the disease has been abated or altogether removed; and on the patient's returning to former intemperate habits, or becoming plethoric, the disease has returned. A case of a gentleman who had fever in the West Indies, and after that the piles. The piles were stopped, and epilepsy was induced. I tried for him a cool spare diet, and open bowels, and the fits ceased for months. He then departed from his strict regimen, and the fits returned with severity, and he got into a state of idiotism.

You enjoin a cool spare diet; no other fermented liquor than small beer is to be allowed; distilled spirits and all fat meats are to be strictly forbidden; animal food is to be used sparingly. The patient should live on milk and vegetables, and you must limit the quantity to be taken. Remember the case of the miller, who

lived on curdled milk and flour (mentioned under apoplexy.)

In early cases I bleed; and in other cases, if the fit has been preceded by general or local fulness of blood, as is shewn by redness of the face, vertigo, and a ringing in the ears, I bleed from the arm; yet some say it relaxes the body and increases plethora.

In chronic cases I trust to purging, with sulphate of magnesia, and aloes with colocynth, which is my favourite.

The use of blisters in succession will prevent the turgescence of the brain. A seton or an issue is thought better by many practitioners.

Passions of the mind are to be avoided; and the exciting causes peculiar to the particular case.

Exposure to heat must also be avoided, as sitting near a fire, and in crowded rooms; and sleeping under a heap of bed-clothes: this sort of heat is a bad stimulus to the body. The patient must not sleep on a soft bed, but on a mattress, with a hair pillow: I order this as regularly as a purge in head cases. The fits recur in sleep, from the heat, and the posture, and something more: people going to bed in health are seized with a fit; and in them the subsequent attacks are common in sleep. A lady, subject to the disease in her sleep, got up before the time of its coming on, and walked in the garden, and escaped the fit; this means is worth a trial. In another case of convulsions in sleep, a large opiate at bed-time was successful.

The threatening of the fit has also been stopped by assafoetida and sulphuric ether, and by slight causes acting on the nervous system, as sneezing, and by making a patient start, and by rousing his attention; so also hysteria has been prevented by merely talking of the cold bath.

In some cases, where the fit has been preceded by a deprivation of touch, named *aura epileptica*, which is thought to arise from a local disease of the nerves, whence the irritation is propagated to the brain, the nerve has been divided, and the aura has ceased for a time; but it came back. Do not destroy the part from which the aura proceeds, for it does not always follow the course of the nerve, and it arises from a morbid state of the brain itself.

For the convulsions in small pox, a cool diet and opium is best; for the

irritation of teething, you scarify the gums; for the disorder in the alimentary canal in children, give alkalies, absorbents, and a purge of calomel; for epilepsy from worms, the carbonate of iron has done good. I rely more on purges than on anthelmintics. *Pulvis stanni* is given for the destruction of worms; and if there is arsenic in it, as there is sometimes, it would be fatal to the patient. I have given an ounce of tin filings thrice a day, without a sensible operation, but a feeling of weight in the stomach was induced; and at other times I have seen yards of the tænia come away, loaded with the tin powder.

2. Epilepsy does also take place where there is inanition. You would not try evacuations and low diet then, but give cool nutritious diet, animal food, and a little wine. A patient subject to asthma, was cured by abstemious diet; he then got epilepsy, and the pulse was scarcely perceptible before the fit came on. It was a case of inanition from the means used for the cure of the asthma. I gave him a solid diet, with slight stimulants and claret; and he took an emetic, and *Infusum Armoracæ* and *Pilulam Aloes cum Myrrha*, twice a week. The fits became less frequent, and more moderate; he did not always lose his senses, nor fall down; they then ceased entirely. Here you see the effect of different treatment in different kinds of convulsion.

We have no specific tonics for epilepsy; but—1. Exercise will increase the strength, promote the appetite and digestion, and a proper deposition of nutritious matter; it must be within the limit of fatiguing. The action of the muscles of the arms is promoted by dumb-bells. 2. Cool fresh air, the shower bath, and the cold bath strengthen; I should plunge in head foremost, and come out immediately. Washing the head with cold water thrice a day is good; I never knew it do harm. 3. A long sea-voyage has cured the habit that occasioned the disease. 4. Superstitious remedies, influencing the mind with awe and reverence, have cured it; as eating the sacred birds among the Romans; and the *viscus quercinus*, mistletoe,—the oak being an object of great veneration in the time of the Druids. 5. Bitters are employed; they do possess efficacy,

as is seen in intermittent fevers; but cinchona is scarcely ever successful in epilepsy.

Iron in any quantity or form is not successful; it is thought a tonic. I have used half a drachm of the precipitated carbonate with valerian, without bad effects; when given freely it has carried off worms, and so has done good. Tonics are not to be trusted to.

Arsenic has been given; it was thought a tonic by Cullen; it is not so. It stops ague; how it operates I know not. Is it by strengthening the body? that can be done better by a full diet and exercise. *Argentum nitratum* is thought a tonic, and a cure for this disease; how it is thought so I know not. I have tried a quarter of a grain in a pill without success; it must be taken with caution. One patient came to take a grain and a half daily; then a violent diarrhœa came on, the effect of the acrid stuff that was swallowed; the fits were suspended for six months; yet there was organic disease in this case, which led to a subsequent loss of the mental faculties. The *cuprum ammoniatum* is praised; a large dose has induced violent vomiting and purging. *Oxydum zinci* produces no effect; *sulphas zinci* is a better astringent: I know not that it is good in this disease. *Hydrargyrum*, particularly calomel, purges, and does some good. In the cure of this disease no one remedy, nor all of them together, can be relied on.

The fœtids are thought to be antispasmodic, as valerian, assafœtida, musk, castor, camphor. I knew a dose of musk, fifteen grains, stop a fit of asthma; the patient was tranquil in two minutes. It is safe; you may try it. One patient took valerian, and the fits ceased; it was omitted, and they returned; it was given again with the same success. Dr. Fothergill thought these medicines acted, in epilepsy, by disordering the stomach and impairing the appetite. He was a man of genius and observation. I give some credit to his theory.

Opium may do good in some cases of this disease; it is tried with success in asthma, which is a violent spasmodic disorder, and in hysteria.

On Tetanus.

The robust are most liable to the disease. Warm climates dispose to it;

it is more common in the south of Europe than in Scotland.

1. It is induced by exposure to cold. A person in health going to bed with the window open, is liable to be seized with tonic spasms; so if the wind changes to the north-west, when it becomes very cold. One got drunk, lay down in his garden, was exposed to cold and wet; a stiffness in his jaw came on, which was thought to be rheumatism. It proved to be tonic spasm, and was fatal in three days. It is thought to be endemic among the mountains in children, and is named *trismus nascentium*. I have no faith in its being endemic. Some thought it was from retention of the meconium; others that it was from lesion of a nerve in cutting the navel-string; for when care was taken to purge off the meconium, and when the string was cut more carefully, and the part dressed with oleum terebinthinæ, the disease was prevented.

2. Tonic spasms are induced also by irritation in the stomach and bowels in adults, as is seen in cholera. A patient also, in the course of recovery from an intermittent in the West Indies, got tonic spasm bending the body forwards, from eating too much, and a pine apple, at dinner.

3. Tetanus sometimes occurs after great operations, and also after a slight scratch. In one case, where the face was burnt with a squib, in a few days the patient got tonic spasm, which began in the side of the face that was burnt. If a wound of this sort does not inflame and suppurate, it is thought a sign of tonic spasm coming on; sometimes, however, it has not begun until the wound was healed. In the West Indies, negroes are more liable to the disease from this cause than whites. A negro cut his thumb with a broken china-dish; in a quarter of an hour the jaw became stiff, and in half an hour he was dead. After Admiral Rodney's battle in 1782, of 810 wounded, 88 died in three months; 17 of these died in tetanus.

It is a most dangerous disease; and that from a wound is most so. The diaphragm is affected in it. A person had it from a slight burn in his face; for two days he was better by the cold affusion, and large doses of opium; but it recurred, and was fatal. If a cure is obtained, it is never sudden; the re-

medies must be continued, and urged strongly. Cullen says, if it arise from lesion of a nerve, you are to cut off the communication of the part with the sensorium. The division of the nerve has been tried without success. In a case from a blow on the nose, I cut down to the bone without success. The amputation of the wounded limb has been successful. Caustic applied to the wound, so as to bring on inflammation, has been also successful. In one case I tried it, and could not make inflammation. Oleum terebinthinæ has been poured into the wound, severe pain was excited, and the symptoms abated. It is worth a trial. Some apply opium to the wound to prevent the disease.

The cold affusion has been successful in the tetanus from a wound. I have seen the symptoms alleviated for a time by it, where I poured cold water on the wounded thumb.

In the other varieties of the disease, some give calomel to ptyalism. Opium is the most successful remedy; give it in large doses, but not so as to endanger life. You must give larger doses than in any other disease; give it until drowsiness, or relief of spasm, is produced. One patient took fifteen hundred grains in seventeen days. Ten times the usual dose has been often given, with no stupor, no delirium, consequent. Give five grains of the extract, or, what is better, a drachm of the tincture, every hour, or every two or three hours. Opium in clysters is not so useful as when taken into the stomach. You must use your remedies by the mouth quickly, as the power of swallowing is lost in a few days. Some apply opium to the muscles first affected with spasm; it might be of use. I would not trust to it. You may moisten the plaster with the tincture, and apply it.

The bowels partake of the tonic spasm, and opium increases the costiveness. You must relieve it by the milder purges, as by castor oil, aloes, and senna.

I have little faith in fœtid antispasmodics; but as they are strongly recommended, it is a moral duty to give them a trial. Musk is safe; castor and camphor are little to be relied on; and petroleum likewise. Cinchona is recommended; three ounces have been taken in a day, in a quart of Madeira

wine. Warm bathing, fomentations, and unctuous applications, have been tried. The cold affusion has had a good effect. See Dr. Wright's cases in the London Medical Observations. Strip the patient; pour cold water over him; wipe him dry; lay him in bed; then give a large opiate. The spasms subside, and recur in a few hours; then repeat the cold water. It is a most powerful remedy. Hippocrates mentions it; but it is not noticed by Celsus or Aretæus.

On Chorea.

1. It is connected with the state of the gums sometimes, at the second dentition; you should examine the state of the mouth. In one case the young teeth were cut down upon, and the chorea ceased. In another case the teeth were drawn, and he got well; it returned, however, without any affection of the mouth. I then tried the cold bath and tonics, and he got perfectly well. It sometimes ceases spontaneously at the second dentition. It commonly ceases at the age of puberty. We see little of it in adults; yet it will sometimes continue for the whole of life.

2. It arises also from the state of the bowels. See Dr. Hamilton on purgatives. It is not the particular medicine taken, but the evacuation that does the good. We are not always successful by this plan. Some get well by the use of the cold bath; in others it has not succeeded. It is safe practice with a tonic regimen, as good diet and exercise.

In convulsions with dry gangrene, from bad diet, and old age, evacuations with opiates are the remedies.

On Hysteria.

The sensation of a ball rolling to the throat is thought decisive of a case being hysterical; yet hysteria occurs without it. The convulsions are sometimes like those of epilepsy, and you are obliged to tie the patients down to the bed, or to put on the strait waistcoat. There is great weakness of the mind, with laughing and crying. There is generally some moral cause leading to it; a little emotion of the mind will bring on immoderate laughter or weeping alternately; in one case a most violent tremor came on. It is contagious: a lady, on falling down

stairs, fell into a fit of laughter and crying; the maid servant also fell into laughing, crying, convulsions, and profound sopor. Dr. Cullen thought it might occur in men; but genuine hysteria belongs entirely to the female. It is thought to be from sympathy with the uterus; it rarely occurs before puberty, and it is seen after the cessation of the menstrua. I have seen hysterical symptoms after the age of 60, but it is rare.

An asthmatic paroxysm may occur as a symptom in hysteria.

Various diseases are connected with it, as—1. Amenorrhœa, emansionis et suppressionis. I have often seen it a few days after a stoppage of the menses. The first symptoms were febrile, pains of the head and back, with hardness of the pulse, marking an irregular distribution of the blood; and then followed hysterical symptoms.

2. It is also connected with menorrhagia and loss of blood, where there has been no plethora. You may observe great irritation in the nervous system from bleeding. Epilepsy has been brought on by a sudden depletion of the vascular system; the great debility from this cause may occasion hysteria.

3. Disorder of the stomach and bowels, which is attended with headache, named "clavis hystericus." The chief seat of the disease is the alimentary canal; it is commonly connected with obstruction in the bowels, and with dyspepsia. The globus hystericus seems to be from spasms in the canal; the patient obtains relief from a discharge of flatus from the stomach.

4. Some suppose a connection between hysteria and lasciviousness; this cannot be common, for the disease is brought on by anger, terror, pain, grief, which must preclude lasciviousness. Never give a hint of such a kind in your practice. If the patient is unmarried, you may say, "There is no danger, no objection to her changing her state."

Hysteria is our opprobrium, like other nervous affections. It is difficult to cure, and is apt to recur; it is not to be cured by medicines alone. It is aggravated by improper regimen, and by inactivity of the mind. The patients are apt to give way to it; they might arrest the tendency to it by an effort of the will. You urge them not to give

way to it, by awe or terror, as by a rod well applied, or by threatening them with disagreeable remedies. The terror of the shower-bath has kept off the fits. Thus we break the habit of the disease. Cullen directed bleeding too freely. If you meet with a young hysterical patient, I would have you try bleeding, but not often, nor indiscriminately; if they live fully, and take little exercise, you should regulate the diet; enforce low living, and exercise in the open air; regulate also the costive state of the bowels by calomel and jalap, and clysters of decoction of senna. I would rather trust to Dr. Hamilton's purgative plan than to other medicines. Some physicians give wine, and resort to a free use of opium; the patients get worse and worse from such treatment. In one case, in which the practitioner said, "Ply her well with port and laudanum," the patient was brought to imbecility, and almost to mental derangement. Ether, which is a strong brandy, may counteract the tendency to spasms; yet the transient relief is too dearly purchased. Fœtids, as assa-fœtida and valerian, are used from their sensible qualities, and a curious notion respecting the uterus. Burnt feathers used to be held to the nostrils; it often affected the nervous system. Tonics have been given, to lessen the irritability of the constitution. All tonic drugs are ineffectual. I trust to well-managed diet and exercise, cold bathing and the shower-bath, and being much in the open air; this strengthens, and lessens irritability. One patient, who was thought unable to sit on horse-back, was put on a horse while in hysterics. I said, "You may fall off if you please; but you shall ride;" and she was much benefited.

Occupying the mind is good; more women get hysteria by keeping in a hospital than are cured there.

In a case of hysterical spasm in the throat, I tried electricity with advantage.

[To be continued.]

RECORD OF CASES.

By THOMAS MAYO, M.D. F.R.S.

Physician to the Infirmary of St. Marylebone.

(For the *London Medical Gazette*.)

[Continued from p. 487.]

At the commencement of this record of cases I have pointed out an expediency

which attaches to such records, apart from any value that they may claim from novelty of communications;—namely, as supplying, or rather contributing to, the great stock of materials from which every day's practice is drawn. Nosological descriptions supply, indeed, the points essential to the type of each disease, and would be illogical if they travelled into non-essential matter. They are, in fact, diagrams, and, as such, perform a function on the importance of which I need not expatiate: no one can safely advance into practice, or even use his own experience, without risk, unless thus instructed. But, after all, it is from individualised cases of his own, or others, that he immediately obtains those analogies from which he must act at the bed-side; and that man *cateris paribus* is the best practitioner, who, having been enlightened by a just nosology, can bring to bear the largest number of remembered facts. Hence the value of a record of cases; about the novelty of which, by the way, we need not be anxious, if we give them honestly, for no two cases ever were alike.

Lady H., aged 54, of a full and flaccid person, long subject to hysterical affections, was attacked by rigors, soreness of throat, and extreme general uneasiness, on the 7th of February, 1841. She had been attended by a judicious general practitioner to the 10th, on the evening of which day I saw her with him at nine.

The pulse and temperature of the skin were low; the tongue dry and brown; the tonsils of a purplish hue, slightly enlarged, with some coagulable lymph on their surfaces; the face pallid and sunken. I observed a slight redness on the arms and chest—so slight that it seems never before to have attracted attention; still its character appeared to both of us decisive on careful examination. I learnt that the bowels had been acted upon by several aperient doses, and that eight grains of calomel had been given. If we had not possessed evidence of the presence of scarlatina, we should still at that period have considered the patient in great danger. Her consciousness, I should observe, was then unimpaired; but I understood that during each night she had been occasionally delirious. Sinapisms were directed by us, the decoction of cinchona, with the sesquicar-

bonate of ammonia, and other cordials, freely given during the night, and at an early period of the morning we had the advantage of Dr. Latham's advice in favour of this system. But the patient sunk rapidly, and the case terminated by half-past 12 P.M.; not the slightest reaction having taken place.

No autopsy was permitted.

On the 21st of March, more than five weeks after this event, in the same house, a son of Lady H., a fine, well-grown florid boy, aged 7, having been up to that day in his ordinary state of good health, was attacked, towards the evening, with rigors, vomiting, and feverishness. He was seen by a general practitioner the next day, who gave him, at 3 o'clock, P.M.—

Hydrarg. Chlorid. grs. ij. ; Pulv. Jacobi, grs. iij. ; and at 5 P.M. a solution of Magnesæ Sulphas in Infus. Sennæ Co.

About this time I saw him. His pulse was 110; his tongue dirty; his face flushed; his head aching, and his forehead heavy. The bowels, I learnt, had not been relieved the previous day; a clayey motion occurred while I was in the house. The character of his then symptoms was that of common bilious obstruction, with constipation and pyrexia, except that there was fulness and redness of tonsils, with coagulable lymph on portions of them.

At 8 o'clock, P.M. I saw the patient again with the general practitioner. The flush of the face had then subsided; the head, according to the little patient, was comfortable; some appearance of ulceration of the tonsils, and a few small spots on the chest, but nothing either there or on the face amounting to incipient scarlatina. The bowels had acted three times, and in the latter motion there was good bile. The pulse was quick, less full; heat of skin correct. The mind was disposed to wander.

Emplast. Lyttæ applicetur Nuchæ.

R. Mist. Camph. ʒi. ; Potassæ Bicarb. grs. x. ; Ammoniacæ Sesquicarb. grs. v. ; ex Suc. Limon. coch. parv. iij. 4tis. horis.

22d, 10 A.M.—Very incoherent during the past night. Motions had passed unnoticed by him, though awake at the time; and though the blister has risen, he lies upon it without any complaint of it. No eruption; throat more ulcerated; urine plentiful.

Perstet. Let strong beef-tea be given freely.

Half-past 5, P.M.—Urine and motions pass unnoticed, but in moderate quantities. His mind wanders continually; some pale distinct spots on the chest. The tongue, which had been dry and brownish in the morning, is moister; tenacious mucus hangs about the fauces. The pulse is soft and regular, not weak; 130 in number. Carotid action, which had been considerable in the morning, is diminished. He now refuses medicine, and rejects the broth from his stomach mixed with green bile.

At about 7 o'clock P.M. he became cold and pallid, and his inspirations frequent and hurried. By 11 o'clock on the same night he was dead.

Applying my ear to his chest, about half an hour before this event, I found the respiration perfectly vesicular, and the action of the heart normal, though very frequent.

Post-mortem.—Sinuses of the brain very turgid with blood; effusion of serum between pia mater and tunica arachnoidea; pia mater gorged with blood in every part; numerous bloody points observed in cutting through the substance of the brain, which was of normal consistency; left ventricle very full of fluid: but little in the right, which probably arose from the depending position of the left side while under examination.

Viscera of abdomen and thorax normal, except an effusion of about half an ounce in the pericardium, and some concentric hypertrophy of the left ventricle.

These two formidable cases were fatal with all the rapidity of an intense morbid poison. In that of Lady H. the fatal tendency of the disorder was manifest for at least sixteen hours before death. But it is a remarkable fact, that a practitioner, whose name would be a sufficient guarantee of his experience and talent, saw the little boy not more than three hours before his death, (being accidentally called in through the anxiety of the parent), and gave then a decidedly favourable prognosis of that case.

After the death of Lady H., ample means were taken, by cleaning, and chloride of lime, and removal of linen, to purify the house, itself airy, and situated near Hyde Park. The child staid in the house with the rest of the

family, and sickened on the 38th day from his mother's death.

The progress of these two cases is unsatisfactory in respect to treatment. One point certainly deserves notice, that very active measures were in each case taken to relieve the disorder by operating on the *primæ viæ*. Did these measures lessen or improve the chance of the exanthema coming forward?

This activity of purgation was carried out more strongly in the case of the mother than of the son, and her prostration of strength was extreme. Yet the duration of the latter case was even shorter than that of the first.

[To be continued.]

ACCIDENT

TO THE

SHOULDER-JOINT,

ATTENDED WITH SOME PECULIARITY OF SYMPTOMS OF RARE OCCURRENCE.

To the Editor of the Medical Gazette.

SIR,

THE following cases*, which I have lately seen, are at your service, if you think them likely to interest your readers.—I am, sir,

Your obedient servant,
J. COLLIER, M.R.C.S.

Brackley, April 2, 1845.

Miss A., Jan. 26th, 1845, whilst crossing her bed-room in a hurry, endeavouring to save herself from falling, instantly put out the left arm at full length to hold by the bed-post.

The sudden and unexpected extension of the whole limb immediately caused the head of the humerus to slip from its proper place, leaving a slight depression below the acromion, giving the shoulder a sunken appearance. She could, by moving the arm about, herself replace it in the glenoid cavity, and as easily displace it; the act *not being attended with pain*.

This singular case was also seen by Dr. Robertson, of Northampton, a few hours after, who at that time was attending another part of the family: he expressed his astonishment at the patient's agility in oscillating the joint, never having seen or heard of a similar case. A figure-of-8 bandage was used,

the arm confined to the side, and properly supported in a sling for six weeks. The patient can now move it very well without displacing it.

There can be little doubt here that the dislocation arose from muscular action.

I have taken the liberty of transcribing the following case from the Provincial Medical Journal, as bearing some resemblance to the above.

“Richard M., æt. 31, a gamekeeper. A few days ago, whilst hunting and destroying rabbits, he pursued an unfortunate one to his burrow, which latter took a nearly horizontal course into a thick fence. Having a long arm, he conceived the possibility of reaching the animal at the extremity of its recess, and being just able to touch it with his fingers, he made a strong effort to force the arm deeper, and, as a consequence of this violent straining, the head slipped out into the axilla, and he was obliged to relinquish his grasp.”

HÆMORRHOID NEEDLE.

To the Editor of the Medical Gazette.

SIR,

I BEG leave to forward to you a drawing of an instrument which I have recently invented for the purpose of applying ligatures to small tumors of the vagina and of the rectum.

This instrument will be found particularly adapted for the removal of hæmorrhoids. It not unfrequently happens in these affections that considerable difficulty is experienced in getting the ligature to remain close around the base of the tumor, and sundry attempts are made ere the operator succeeds. This is peculiarly the case when the tumors are not very prominent, their bases broad, and a number of them are situated close to each other.

The ordinary mode of proceeding in such cases is to pass the ligature around the tumor, with the right and left index fingers, either aided by a tenaculum or not, as the operator may deem expedient: with the utmost precaution it sometimes occurs that our endeavours to complete the operation are embarrassed by the constant slipping of the ligature; or, what is still

* We omit the case of dislocation of the hip-joint, as we do not find in the report anything out of the ordinary way.—ED. GAZ.

View of underside of Instrument, shewing the groove for entrance and outlet of silk cord.
A, entrance for silk. B, Continuation of groove. C, Exit groove upon point of Instrument.

worse, the operation may prove unsuccessful, from the ligature embracing a portion only of the hæmorrhoid.

Such accidents are less likely to occur when the hæmorrhoid needle is resorted to, for it enables the operator with great facility to keep the silk in close contact with the base of the tumor, and when two or three are close together, and are situated high up the rectum, the ligature is readily passed between them.

As seen by the drawing, the instrument is of very simple construction, and in shape is somewhat similar to a button-hook: on its under surface is a groove for the reception of the silk, which latter must be well waxed before it is used; at each extremity is a slit or notch for the purpose of nipping the silk and retaining it in its proper situation.

The operator carries the needle, previously threaded, behind the tumor, and, with the handle slightly raised, in

order that the groove may be brought to bear upon its base, he gives it to an assistant to hold, directing him to keep a steady and firm pressure downwards and outwards: the operation is then completed in the ordinary way; the ligature as it is tied releasing itself from the groove of the needle.

A modification of the same instrument might, I think, be advantageously resorted to for the removal of polypi and other tumors of the uterus.*

Your obedient servant,

G. BARLASE CHILDS,
Surgeon to the City Police Force.

CASE OF LABOUR, COMPLICATED WITH RECTO-VAGINAL HERNIA.

By PROFESSOR MEIGS.

MRS. R., aged about 30 years, the mother of four children, all of which were born by easy natural labours, and

* The needle is made by Mr. Fergusson, of West Smithfield.

one of them in a labour of only two hours, was seized with the parturient pains at half-past eleven o'clock last night. She was at full term, and in good health, save that she had complained much of an unusual pain in the right side of the abdomen, and particularly in the right iliac region.

Her physician, Dr. Bicknell, was called to the charge of the case:—Dr. B. discovered a tumor occupying the cavity of the pelvis, which impeded the progress of the labour. The woman's pains were frequent and violent, and attended with the most excessive tenesmic effort at bearing down. Dr. B. invited me to see the patient, and I arrived at two o'clock, P.M., at her house in West Philadelphia.

The external parts were in a relaxed state. The index finger used in touching was pressed towards the symphysis pubis, by the tumor, which seemed nearly to fill up the pelvic cavity, and effectually to debar the head even from engaging in the superior strait, though the labour had continued already 14½ hours, in the case of a woman who in all other labours was occupied but two hours with the whole process.

I could just conveniently touch the presenting part of the head, which was in the 4th position of the vertex presentation. The os uteri fully dilated.

The tumor was compressible. I touched by the rectum, and so discovered that the tumour was in the peritoneal cul de sac betwixt the rectum and vagina, but distending that cul de sac enormously. The diagnosis could be nothing else, considering the softness of the swelling, than a vaginal enterocele, which I immediately proceeded to reduce.

The woman was placed on her left side. The knees drawn up. I introduced the fingers of the right hand into the passage, and pressed the ends of them against the lower part of the tumor. By keeping up the pressure a short time, during which I repeatedly exhorted the woman to be passive, and not to bear down at all, I could cause the whole mass of the swelling to rise up towards the back part of the superior strait. As the mass ascended, it grew smaller, until, on a sudden, the whole tumor slipped beyond the reach of the hand, and was lost. I announced

this good fortune to the patient, and exhorted her not to bear down at all with the approaching pain lest the gut should again prolapse. The pain that ensued brought the head nearly through the superior strait, and partially rotated the vertex. The second pain rotated the head and propelled it on the perineum; the third brought the vertex considerably beyond the pubic arch, and the fourth expelled a very large and healthy child; after which the placenta came off in a few minutes.

I look upon this as a very interesting case; not merely on account of the rareness of vaginal enterocele in the pregnant female, but as exhibiting the power of such a tumor to suspend and impede the progress of a labour in all other regards natural and healthy.

I presume, as so many hours had already elapsed in vain and exhausting efforts by a strong woman, that there was reason to fear a dangerous strangulation or contusion of the displaced bowel; and that it was fortunate for the patient that the intestine could be returned above the plane of the strait. The rapidity with which the head passed through the whole pelvis and the soft parts, as soon as the obstruction was removed, showed conclusively that the vaginal enterocele was the cause of her distress. As I have never met with such a case before, I thought that the publication of it might prove useful to some of the younger of your readers, should one of them happen to meet hereafter with a similar instance of difficulty.*

ANALYSES AND NOTICES OF BOOKS.

"L'auteur se tue à allonger ce que le lecteur se tue à abrégé."—D'ALEMBERT.

Observations on the Growth and Irregularities of Children's Teeth. By W. H. MORTIMER, Surgeon Dentist. London, 1845. 8vo. pp. 130. 2d edition.

THE object of the author in publishing this little volume, is, according to his own statement, to lay down fixed rules respecting the management of the teeth, "by which parents may judge for themselves in the absence of a competent person;" and it is also his design

* Philadelphia Medical Examiner.

that it should serve "as a guide or reference, when any doubt exists as to the capabilities of those within reach." It will therefore be inferred that the work has more of a popular than of a professional character. His intention, however, has not been to make "every person his own dentist;" but to cause parents to attend more than they are commonly in the habit of doing, to the effects of dentition on the health of the child, and to ensure by very simple precautions, the growth of a sound and regular set of teeth.

In respect to lancing the gums, the author recommends that this operation should be performed only when the tooth is so near the surface, that it is impossible for the cicatrix to reclose over it. p. 25. He seems to consider that the production of a cicatrix offers much greater obstacle to the protrusion of the teeth than the hard gum itself. He therefore considers the operation worse than useless when performed early. With regard to his reason for its non-performance, namely, the production of "a cicatrix," we remember being taught that a cicatrix was a newly formed part, and being therefore endowed with less vitality than the contiguous structures, it was more easily removed by absorption. Some dentists appear to regard these cicatrices of the gums in the same light as hard and knotted cicatrices of the skin, of twenty or thirty years' standing. The author differs in opinion from Dr. Combe respecting the time at which animal food should be given to an infant. Dr. Combe appears inclined to postpone a full animal diet until the permanent teeth have appeared. The author thinks, and most persons will agree with him, that the appearance of the first set of teeth indicates that the use of the animal food may be properly commenced.

The milk-teeth are very apt to decay, which the author ascribes to want of cleanliness, and which is no doubt a very common cause of decay in children and adults. These teeth should on no account be removed,—their removal should at any rate be delayed as long as possible; "for if extracted before the other teeth are ready to supply their places, the contour of the jaw becomes smaller, and there is not then sufficient room for all the second teeth." p. 37. He recommends that the decay, if commenced, should be arrested by

artificial means: and he is evidently looking forward to the appearance of "a Newton," in Dental Surgery (!) to explain the anomalies observed with respect to the dropping out and decay of the teeth.

Gold cannot be often used as a stopping in the milk-teeth, since they will not bear the pressure required. The author's plan is to use an amalgam composed of powdered silver five parts, and mercury one part; the surplus mercury being mechanically separated. This, according to him, is what is commonly advertised as the "mineral succedaneum." Another stopping which he recommends is a compound of five parts of bismuth, melted with three parts of tin, to which one-twentieth part of mercury is to be afterwards added. The cavity of the tooth being thoroughly dried, some pellets of this compound are dropped into it, and they may be melted into a solid mass by a blunt-pointed steel instrument heated to about 160°. p. 38. The sole object of this operation is to keep the tooth in until the jaw has had sufficient time to expand; for the early removal of one of the first set induces the speedy appearance of one of the permanent teeth, and irregularity is the consequence.

As the stopping of the tooth is intended to be only temporary, we do not see why Dr. Rolff's ingenious suggestion should not be adopted:—*i. e.* a small pellet of caoutchouc is to be softened by heating it on the end of a wire, and it may then be introduced into the previously cleaned and dried cavity of the tooth. This is said to have proved an excellent remedy for tooth-ache even in adults, and it has the advantage of being easily applied without the aid of a dentist.

The milk-teeth should not be removed until quite loose, and then in pairs, in order to preserve regularity of growth in those which follow them: but they must be at once removed, whether loose or not, when any of the second set appear, either on the inside or outside of them. Again, it is properly recommended that the adjoining teeth should not be taken out until those already removed are replaced p. 46. Inattention to this point produces great irregularity.

The following remarks are of practical importance, and may be new to some of our readers:—

"At about six, the first teeth of the second set begin to appear; they are large double-teeth, and are situated behind the last milk-teeth at each extremity of the upper and lower jaw. When these teeth are perfectly formed, they serve, being placed one over the other, as a support to the gum while all the first set are changed. * * * These teeth, from the early age at which they appear, and from want of attention to cleanliness, almost always decay in early life, and very often shortly after they have made their appearance. During the progress of dentition, no attention is paid to them, under the supposition that they are milk-teeth, and that consequently they will be changed; if therefore they decay, no notice is taken of them until they give pain, when the child is taken to the dentist to have them extracted." p. 39.

The author advises that they should be stopped so soon as caries appears, and further remarks, that "out of every hundred children that are brought to me, of more than eleven years of age, at least ninety have some of these teeth in a decayed state, and ninety-five out of one hundred adults have lost one or more of them, whereas, had they been properly attended to, they might in all probability have been saved." p. 41. We believe that there is some truth in these observations, and that many persons when young have lost their teeth through the ignorance of those whom their parents consulted. Miss Martineau's case has lately given a fresh impulse to mesmerism, and we shall probably hear further of the application of this piece of charlatantry to the operation for the extraction of teeth. Our author remarks on this subject:—

"To those experiments that have been recorded respecting the removal of teeth during the mesmeric trance, without the knowledge of the patient, and based upon the evidence of their not showing any outward sign of pain, I attach but little weight. There are too many instances on record which prove the amount of physical sufferings that the body can endure without any outward demonstration of pain, to attach much importance to such a proof (an assumption?). Until, therefore, something more clearly demonstrative is brought forward, I must incline to believe that there is not sufficient evidence to establish the fact (the alle-

gation?). And even if there were, I firmly believe that mesmerism could and would only affect the few whose nervous systems were in the morbid condition necessary to receive its influence. On the healthy and vigorous mind, it will fail to produce any of its mystic effects." p. 92.

Before mesmerism was resuscitated, as it has been within the last few years, we remember witnessing the operation for the removal of the breast in a woman, who evinced no other signs of suffering during its continuance than that of a slight tremor. It is strange that some men will now resort to such absurd hypotheses in order to explain these well-known facts.

The author rejects the Ehrenbergian notion of the tartar of the teeth consisting of minute geological deposits of animalcula, but he at the same time admits that they exist in everything!—a conclusion to which present microscopical researches appear to be daily tending.

On tooth-powders the author is vague, contenting himself with laying down rules for what ought not to be used; nevertheless, he thinks them as necessary to the proper cleansing of the teeth as soap is to the cleansing of the hands. Probably tooth-powders are required, owing to the present degenerate state of the human race; for he observes, "in all the jaws that I have ever seen of a very remote period, some more than two thousand years old, the teeth have invariably appeared healthy." p. 107. He is evidently here alluding to the jaws of the Shepherd kings—the Amenophs and Rameses of the olden time—to whom probably tooth-powders (certainly such as are now used) were unknown.

Having thus given an analysis of the contents of this little book, we cannot close our notice without pointing out what we consider to be blemishes. The style is rather too easy, and somewhat approaches that of certain American writers. Thus, at p. 78, in reference to the proposed establishment of a "Children's Dental Club," as we interpret it, the author speaks of admitting his little annual subscribers "at a low figure;" and he recommends such clubs to the public generally for "two great desiderata most sought after—security and economy." This appears to be too much like a shopkeeper's

advertisement, especially when, just before, he speaks of "the result having always proved very satisfactory (to the patient or the dentist?) as very few irregularities [of the teeth?] have occurred in such cases." Again, at p. 120, we find the following passage in reference to artificial teeth: "The best substitute, for durability and cleanliness, is undoubtedly the mineral teeth, made as I alone have been in the practice of making them." There is a sort of apology for this self-laudation in the shape of a note, which, however, does not much mend the matter, as we find by it that the original inventor communicated his process to *only two* persons, *i. e.* the author "and another, who does not make them; and although several attempts have been made to imitate his teeth, I believe they have invariably proved unsuccessful." Note, p. 120. We look upon this as a covert advertisement. We would ask the author whether every dentist does not regard his own plan as the best; and, admitting the superiority of "his mineral teeth," whether he never heard in Paris, in which city he resided for some years, of the French proverb, "*le vrai n'est pas toujours le beau*?" We regret to find these defects; for the work contains, in a small compass information whereby practitioners who do not want to go deeply into the "mysteries of dentistry," may profit. It is also illustrated by some fair drawings, executed in the new art of glyptography.

 publicum sit, dicendi periculum non recuso."

CICERO.

ON THE PROPOSED CHANGES IN THE PROFESSION.

WE continue to receive from all parts of the country so many copies of protests, memorials, petitions, and resolutions, that even if our pages were double their present extent, we should have some difficulty in giving insertion to all of them. We elsewhere print a

memorial from the Hereford Association (p. 941), signed by a number of respectable practitioners, whose diplomas bear date from 1796 to the year 1843. A copy of a petition to the House of Commons, embodying similar resolutions, and signed by many respectable members of the College, old and young, has also reached us from Wolverhampton; if we do not give it insertion, it is that we only find in it, an iteration of grievances which have already met with a full exposition in our pages. From Liverpool we have received a copy of a memorial addressed to Sir James Graham by the medical profession of that town. We shall select from this memorial two extracts, which appear to us to contain new matter. Some objections to the proposed changes in the profession are put in a strong light, and certainly deserve mature consideration. With respect to the fellowship being given of right to the future registered "surgeons," while it is withheld from those now practising as such, we fear it will be said, from the tenor of the recent answer of the College of Surgeons to the memorial of the National Association, that the permission given to present members to register as "surgeons" must be looked upon as a favour, and as a kind of indemnification for the loss of the fellowship. We here extract the two resolutions to which we refer:—

"That your memorialists are of opinion, that the power granted to the Council of Health by clause 28 of the bill, of making regulations for specifying what form of testimonial shall be necessary to qualify the holder for appointments to public institutions, may become liable to abuse; and they therefore consider that a matter so deeply affecting the interests of the profession should be fixed by statute, or left, as at present, to the decision of parties supporting such institutions.

"That by clause 19 of the bill, 'every person registered as a physician or

surgeon under this act, shall be admitted as an associate of the Royal College of Physicians, or as a fellow of the Royal College of Surgeons, from which he shall have received his letters testimonial as physician or surgeon,' while the act makes no provision for the admission of persons at present practising as physicians or surgeons to the same privileges, your memorialists consider this a serious omission in the bill, inasmuch as persons engaged in active practice have not the opportunity of obtaining these privileges, and must necessarily, and without any fault of their own, be placed at a disadvantage by others entering the profession subsequently to the passing of this act. That the holders of surgical diplomas have especial cause of complaint, inasmuch as, on obtaining such diplomas, they were admitted to the highest position in their profession to which they could *then* attain, while the present measure provides for the advancement of all future surgeons at once to the rank of fellows, and by so doing places them in a higher position than their seniors in the profession, and that without any superior merit to entitle them to such advancement."

The Council admit in their answer (see p. 906) that "many who have not been included in the list of fellows are well known to have attained the highest eminence, and to enjoy the highest reputation as practitioners in other departments of the profession," &c. Now the real question between the College and the profession appears to us to be, whether they have not included in their lists of fellows, many persons who do not possess so high an eminence, either as surgeons or practitioners, "in other departments of the profession," as a large number who have been arbitrarily excluded. We have reason to believe that the feeling that an error has been committed in this respect does exist even among some members who have, or ought to have, influence in their counsels, and that there are among them men disposed, with conscientious motives, to do justice to the excluded. The

Council think that it is "a misconception of the nature of the qualification," to infer, as is done by so many members, that omission from the list, implies "professional degradation." We do not think that there can be two opinions on the point. They have omitted members of the College, who are neither "professional paupers," nor "persons of notoriously bad character," neither puffers" nor "vendors of nostrums," nor are they "writers of indecent advertisements," or in alliance with chemists and druggists; and, with regard to surgical attainments, and their ability to promote the science of surgery, they are quite equal, if not superior, to many who are now ranked as fellows. The College contend that there is no degradation in the omission; and yet they virtually admit, that the members must be a class degraded below the fellows, when they assign among the reasons for not adding more members to the list, that there are among them "professional paupers, persons of bad character, vendors of nostrums," &c. &c. Is there no degradation in being mixed up with a class of this description? Would not the fellows themselves feel greatly degraded, if such persons were admitted to the fellowship? And yet we are told that this feeling of degradation among the members is founded in a misconception on their part. Would it be a misconception on the part of the fellows if matters were reversed? We believe not,—and it would be better at once to acknowledge openly, what is implied inferentially, that the fellows are intended to be a select and superior class!

Our honest conviction is, that the College have been led into a serious error in the appointment of the fellows. The principles upon which they went were only apparently good, and they have been attended in many cases with great injustice. There is no doubt that

many who are now among the excluded would have been admitted had their qualifications (undoubtedly superior to those of many fellows) been known. Either from not making any claim for the fellowship, or from making the claim too late, many of the present members have been excluded; and they have, we think, reasonable cause of complaint. The College did not call upon its members to send in a claim with their qualifications, although there was ample time for a principle of this kind to have been adopted, or we believe they would have come to a very different decision with respect to many of the names. They would have found that there were some who had a far better right to have the fellowship conferred on them, than others whom they ultimately selected, and who probably by a fortunate chance found a member of the Council to speak for them. Again, it is not improbable that the qualifications of others among the excluded became a subject of discussion in the absence of those members of the Council to whom alone their qualifications could be known. In these cases injustice has been done by accident, and we verily believe that there are not a few members who can trace their exclusion and their present incorporation with "felons," "venders of nostrums," and "writers of indecent advertisements," to this cause alone.

It is very true that any principle of selection might appear invidious to those who found their names omitted; some kind of injustice would perhaps be done in all cases; but the greatest pains should be taken, in carrying out a principle of this kind, that this injustice should be of the least possible amount. The complaints of many hundreds of respectable members, and the advice and remonstrances of many of the "fellows" themselves, show that the plan adopted has not been just.

The maximum rather than the minimum of injustice has been the result. We have reason to believe that some members made no application for the fellowship, guided by the example of others, who however found themselves in the first list from an application having been directly made to them. Some again fortunately had a friend to speak for them, when their names were taken: in no other way is it possible to account for the arbitrary manner in which members have been admitted and excluded:—and yet the Council assert that "they have done what was required of them to the best of their ability, and have made the selection altogether on public grounds, without favour or prejudice, and uninfluenced by private motives"! (p. 906).

There is still a *locus penitentiæ*. The injustice may be removed without making *all* members fellows—without following that kind of seniority in the selection which necessitates an association with felons and persons of notoriously bad character; or without converting the College of Surgeons into a College of General Practitioners. The way has been pointed out by some among their own body*, and we have the strongest reason to believe that, on a request being made, the Government would not hesitate to grant a supplementary charter, in order that the College might repair a proved injustice. If they doubt whether they have acted unjustly, let them not refer to their own motives, but at once call upon all the members who feel aggrieved to send in a claim, and let their qualifications be fairly decided by the whole of the Council, according to the same standard which they adopted with respect to a large number of the present order of fellows.

That the Government are ready to

* See the letter signed Mediator (p. 939). The writer of this letter is one of the selected, a practitioner of long standing and of great experience.

join the College in carrying out a principle of this kind will be apparent from the following extract, forwarded to us by a correspondent who heard Sir James Graham make the observation in answer to a deputation of members.

"Sir James Graham said, he did not regret that he had devoted much time to the consideration of this subject. He felt that a class so useful, so honourable, and usually so peaceful, as the medical profession, deserved the highest care of the Government. *If the members of the College of Surgeons could prevail upon the Council to extend the num'ber of fellows, he would gladly co-operate in the obtaining of a new charter of incorporation from the Crown.* But he could not undertake to coerce the Council to such a step. The matter now lay entirely between the members and the Council of the College of Surgeons."

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Tuesday, April 8, 1845.

DR. WATSON, VICE-PRESIDENT,
IN THE CHAIR.

On the Colostrum of the Cow: with Remarks on that of the Human Subject.
By JOHN DAVY, M.D. F.R.S. Inspector-General of Army Hospitals, &c. [Communicated by DR. HODGKIN.]

THE colostrum—the new milk of the cow after calving—differs, as is well known, from the ordinary cow's milk, in being of a rich yellow colour, less liquid, of greater specific gravity, and in possessing the property of coagulating when heated. On this account it has been supposed to be more animalized than common milk, and to contain even serum. This inference not having appeared to the author to be satisfactorily proved, and, *à priori*, not very probable, he was induced to subject it to some trials, the results of which he describes.

The details of these experiments are given, and the inferences he draws from them are to show that the peculiarities of the colostrum do not depend on the presence of serum—in short, that the colostrum is destitute of serum; and that its coagulability by heat depends on a peculiar modification of its caseous portion.

That the caseous portion of milk does admit of no inconsiderable modification is shown (the author observes) in a remarkable manner in comparing it as existing in human milk, and in cow's milk; in the latter, even in its ordinary condition, it is so readily coagulable, whilst in the former it resists this change, whether acted on by acids or rennet, and yet is easily obtained by means of evaporation when freely exposed to the air.

Physiologically considered, the most marked circumstances belonging to colostrum are—the concentration of nutritious matter in it, the greater facility of its coagulation by rennet, compared with older milk, and its greater power of resisting change when exposed to the action of atmospheric air. These the author remarks are qualities which may be eminently serviceable, viewing it as the first food of the young animal. Its easy coagulation may adapt it to the stomach, in which organ probably the gastric juice is at first small in quantity and feeble. Its power of resisting change, and remaining semi-fluid, may render it fitted in the intestines to promote the removal of the meconium; whilst its concentration as nutritious matter may fit it to perform for the calf the same part that the substance of the egg serves, which enters the intestine during the latter stage of foetal development, in the instance of birds, reptiles, and fishes.

The author observes, that if his inferences as to the use of the colostrum in the cow are correct, it may be expected that the first milk of other animals, at least of those, the young of which are born fully formed and vigorous, will be found similar; and, so far as he has been able to learn, it is so. Whether the first milk of those animals the young of which are helpless and feeble—as the carnivoræ—is also similar, cannot be determined for want of facts; but he is disposed to conjecture that it is, having found the first milk of the bitch to coagulate when heated, and to yield a large proportion of animal matter (35·2 per cent.)

In the carnivora, it may be requisite for the first milk to be rich, as these animals have to leave their young to procure food, and to be absent, it may be, an uncertain time. In accordance with this, too, the author observes, is the fact that the human milk, the first drawn, is not unusually rich, and does not coagulate when heated; at least, such are the results of the experiments he has made, and which are given in the paper.

The author concludes by remarking that this diluted state of the human colostrum seems equally suitable to the offspring and mother: the one, helpless and feeble, not requiring concentrated nourishment; the other, commonly from a certain degree of exhaustion during labour, ill fitted to yield

such a supply,—offering, in this point of view, another instance to the vast number of examples of harmonious adaptation, and it may be, also, one circumstance more by which man, as an animal, is distinguished from every other.

Dr. Copeland rose at the conclusion of the paper, and expressed his opinion that the chief object of the Society was the reading and discussion of practical papers. He therefore felt aggrieved that a paper so entirely chemical, and some of the physiological points of which were so questionable, had been allowed to be read, particularly as so many papers of a practical nature were in possession of the Society, for the reading of which there was so little time. Something was due to an author in the selection of a paper, but something was also due to the Society, as members were disappointed when papers like that just read, were brought before them.

Case of Obstruction of the Large Intestine, in which the ascending colon was opened with success, the patient dying three months afterwards of another disease.
By SAMUEL EVANS, Esq. of Derby.
[Communicated by WILLIAM BOWMAN, F.R.S. Assistant-Surgeon to King's College Hospital.]

Lewis Street, æt. 23, a farmer, has been liable for several years to attacks of diarrhœa. In September 1843, he was seized with violent pains in the bowels, resembling colic, which lasted thirteen hours. About the third week in January the attack recurred, and became more severe on the 5th of February: the author saw him for the first time on the 7th. He was suffering from severe intermittent pains in the abdomen, which was distended, but free from tenderness. There was a distinct swelling in the right iliac region. His bowels had not been relieved since the 5th. Opiates, active aperients, and stimulating injections, were administered during five days without relieving the pain and sickness, or procuring evacuations. On the 12th and 13th, his sufferings were relieved by large doses of the *Liquor Opii Sedativus*. From this time to the beginning of April the size of the belly gradually increased; he also daily suffered many paroxysms of pain; at intervals, large quantities of flatus, and small portions of clay-coloured fæces, escaped from the bowels. The patient's health became much impaired, and vomiting recurred almost daily. On the 25th of March, Callisen's operation, as modified by Amussat, for the formation of an artificial anus in the loin, was proposed, but the patient yielded to the wishes of his friends in postponing it. This emaciation increased, and the abdomen

became distended to the greatest possible degree; the evacuations entirely ceased, and the pulse became feeble and fluttering.

April 9th.—The operation was performed. A transverse incision, four inches long, was made in the right loin; the ascending colon was opened, and more than two gallons of semifluid clay-coloured fæces were discharged. He recovered from the operation, and by May 9th had gained flesh; the wound in the intestine had healed, but the evacuations escaped entirely by the artificial anus, being restrained by a plug in the orifice, which is removed four or five times a day. At the end of June he commenced passing diabetic urine, and to suffer from thirst.

He rode a distance of six miles in an uneasy cart, and shortly afterwards symptoms of peritonitis supervened, and he died on the 5th. On examination of the body, the cause of obstruction was found to be a stricture in the colon, just beyond the angle formed by the junction of the ascending and transverse portions of the gut. The contracted part was almost as hard as cartilage, and would only just admit a crow-quill; its inner surface was ulcerated. The cœcum was enormously distended, and nearly as large as a stomach of ordinary size; the ascending colon was also much enlarged.

The author remarks that this is the eleventh case on record in which Callisen's operation, modified by Amussat, has been performed in the adult in consequence of obstruction in the intestinal canal. From the previous history of the case, it would appear that the disease had been of slow progress, and of considerable duration; but at the period to which the operation was delayed, owing to the interference of the patient's friends, he was in so alarming a condition that it is impossible to imagine a case more unfavourable for the operation. Two months afterwards he was so much recovered that there appeared to be every prospect of his restoration to health; but these hopes were disappointed by his imprudence in regard to diet and exercise; but as far as the operation is concerned, the case was successful.

Sir George Lefevre remarked on the indiscretion of the patient in going about so soon after the operation, and thought this should have been prevented by the medical attendant. Local and general treatment, together with the recumbent position, and strict attention to diet, were essential to the satisfactory conclusion of such a case. He briefly referred to two cases of which he had drawn up a description and published. In one of these cases a lady of distinction in St. Petersburg had had the colon punctured merely for the purpose of relieving the pain caused by distension. In this case the suf-

fering was extreme ; there was incessant vomiting and most urgent distension. A trochar was plunged into the colon, an escape of gas took place, and relief ensued. She died, however, in eighteen hours afterwards. In another case of internal obstruction the patient survived the operation twenty hours. Would an operation of this description be considered justifiable in this country, merely with a view of relieving symptoms, the termination of the case being certainly, either way, fatal ?

Mr. Benjamin Phillips regarded the paper as a very important one. The operation had been performed many times, with various success, both for obstructed bowels and imperforate anus. As far as he knew it had been generally unsuccessful. The operation itself was by no means a difficult one, the real difficulty in these cases being to determine the circumstances which justify the proceeding. On what did the obstruction depend ? Cases of obstruction presented themselves, dependent on the collection of hardened feces, in which the patient became emaciated, and the symptoms presented all the appearances of internal strangulation, yet these cases were relieved without operation. If the obstruction were the result of disease in the rectum, as for instance carcinoma—of which disease Broussais was said to have died—there would be little difficulty in detecting its nature, and an operation like that under consideration might be performed with the chance of prolonging life, but even here we only substitute one infirmity for another, and it might be questionable which was the most difficult to be borne with. It was when the obstruction was situated higher up that it was difficult to decide on what it was dependent, and in what way we should proceed. The contraction, in fact, might exist at the very point at which the operation was usually performed. In Mr. Evans's case there was no indication presented to warrant us in drawing a conclusion as to the precise cause of the obstruction. Indeed, from the occasional passage of clay-coloured feces, it might have been diagnosed as arising from fecal accumulation, instead of being, as it was afterwards found, a stricture of the colon.

Dr. Powell remarked that it was surprising how long constipation might exist in hysterical patients. He related the case of a lady who was constipated for three weeks, and who was relieved by the use of opium and croton oil. On one occasion she had no evacuation for two months. Injections were of no avail, and she took as much as half a grain of morphia and two drops of croton oil night and morning. In this case he believed the obstruction to be dependent merely on hysteria.

Mr. Davis related the case of a man who had been invalided from the West Indies,

and whose bowels were moved only once in three weeks. His health was good ; but he was occasionally subject to spasmodic pain in the abdomen. Extract of colocynth with opium was given without effect, and he then took a gamboge pill three times a day, with small doses of Epsom salts. This usually succeeded in procuring an evacuation containing a great number of scybalæ every three weeks. The only unpleasant symptom under which he laboured was occasional attacks of spasmodic colic. Under this treatment his appetite improved, though he would now and then reject his food. He detailed another case of constipation following parturition, in which an evacuation, when it was obtained, was found to contain a great number of scybalæ. He mentioned these cases as illustrative of the effects of proper treatment in prolonged constipation.

Mr. Solly agreed with Mr. Phillips as to the difficulty of determining the cause of obstruction in cases of prolonged constipation. Every surgeon in practice must have experienced this difficulty. He recollected a case which occurred some time since of a woman who was tapped for what was supposed to be ascites, but which was found after death to be simple distension of the colon with feces, the result of scirrhus of the rectum. He particularly referred to those cases of internal obstruction which resulted from the passage of adhesive bands from one portion of intestine to another. Some years since he had seen a case of this description with Dr. Sutton of Greenwich. He (Mr. Solly) had been called on to pass a rectum bougie in a case of obstinate constipation. This was readily done, no impediment to its passage being encountered. The patient died four days afterwards. A band of adventitious membrane was found extending from the colon to the mesentery, completely binding down the former, and obstructing its canal.

Dr. James Johnson considered that in Mr. Evans's case there was little difficulty in deciding at what point the obstruction existed. The fact of the bougie having readily passed, combined with the ready injection of three pints of fluid, and the position of the distension, indicated that the obstruction was near the *caput coli*. The operation he considered to have been perfectly justifiable. It was astonishing how long fecal accumulations might exist without seriously affecting the general health. He had a patient at present under his care who had not passed any feces by the rectum for the last three months. He was suffering from a large inelastic tumor near the *caput coli*, and daily vomited up fecal matter. His appetite was good, his general health unaffected, and there did not appear to be any signs of a fatal termination. It might be a question how far an operation in this case might be advisable.

Mr. Dunn related the case of a child who was born with imperforate bowel, the obstruction being situated so high up that a bougie could not reach it. No operation was performed, and after death the colon was found to be not larger than a crow-quill.

Mr. Blizard Curling observed, that it was by no means an easy matter to reach the colon by operation, particularly in infants, and when that canal was undistended. He related a case in which this was attempted; the surgeon, however, cut down upon the kidney. In a case of imperforate anus, in which attempts to reach the rectum were fruitless, he advised the operation of Amussat; but it was not acceded to. After death, however, he (Mr. Curling) performed the operation, and found it less easy, than some gentlemen would appear to think it. By cutting a little too near the spine he came upon the kidney, an accident which he believed had occurred on more than one occasion when the operation had been performed on the living body. When the colon was distended, and the incision was made a little more externally, there would be no difficulty in reaching the intestine. He agreed with Dr. Johnson that in Mr. Evans's case the cause of the obstruction was sufficiently evident to justify the operation. This case, indeed, offered a sufficient encouragement to other surgeons to resort to this proceeding, particularly in those cases in which the obstruction was as evident as in this instance.

Dr. Taylor remarked, that as Mr. Evans was clear in his opinion as to the seat of the obstruction in this case, the operation was justifiable, and had undoubtedly prolonged the life of the patient. There was nothing in the paper to show the nature of the obstruction—whether it was carcinomatous or otherwise. The microscope probably would be the only means of deciding this. It would appear, however, from the history of the case, that it had originated in simple inflammation. It appeared that the patient had for some years been subject to diarrhoea; this was probably the result of inflammation, which had afterwards proceeded to ulceration, cicatrization, and contraction. He had seen similar cases of contraction from ulceration the result of fever, though not always situated in the same spot. In most of these cases no operation had been contemplated, and the patients had died from chronic peritonitis before the obstruction had continued sufficiently long to warrant any operative procedure. He thought that one mode of distinguishing whether the obstruction depended simply on the accumulation of hardened faeces or on structural disease, would be to determine whether the patient had previously suffered from inflammation of the bowels. If so the obstruction was probably structural. He had seen these obstructions in the small intes-

tines frequently follow fever. They were the result of ulceration, cicatrization, and subsequent contraction.

Mr. Hilton considered that in Mr. Evans's case the treatment with respect to the operation had been most judicious. The position of the obstruction was obvious, and the operation was therefore justifiable. He referred to cases of obstruction in the intestines resulting from a twisting of the colon upon itself, and of which he had lately seen an instance. The operation of Amussat was proposed, but not performed. After death a vertical incision was made in the line of the abdominal muscles from the false ribs to near the crista ili: there was no difficulty in reaching the colon by this proceeding. The cases mentioned by Sir George Lefevre, in which the peritoneum was punctured, were very different from those under consideration, in which it was the object of the operator to avoid wounding that membrane.

Dr. Watson, from all he had seen or heard on the subject, had come to the conclusion that the question of the operation was to be decided by the special circumstances of each case. In a case like that of Mr. Evans the operation was justifiable, provided the patient had been acquainted with the nature and consequences of the proceeding previously. Other cases might occur, like that related by Dr. Johnson, in which, however inconvenient, it would be considered advisable to allow faecal evacuations by the throat, rather than resort to the formation of an artificial anus. Other cases would occur in which it would not be possible *à priori* to decide whether an operation were advisable or not.

ROYAL INSTITUTION.

On Friday, April 4th, Mr. S. Solly, Assistant-Surgeon to St. Thomas's Hospital, gave a lecture on the "*Protective Apparatus of the Brain and Spinal Cord in Man and Animals.*" The lecturer pointed out the necessity for an important organ like the brain being protected from external violence, and adverted to the wise provision of nature in enclosing it in a rounded osseous cavity, so that on every side it presented in its form the mechanical advantages of the arch. The structure of the external table was fibrous, and well fitted to resist sudden shocks. In the cavity of the skull the different parts of a soft organ like the brain were in some measure insulated, and prevented from pressing unduly on each other by the processes of the dura mater, the falx major, falx minor, and tentorium. With this mechanical disposition, the head might be moved about freely, and even sustain some violence, without having its structure deranged. In the young the bones of the skull are highly

elastic: they readily yield to shocks; and a blow, which would have the effect of stunning an adult, passes off unheeded by a child.

Another point to be considered, was the means taken to prevent the effect of undue excitement in the circulation of blood through the brain. This organ, it is well known, is abundantly supplied with blood by means of the carotid and vertebral arteries. The carotid arteries take a very tortuous course through a bony canal, and thus, under great excitement, the too rapid supply of blood is impeded,—a fact made evident by the violent pulsations of the vessels on the outside of the head and neck. In the cat tribe, the internal carotids divide into numerous branches about the sella turcica, forming a network or diverticulum of vessels, called rete mirabile. These afterwards unite and form a trunk, which then divides again, and is distributed through the brain. This kind of arterial reservoir prevents any surplus blood from being thrown too rapidly on the brain under violent muscular exertion, as when these animals spring on their prey or throw themselves from a great height.

Some remarks were made on the mechanical form of the spine, its curved shape being so adjusted as to allow it to receive or resist shocks like a doubly-bent spring. The bony protection for the spinal marrow and nerves, and the manner in which great flexibility and freedom of motion are combined with great strength in this part of the skeleton, were also pointed out. The lecture was illustrated by a number of well-executed drawings.

TRIAL FOR WOUNDING.

[THE following trial is of interest in relation to the manner in which wounds may be produced.]

Midland Circuit.

Warwick, Wednesday, April 2.

Joseph Ankers, aged 36, was indicted for having, at Birmingham, on the 24th of December last, feloniously stabbed, cut, and wounded Edward Perry, with a certain sharp instrument, to wit, a penknife, with intent to do him some grievous bodily harm; the indictment charging, as usual, the intents to murder, maim, and disable.

The prosecutor, it appeared, had grossly insulted, and also assaulted, the prisoner's sister. The prisoner resented this, and a scuffle ensued, when he was seen to have in his hand something that looked like the hasp of a penknife, and a penknife was afterwards found upon him. The prosecutor received a clean cut, as from a penknife, two inches long, and one deep; but he had fallen, and there was some broken crockery lying about the place where he fell.

For the defence, it was urged that the wound and other cuts were not inflicted with the knife, but by the fall among the broken crockery; but

Mr. Justice Maule, in summing up, told the jury that all the evidence was dead at variance with this supposition, and it might as well have been urged that he cut himself by tumbling upon an apple or a pound of butter.

The Jury returned a verdict of *Guilty*.—*Times*.

MALAPRAXIS IN MIDWIFERY.

ALLEGED MANSLAUGHTER.

Norwich Lent Assizes.

RAYMOND GACHES, aged 48, was indicted for that he, being an apothecary and man-midwife, so negligently, carelessly, rashly, and feloniously conducted himself in his attendance on one Jane Mary Lovett, in her delivery, as to inflict divers mortal wounds on her body, whereof she died on the 9th of January last, at Costessy, in this county.

Mr. Evans and Mr. Palmer appeared for the prosecution; Mr. Prendergast and Mr. O'Malley defended the prisoner.

From the evidence of Honor Mortar and other witnesses it appeared that Mrs. Lovett had had nine children before the occasion which terminated fatally, and that on former occasions a difficulty had presented itself in the removal of the placenta, the danger from which was well known by medical men to increase with each labour. On the 19th of January the poor woman was taken ill, and the defendant called in to attend her at 11 o'clock. For some time the difficulty anticipated did not arise, but it did at length, and the nurses suggested further advice. The defendant, however, declined it, saying that "if there was a room full of doctors they could do no more than he was doing." After this he seemed to be using great exertions with the view of relieving the patient of the placenta, and after a while a round substance came forth, such as had never been seen before by the nurses in their experience, and he was then seen to use his scissors under the clothes. At that instant the features of the sufferer underwent a sudden change and shock, on which the "doctor" observed "she was very sadly, and he would go and fetch some medicine." So saying, he placed the substance above mentioned, and some other thing which he had afterwards taken from the bed, in a vessel, which he took away with him. In the course of half an hour afterwards the patient died in great pain, and, being duly buried, nothing more would, perhaps, have been heard of the case, had not the

defendant, when interrogated by the mother, stated that the substance he had taken away was a tumor, weighing three ounces and a half, and that he had taken it to Mr. Crosse, the well-known surgeon in Norwich. This was for the time satisfactory to the inquirer, but afterwards a suspicion was excited that the defendant had not conducted himself properly towards the deceased; and her body being exhumed under the direction of the coroner, was submitted to examination by Mr. Crosse and Mr. Francis, who ascertained that the uterus and a considerable quantity of the large intestines had been torn away. The evidence of these gentlemen was given to-day to the above effect, and they gave it as their opinion that great blame was attributable to the defendant if the removal of those parts was ignorantly effected by him, and still more so if it had been knowingly done: at the same time, they admitted that the case was not one of every-day occurrence, and that no stronger term than ignorance ought to be attached to his treatment of the patient; while the most skilful surgeons and operators were known to have "made mistakes."

Mr. Prendergast, on behalf of the prisoner, contended that the course pursued towards him was somewhat harsh, as it was unfair to expect from every man embarked in so critical a profession the consummate skill of an Astley Cooper or a Dr. Conquest, whose book on midwifery he largely quoted.

Mr. Justice Patteson, in summing up the case, thought that the question was not whether the defendant wilfully had removed the parts in question, for no man in his senses could do that; but it was for the jury to say whether, under all the circumstances, he had done more than fall into a mistake. *For a mere error of judgment he did not think that a medical man ought to be made criminally responsible, unless he had displayed gross professional ignorance or inattention to his patient.* The nurses all bore testimony to his kindness and attention, and it would therefore be for the jury to say whether they thought he had acted with such gross ignorance as was imputed to him by this charge.

The jury, without much hesitation, returned a verdict of *Not Guilty*.

From the verdict of the jury, given, as it is said, "without much hesitation," it would appear that Mr. Raymond Gaches in removing from a female during parturition the uterus and all the large intestines (see evidence below) did not display "gross professional ignorance or inattention to his patient," the test of criminal responsibility on such occasions, according to the learned judge. This is the third case of "disembowelling" which has occurred in midwifery

practice (!) during the last year. Mr. Gaches is more fortunate than Garland and Gullimore, both of whom were committed and sentenced to imprisonment.

We are indebted to a friend for the subjoined evidence of the medical witnesses given at the inquest at Costessy. We shall return to the subject in a future number.

Post-mortem Examination of a female who died during labour.

Costessy, Feb. 28th, 1845.

William Bransby Francis, surgeon, of Norwich, says as follows:—

I have examined the body shown to me as the body of J. M. L. On opening the cavity of the abdomen, I observed the stomach, small intestines, and bladder; and there was some blood effused into the parts about the pelvis. I took out the small intestines, which had no attachment below; the stomach was then removed, but the large intestines appeared to be absent. The bladder contained about three ounces of urine; the small intestines were then measured, and found to be fifteen feet and eight inches in length. At the lower end the intestines had been torn off. The kidneys were healthy as well as the liver. On removing the parts from the pelvis, I found thirteen inches of the large intestines in the vagina, which was lacerated, but there was no womb. In my opinion death was caused by the injuries inflicted in removing so large a portion of the large intestines and the womb. In the most difficult case of child-birth, there ought not to be any of those parts removed. I never met with a case in which they were removed. In removing these parts I consider there was a great want of skill and judgment. I should think no practitioner at all acquainted with midwifery would remove them; the removal of them would cause almost instant death. I see no reason why after the birth of the child, if proper skill had been used, that the life of the deceased might not have been saved. The length of the intestines in any ordinary case is about twenty-seven feet, or about five or six times the length of the body.

W. BRANSBY FRANCIS,
Surgeon.

John Green Crosse, surgeon, of the city of Norwich, says as follows:—

I have also examined the body shown to me as the body of J. M. L., in company with Mr. Francis. I have heard the whole of his evidence, and confirm all that has been stated in reference to the parts found in the abdomen. The parts entirely absent were the womb with all its appendages; all the great bowel except thirteen inches from the fundament upwards, a small portion also of the small intestines, had been removed with the large, so that altogether many feet of bowel

had actually been removed by the vagina. There was every appearance of the removal having been made by laceration. The removal of the womb and such a quantity of the intestine must necessarily prove fatal. There are no circumstances that would admit of or require the removal of either one or the other. Such an injury could only have been inflicted in error, no circumstance could have required or justified such a practice. I have heard all the evidences, and find that I cannot see any reason why after the birth of the child, if the deceased had been properly treated, her life might not have been spared.

JOHN GREEN CROSSE.

Inquest held by Mr. Pilgrim, one of the County Coroners, February 28th, 1845.

MEDICAL REFORM.

To the Editor of the Medical Gazette.

SIR,

THE disturbed state of the profession renders it incumbent on all who are anxious for its honour and respectability to offer any suggestions that may tend to allay the discontent that prevails, to a considerable extent, amongst a portion of the general practitioners of the country. I therefore request your insertion of the following remarks.

The merits and demerits of Sir James Graham's Bill have been so fully discussed, that extended comments on so hackneyed a theme would scarcely excite the attention of your readers. I shall therefore chiefly allude to the conduct of those general practitioners who have been most conspicuous in their opposition to the measure.

The object of those gentlemen appears to be, either the continuance of the Apothecaries' Company, with their present and perhaps additional privileges, or the formation of a new corporation, consisting exclusively of general practitioners, who shall have the power of framing laws and regulations for the government of this branch of the profession.

Either of these schemes would have the effect, eventually, of separating this class from the College of Surgeons, and it behoves all who are interested in the welfare of their profession to pause before they support a system so calculated to injure its reputation as a scientific body, and lower its estimation in the minds of the public.

A strong feeling of indignation against the Council of the Royal College of Surgeons can alone account for the zeal with which the interests of the Apothecaries' Company are upheld by men, who, till lately, never appeared to set any value on their connection with that body; who went before their

examiners only on compulsion, and because they could not otherwise legally practise pharmacy; who have always been ashamed to assume the title which the Apothecaries' license conferred, and, with few exceptions, have sought voluntarily the diploma of the College of Surgeons, although that document gave them no legal privilege.

This undeniable fact shows how favourable were formerly the feelings of the younger members of the profession towards the College, and should induce them to deliberately consider the policy of their present proceedings, and reflect on the condition in which they will be placed if they sever that connection which has so long subsisted between them and the College of Surgeons.

The members of the College of Surgeons, most of whom are general practitioners, have long complained that they had no voice in the election of the council. This, indeed, has been their chief grievance; but they have never manifested the same desire to assist in the choice of the examiners or rulers of the Apothecaries' Company: a strong proof of the contempt, or, at least, indifference, in which they held that body. It is, indeed, notorious that the Apothecaries' license gives no privilege, except permission to practise pharmacy, as, if the members wish to partake of the trading profits of the company, they must purchase a right to do so, as they would buy a share in a railway, or other joint-stock concern.

If the general practitioners succeed in establishing a new College, or in effecting a change in the Apothecaries' Company, that will separate them entirely from the College of Surgeons; they will be under the government of a few leading metropolitan apothecaries, highly respectable individuals, possessing large fortunes, and the influence which wealth can always command. Many of these gentlemen are active, intelligent, and enlightened practitioners, but I mean no offence in saying that, collectively, they have not attained that eminence in science, or professional celebrity, that ought to distinguish the governing body of so influential, able, and useful a class, as the general practitioners of this country.

I hope, therefore, that these considerations will induce the general practitioners not rashly to dissolve a connection which they have hitherto esteemed, and which they cannot abandon without inflicting irretrievable injury upon themselves and the public. I hope, too, that the Council of the College of Surgeons will relax the measures which have given such offence to the majority of their members, and by a more liberal policy endeavour to preserve that union which is so decidedly advantageous to all parties.

With the view of effecting so desirable an object, I shall make a few remarks on the

charter of the College, and the conduct of the council.

It is generally believed that the new charter of the College of Surgeons was framed in accordance with the opinions of the council of that body. In effecting so important and comprehensive a change in the laws of the College, the council appear to have been desirous to comply, to a certain extent, with the wishes so long and so loudly expressed by the members at large, that the governing body should not be self-elected, nor hold their situations for life: but, as men, either collectively, or individually, do not willingly relinquish power, the council retained most of the privileges which they already possessed, and recommended only that future members of the governing body should be appointed by a more extended suffrage, and for a limited period.

Whatever dissatisfaction may have been produced by the old council's permanent retention of office, it should be remembered that this evil, if it be an evil, will be only temporary, and will cease with their lives. The measure, therefore, is scarcely worthy of the severe reprehension with which it has been treated by some opponents.

The most important feature in the new charter is the division of the members into two classes. The institution of Fellows, who cannot be admitted till twenty-five years of age, will induce the candidates for this class to obtain a more extended preliminary education than the present members generally have received. Indeed, it is probable that, in many instances, a collegiate education will be resorted to, before the commencement of professional studies, and as the latter must be taken out before the mature age of twenty-five, and the fellowship then obtained only after a strict examination, it is evident that this plan will have the effect of introducing into the profession of surgery persons, who, from position and acquirements, will be best calculated to raise its respectability, and advance its knowledge; while the admission of members, at the age of twenty-one, will enable those who do not choose to continue their studies to a more protracted period to settle, and pursue the line of general practice at the earliest possible age.

The charter delegated to the council power to appoint a certain number of fellows from the members at large, to form an immediate constituency for the purpose of electing three additional members of council. It is perhaps impossible to arbitrarily select, for elevation and distinction, a few from a large community, whose privileges, individually, are equal, without the remainder feeling degraded at their omission. It was, therefore, the duty of the Council to perform this task in the way least likely to inflict in-

justice on any one who considered he had a claim to the Fellowship. To have made at once all the members Fellows, as has been proposed by some, would have merely changed a name, and vitiated the whole scheme. The only mode, therefore, which could have prevented any reasonable complaint is that of seniority. If the Council had promoted the senior five or six hundred members to the fellowship, on the condition that they should be succeeded at their deaths, by their juniors, in regular rotation, during the lives of all who may be members at a certain date, and that younger members, who declined waiting their turn of seniority, might obtain the Fellowship by examination, I believe we should have heard but little of the clamour which has been so mercilessly raised against the members of the Council, in regard to the period to which admission to the fellowship by seniority should have been manifested. The bye-laws relating to the fellowship state that new Examiners shall be appointed on or before the 1st day of January 1850, and it is probable that the new regulations will not be in full operation before that period: it would therefore have been proper to have fixed that date as the latest at which Fellowships should be obtained by seniority of Membership. This plan would have prevented any complaint of injustice either by members or by students who commenced their professional studies under the old *régime*. It would, it is true, have excluded from the Fellowship many of the present hospital surgeons, and all those who expect to be their immediate successors; but it is worthy of deliberate consideration how far some modification of the plan might not be advantageously adopted. If a supplementary charter were granted, giving the Fellowship to a few hundred senior members, in regular succession, of all who obtain their diplomas before the 1st of January, 1850, and enjoining that, after that date, none shall be Fellows, except by examination, the present angry feeling of the members would be abated, the merits of the charter would be acknowledged, and the measure would at least receive that calm and dispassionate investigation to which it is entitled.

I have no selfish object in offering these remarks, as I cannot be personally affected by any arrangement that can be made for the government of the profession, and I have no feeling of disappointment, as my name appeared in the first list of Fellows of the College; as, I imagine, from my standing, would have been the case if the plan I have suggested had been adopted. I have reached the period of life that renders it necessary for me to retire from active professional duties; but, nevertheless, I am anxious that the present excitement should subside; and in the hope that unanimity will soon prevail

amongst all classes of the profession, I beg to subscribe myself, sir,

Your obedient servant,
MEDIATOR.

THE SURGEONS' COLLEGE OATH.

To the Editor of the Medical Gazette.

SIR,

IN one of your late numbers there is a letter signed M.R.C.S., from Liverpool, on the subject of the College of Surgeons' oath. I beg leave to give you my thoughts upon it. The writer speaks well of the inviolable obligation of the oath taken by all admitted members, but he does not appear to have considered its application to the Court of Examiners and Assistants, as he has to the ordinary members. Certainly, both the governors and the governed are under the same oath respectively; and if the one party is to be tried by his oath, and the other not, that is a sure way of bringing an oath into desecration and contempt. Now how stands this matter at the College? The member swears, among other things, that he "will maintain the dignity and welfare of the College," &c., including all "the bye-laws and rules." Then let it be remembered that this oath binds him still, if he subsequently becomes promoted to a seat in the court of the College; and what does his oath require him to do when he gets there? See the article, "Rights of Members." "The College will at all times protect and defend every member thereof who shall in any manner be disturbed or interrupted in the exercise of, or be in danger of losing any, of the rights, privileges, exemptions, or immunities, to which, as a member of the College, he is entitled." If the spirit of this article had been faithfully kept, would it not have prevented the present commotions in the profession? Where is the list of complainants (against aggressive brethren) who have been relieved by the protection and interference of the College? The truth is, that there has been no violation of the oath by members joining the National Association of General Practitioners. The great majority of these, when they took the oath, belonged, or intended belonging, to the Apothecaries' Society; and independently of the proposed annihilation of that representative head, they would have a civil right to reorganize, if expedient, that department of the profession under a new name and system without in the least touching their oath made to the College of Surgeons.—I am, sir,

Your obedient servant,
A PRACTITIONER.

April 7, 1845.

HEREFORD MEMORIAL.

*To the Rt. Hon. Sir James Graham, Bart.
Her Majesty's Secretary of State for
the Home Department.*

The Memorial of the Surgeons of the City and County of Hereford.

SHEWETH,—That your Memorialists, Members of the Royal College of Surgeons of England, resident in the city and county of Hereford, in compliance with the oath they have recently taken, on being admitted members of the college, to maintain its dignity and welfare to the utmost of their power, feel it to be an imperative duty respectfully to call your attention to the injustice displayed in the mode of carrying out the charter recently granted to the Royal College.

Your Memorialists cannot but feel, that the Council of the Royal College of Surgeons of England has broken faith with the general body of the members, by the principle of election to the newly created grade of the Fellowship, which it has seen fit to pursue. Full power was given to the Council by the new charter to carry out this principle in a way which would not have interfered with existing rights and privileges, but it has not done so; and further, your Memorialists consider that the course it has adopted is most injurious and degrading to the overwhelming majority of its members, and utterly at variance with those principles of honour and justice which should ever distinguish a Royal College.

Your Memorialists fully recognise the right of merit to the distinction of the Fellowship, but this principle of election can only be justly carried out to a very limited extent, and when it is thought necessary to go beyond this, they are of opinion that the only just mode is then to make "length of standing in the profession" the means of admission for all present members to the Fellowship, (at once, if they have attained the requisite period, or as they respectively do so,) since it is the only plan, which, from its not being retrospective, would prove satisfactory to the members in general, and regain for the Council that perfect confidence which has been so much shaken by a departure from it in the late proceedings.

For these reasons, your Memorialists would humbly but earnestly suggest for your consideration, the propriety of advising Her Majesty to grant a new charter to the Royal College of Surgeons of England, or to sanction such a modification of the present charter as will effectually remove the injustice which has been thus cast upon the majority of the members of the college; or, in the event of neither of these plans being deemed

admissible, your Memorialists would also respectfully suggest for your consideration the propriety of advising Her Majesty to grant a separate Charter of Incorporation for the General Practitioners, as a measure then essentially necessary, in their opinion, for the maintenance of the welfare and prosperity of this most important class of the profession.

[Signed by 43 members of the College, whose diplomas date from 1796 to 1843.]

EXAMINATIONS AT THE UNIVERSITY OF LONDON AND APOTHECARIES' HALL.

THE following returns were obtained by Mr. Christie, the member for Weymouth, of the candidates for medical degrees, and the number who have taken such degrees, in each year since the foundation of the new University. From 1839 up to 1844, 268 persons presented themselves at the first examination for degrees as bachelors of medicine, of whom 176 passed; and 118 presented themselves at the second examination for the same degree, of whom 106 passed. During the same period, 33 persons presented themselves for the degree of doctor of medicine, all of whom passed. The number of colleges in connexion with the University of London appears to be 26, and the number of medical schools recognised by the said University (exclusive of 17 independent lecturers) to 53.

According to the above document, on an average of six years, *i. e.* from 1839 to 1844 inclusive, the following table will represent the results of the University examinations.

For the degree of Bachelor of Medicine.

	Examined.	Passed.	Rejected	Rej. per Cent.
1st Exam.	268	176	92	34
2d Exam.	118	106	12	10

For the degree of Doctor of Medicine.

“ 33 33 “ “

Thus the degree of Bachelor of Medicine has been conferred on 106 candidates, or rather more than 17 per annum; while the degree of Doctor of Medicine has been conferred on 33 candidates, or rather more than 5 per annum. The rejections at the first examination amount to more than one-third of the whole of those who presented themselves; at the second examination, to one-tenth. This result shows that the candidates for the second examination are a superior class of men: the first list of candidates is, in fact, to use a technical term, weeded. There is one singular circumstance observable with respect to the second examination; *i. e.* that the number of candidates who presented

themselves was one-third less than the number who had passed the first examination; for while the former were 118, the latter were 176. It is highly creditable to the candidates for the degree of Doctor of Medicine, that there has not been a single rejection.

In presenting a similar table relative to the results of the examinations by the Apothecaries' Society, we do not intend that any comparison should be drawn; for, not to mention the much better (*i. e.* more strict and practical) kind of examination which takes place in the University, it must be remembered that the University is of recent establishment, and its degrees confer no legal privileges. The examinations of the Apothecaries' Society extend over a period of about thirty years, and its diploma is legally necessary to one who wishes to become, in England, a general practitioner.

Results of the Examinations for the License of the Society of Apothecaries during a period of twenty-nine years, i. e. from 1815 to 1844.

	Examined.	Passed.	Rejected	Rej. per Cent.
Total	11,564	10,033	1,531	
Average number per annum,				
	398	346	53	13

The rejections amount to an annual average, therefore, of 13 per cent. In the number examined are, of course, comprised a large number of the rejected of preceding years.

The Apothecaries' Society differs strikingly from the University, in the fact, that they have gone on the pernicious system of perpetually controlling lecturers as to the number of lectures, and pupils as to the precise time of their attendance, instead of allowing a reasonable liberty in this respect. The University have acted on a different principle; they require knowledge in the candidate, and care little where he obtains it.

RUPTURE OF THE SPLEEN.

A ROBUST man, about 40 years old, was engaged in a scuffle with another of the same size, and received one blow from the fist of his opponent in the left hypochondriac region; the combatants then clenched each other, and so equal were their exertions for five or ten minutes, that it seemed doubtful which would come off victor. At length, however, the strength of J. W. seemed suddenly to fail; he turned pale, staggered, and sunk helpless upon the ground, complaining of nausea, faintness, and pain in the left side. He was carried, in a sinking condition, a short distance to a house, where he expired, in about fifteen minutes after the termination of the conflict.

On dissection, twenty-four hours after

death, no marks of violence were observed on the exterior. The cavity of the pericardium contained about two ounces of effused serum. In other respects the contents of the thorax appeared natural; but, upon cutting through the abdominal parietes, exit was given to between two and three quarts of dark, partially coagulated blood. An extended incision brought into view the spleen, enlarged to about five times its natural dimensions, and so soft in texture as to be easily broken down under slight pressure from a finger. Upon its posterior surface was a lacerated fissure of about five inches in length, extending deep into the centre of the organ. It was evidently from the divided blood-vessels of this torn structure that internal hæmorrhage had taken place to such an extent as to cause immediate death.

The coroner's verdict was as follows:—"Death from lacerated diseased spleen, caused by a blow, fall, or over-exertion, while engaged in a scuffle with B. R." B. R. was tried for manslaughter, and acquitted, by the Circuit Court."—*Dr. Her-rick, in Illinois Med. Journ.*; and *American Journal of the Medical Sciences*.

MALFORMATION OF THE GENITAL ORGANS.

ENTIRE ABSENCE OF THE URINARY BLADDER IN A MAN.

DR. D. ROSS LEITCH had an opportunity of examining a singular case of malformation of the above nature in the person of a man, æt. 39. The man died after fracture of the femur extending into the knee-joint. The body was slight and effeminate; there were beard and whiskers, but only a few scattered hairs on the pubes. His voice had been weak, and rather shrill. There was no appearance whatever of a penis. The man declared that he had once possessed something of the kind, but nothing remained to corroborate the statement. As in the case of Highmore's boy, referred to by Dr. Duncan in the first number of the *Medical and Surgical Journal*, "all was entire and smooth," from the orifice of the ureters to the anus. The testicles were small but natural, similar to the cases mentioned by Dessault, Knox, and others; they were contained in folds of skin near the pubes. As is almost universal in these mal-conformations, the bones of the pubes were separated to a considerable distance from each other, the interval being filled up by a broad strong ligament; symphysis and descending rami of the pubes were wanting. By separating the acetabula and thighs to a greater distance than usual, this had rendered the man's walk less firm than common, and produced a rolling of the body from side to side. The anus was thrown so far forwards that

there could scarcely be said to be any perineum. A slight umbilical scar was visible low down in the hypogastric region, about an inch and a half to the right of the urinary orifice. There was no trace of the corpora cavernosa, or appearance of a scrotum. The epididymis on both sides was very observable, terminating naturally in the vasa deferentia, which, after a brief course, expanded into the vesiculæ seminales, and there, with the prostate gland, were attached to the posterior part of the conjoined ureters. Certain minute orifices, into which a bristle could be thrust, appeared near the mouth of the urinary passage; and these seemed to have given exit to the seminal fluid. The *left* kidney was nearly natural; the pelvis, however, was more capacious than usual, and the ureter on that side was slightly increased in its calibre. In the *right* kidney, the cortical substance had disappeared, and the organ presented the appearance of a globular membranous bag, the sides of which, as well as those of the corresponding ureter, were thick, firm, and condensed in their structure. The *right* ureter was twelve or fourteen lines in diameter. About an inch and a half from its termination on the surface of the abdomen it was contracted so as to perform the office of a valve. Muscular fibres could be traced at this portion of the ureter. Though the urine had continually dribbled away from the unfortunate patient, he declared he was able to expel it from time to time in considerable quantities: there is little reason to doubt the statement, for the right kidney and ureter were found after death filled with urine. Dr. L. thinks it probable that the water which continually trickled from the orifice came altogether, or in great part, from the *left* kidney, there being nothing in the corresponding ureter to obstruct its flow, but that the valve at the lower part of the *right* ureter enabled him to retain the urine in that distended canal, and the capacious pelvis of the kidney, for some time, and that, by the pressure of the abdominal muscles, the membrane at its valvular portion was so far overcome as to permit the discharge of the collected fluid. It seemed to Dr. Leitch a very curious and admirable instance of the ingenuity of nature in compensating original deficiency of structure. There was not the slightest trace whatever of the urinary bladder, but the ureters terminated at their point of junction on the skin above the pubes. There was abundant proof that the man had possessed the sexual appetite. It is also mentioned that the banns had been three separate and distinct times proclaimed at the parish church, between him and a woman who was attached to him.—*London and Edinburgh Monthly Journal*, February.

SEPARATION OF THE CERVIX UTERI IN PARTURITION.

DR. A. DAVIS, of Newry, attended a woman *æt.* 46, of low stature and rather corpulent, in labour of her fourth child; her eldest and her youngest child being still living. The labour was protracted, the uteri being very thick, and dilating very slowly to the size of a crown piece. On the third day it was considered, from examination with a stethoscope, that the child was dead. Anodyne enemata were prescribed; the pains continued, but diminishing in strength, until the morning of the fourth day, when a transverse rent, of about two inches in the cervix uteri anteriorly, was discovered. It was now determined to use the perforator, previous to which Dr. Davis divided the separated portion of the os uteri longitudinally, gave a dose of infusion of ergot of rye; and, after some time, extracted a large female child. The placenta was shortly after removed with little difficulty. She bore the operation very well, and soon after went to sleep. For a few days subsequently the patient suffered from swelling of the abdomen, and from slight bronchitis. On the sixth day after delivery the separated portion of the os uteri, which was very much enlarged, sloughed off. Dr. Davis thinks that two-thirds of the os uteri came away. From this time her convalescence was rapid."—*Dublin Medical Press*, Jan. 15, 1845.

[We should scarcely have ventured, with Dr. Davis, to administer the ergot in a case where any part of the uterus had suffered rupture; still the practice, in this instance, does not appear to have been attended with ill consequences.—*Ed. Gaz.*]

TO CORRESPONDENTS.

Received—Mr. J. Coventry's Remarks on Dietetics, Medicine, &c.; Mr. H. N. Shaw; Prize Clinical Reports of the Queen's Hospital, Birmingham; Dr. Blackmore; Dr. Letheby; Dr. R. H. Allnatt; Mr. George Padley; Thomas Taylor.

A proof shall be forwarded to Dr. Ritchie as usual. His papers will probably be reserved for the New Series.

We shall be glad to avail ourselves of Mr. Erichsen's offer: his contributions will be announced with those of other contributors.

We refer Mr. G. M. Davis to our leading article.

Dr. Rowland's paper is in type, and will have early insertion.

We regret that, owing to the press of matter, we have not been able to find room for many interesting communications; they will be inserted as soon as the state of our columns will permit.

Much credit is due to Dr. Orpen for his ingenious suggestions respecting anatomical

nomenclature, but we do not think that the publication of his Essay in our journal will be attended with any practical good.

Dr. Marsh.—In the New Series the present size of the *MEDICAL GAZETTE* will be preserved: there will be an additional number of pages, and the stamped edition will be transmissible by post, like the other medical journals.

MORTALITY OF THE METROPOLIS.

SOME OBSERVATIONS

ON

TETANUS, OR LOCKED JAW, AND
ITS TREATMENT.

By R. A. STAFFORD, F.R.C.S.

Surgeon Extraordinary to his H.R.H. the Duke
of Cambridge, and Surgeon to the St.
Marylebone Infirmary.

(For the London Medical Gazette.)

OF all diseases yet known, there is perhaps no one the causes of which we have less clear evidence than of tetanus. Much difference of opinion, therefore, has arisen with regard to its treatment. Some have conceived that sedatives are the only remedies to be relied on, while others on the contrary have rather chosen purgatives,—the exhibition of mercury to salivation,—the abstraction of blood to a large amount; with the addition of various other remedies too numerous at present to mention. The opinions, even yet, being at variance as to the nature and treatment of this disease, I am induced, having seen in my practice a few cases, to offer some observations upon it.

Those who have written systematically on tetanus, have distinguished it by two epithets; that originating from wounds they have called traumatic, and that produced from cold, or any other cause, idiopathic. They also have made other divisions of it, according to the particular parts of the body which are affected by it. Where only the muscles of the jaw are affected, they have given it the term of trismus; when the muscles of the back, drawing it backwards, opisthotonos; and when the body is drawn forwards, emprosthotonos; and when to either side, pleurosthotonos. These distinctions, as far as they go, are very good, but they do not explain to us any method of treatment by which we can relieve it.

In trismus, the masseter muscle is chiefly

affected, and is in a constant state of spasm. The jaw is completely closed, and the teeth are usually permanently fixed one against the other. It is impossible to open the mouth; the patient may use all his efforts, but the power is totally gone. In fact, to use the expressive English phrase, he has "the locked jaw." In opisthotonos, the spine is curved backwards, like a bow, but the back is not permanently fixed in this position, as the jaw is in trismus; for there are frequent paroxysms of spasm of the muscles of the back, temporarily increasing the curve. In emprosthotonos, the body is curved forwards, attended with spasm, but, according to my opinion, it does not so frequently take place as the other symptoms. In pleurosthotonos the body is curved either on one side or the other.

Traumatic tetanus mostly occurs after lacerated or contused wounds, and more particularly those of the tendons. Eight days is the period after an accident of this description upon which it is said usually to make its appearance, but it is quite uncertain, for instances have been adduced where it has shown itself much earlier; in some instances it has been known to occur even in a few hours. The first symptoms attendant upon it are a stiffness at the root of the tongue, and of the muscles of the hinder part of the neck, which become rigid, and the cervical vertebrae are rather drawn backwards. From this time the muscles of the jaw gradually contract, the teeth being closed, or nearly so, and there is generally great difficulty of articulation and deglutition. The next symptoms are, either a stiffness of the muscles of the back, or of the abdomen, generally of the former; and last of all, the whole body is affected by violent and repeated spasms, which come on in paroxysms, in one of which the existence of the patient is terminated. Added to these, the bowels are very inactive; the faeces when voided are of an unnatural colour, being, as Mr. Abernethy used to say,

like sloughs, and they are of a very foetid and offensive smell. The tongue is furred, the pulse extremely quick, and the organs of respiration are affected, the diaphragm participating in the disease, as well as the other muscles. The whole body is covered by a profuse sweat, exuding from the surface in large drops. In fact, in the last stages of the disease, there is hardly a muscle of the body which is not affected by spasm. The muscles of the face are distorted, the eyes are fixed, and the lips are opened, causing a peculiar sardonic expression. The muscles of the whole body are in one continued state of spasm. In short, like an earthquake, the whole foundations of the frame are shaken and convulsed. Nature is overcome, yields to the contest, and death ensues. In idiopathic tetanus the same symptoms occur, but the cause is different. It generally arises from internal irritation, such as a worm in the intestines, or from cold, &c.

In speaking of the causes of tetanus, we must take a general comprehensive view. The whole nervous system is involved in the disease, and therefore it cannot be one cause alone which will produce it. There are many. It is evident from the symptoms which occur in this disease that the medulla spinalis, or the medulla oblongata, are affected, and that the functions of the muscles which they govern are deranged. It is indisputably proved that the medulla spinalis sends forth two different set of nerves; the one governing the power of motion, and the other that of sensation. From the phenomena which occur in tetanus it would appear that the motor track itself of the spinal chord possessed two separate powers—a positive and a negative; that is, the positive being the power of contraction of muscles; the negative, that of their relaxation; for instance, if the extensor muscles contract, the flexors relax, and if the flexors contract, the extensors relax, showing an active and consenting function at the same time. In trismus, we find that those muscles of the jaw which shut the mouth are in a fixed state of spasm; no power can open it. The patient wills it, but the digastricus and other muscles which open the lower jaw cannot obey; try how he will, he cannot accomplish his object. This proves pretty clearly to my mind there are two powers. The one to keep the mouth shut, and the other to open it; that is to say, the power of the masseter muscle is increased in tetanus, while the antagonizing muscles are diminished, or have not strength to resist the action of the former. We see the same in opisthotonos; the muscles which keep the body erect, have an increased power, whilst those which bow the body forward have no control over the superior power, and cannot re-

sist the spasmodic rigidity of the former. In emprostotonos, those which bend the body forward are the strongest, proving that that point of the motor tract which supplies these muscles with nerves is most affected. It appears to me, therefore, in the natural function of the muscles, that when one set of them act, there is a consenting power in the opponent muscles to allow them to do so; for instance, when the mouth opens, which is performed by the digastricus and other muscles, the masseter permits it, and relaxes, and, on the contrary, when the mouth is shut, the former relax, and the masseter contracts, and so throughout the whole body. But we do not see this in tetanus; we observe an increased power in one set of muscles, while the others have none. It is evident, therefore, that the equilibrium of the two powers are not natural; the one is so great that the other is rendered quite ineffectual.

But, in speaking of the cause of tetanus, we must not forget the sympathy which must naturally subsist between the extremities of nerves and their origins; for instance, a worm in the intestines will so much irritate the extremities of the grand sympathetic nerve that it will produce such a state of diseased action at its origin as to induce tetanus. Again, if the tendons be wounded, they will do the same, they being the termination of muscles. In speaking of tendons we must recollect that each is the condensation of a whole muscle. Consequently, if one tendon, or more than one tendon, be lacerated, what a derangement must it naturally cause in the function of the spinal chord, which has been accustomed from the beginning of the formation of muscles to govern their action! The equalization of their movement, however, is broken; some muscles can obey, while others cannot. The regularity of their action simultaneously together is at an end, and their natural function is destroyed. That a sympathy exists between the tendons and the spinal chord there can be but little doubt; but what that sympathy may be it would be difficult to define; nor can we know the effect which might be produced on the grand nervous trunk or centre by the sudden loss of power of some of the parts which it has governed.

But, to continue the argument, we must go to the symptoms which appear in epilepsy, chorea, and other nervous affections. In epilepsy, it often happens that partial trismus is produced. There is gnashing, and sometimes a complete closure, of the teeth, but it is not permanent, as trismus is in tetanus; the jaw relaxes. In chorea, it is evident that portions of the motor tract are affected, but in what manner exactly we cannot tell. It would appear, however, that

the spasm of the muscles arose more from weakness than too much power. The very opposite occurs in tetanus to that which takes place in chorea. There is a confirmed spasm in the one, while in the other it is uncertain and unfixed,—a spasm more of weakness than strength. Perhaps the nervous influence to one set of muscles is not as strong as to the other, whereby their equilibrium is lost, and the balance of power between the two is unequal. The treatment of chorea proves to us that the disease arises from want of tone.

In addition to the discoveries of the late Sir Charles Bell, Dr. Marshall Hall has thrown considerable light on the functions of the medulla spinalis. He considers there is a reflex function in the spinal chord and its nerves, and in the parts they supply—that is to say, quoting his own words, “it acts in direct lines along the spinal marrow, and from the trunks to the branches of nerves, and from the muscles they supply;” and also, “it acts in reflex directions to and from the spinal marrow; that is, from peripheral, cutaneous, and mucous surfaces, through the spinal marrow, to the coordinate muscles, according to a newly discovered law;” also, “it acts in a retrograde direction along the spinal marrow:” but for more information on this subject, I beg to refer my readers to Dr. M. Hall’s Memoirs, in the Royal Medical and Chirurgical Transactions, Vols. IV. V. and VI., 2d series.

That in tetanus there is a reflected irritation there can be but little doubt; for instance, a boy receives an injury on the first joint of the great toe, as in Case IV. In seven days trismus supervenes. Here we see that, from the most remote extremity, the medulla oblongata becomes first affected, and produces a permanent spasm of the masseter muscle, so as to firmly and completely close the mouth. It would have been natural, the injury occurring in the foot, to suppose that the lower part of the spinal chord would have been first affected; instead of which, that part which is farthest from the seat of irritation suffers, and causes spasm of those muscles which it governs; consequently, the impression of the reflected irritation must have passed through the whole course of the spinal chord, before it reached the medulla oblongata, to have produced its morbid functions. It is a remarkable fact, that in true tetanus, from whatever part of the body the injury or irritation may be, that trismus is first induced, and so on downwards, gradually giving rise to opisthotonos, emprosthotonos, &c.

In all the researches in tetanus the absorbent system appears to have been overlooked. In hydrophobia, the symptoms of

which nearly correspond with those of tetanus, we know that it is caused by a certain morbid virus from the bite of a rabid dog, which becomes absorbed into the circulation. In many cases of this disease the absorbents can be seen in red lines in a state of inflammation. Mr. Abernethy, I remember, used, in his lectures, to speak of a remarkable instance—to hear so great a man relate a case was of the deepest interest. A man had been bitten in the hand by a mad dog, and Mr. A. watched the case. The absorbents gradually became inflamed in red lines up to the axilla. A basin of water was then shown to the patient, at which he expressed the greatest horror. His horror of fluids continued; he was convulsed at seeing them, and was never able to swallow. He died in three or four days afterwards. In some cases, however, the absorbents are not seen to be inflamed, and the disease does not show itself until months afterwards. Whilst I was house-surgeon to St. Bartholomew’s Hospital the following case occurred:—

A boy was bitten by a dog that was supposed to be mad, and it was killed. The wound healed, and nothing more was thought of it. In six months afterwards, however, symptoms of hydrophobia came on. He had the greatest horror of water, and was convulsed in the most violent manner if any attempt was made to make him swallow; he was thrown into convulsions even if a mirror was shown him. He died with all the symptoms of tetanus, opisthotonos being complete. In hydrophobia we know that tetanic symptoms are produced by a morbid poison being absorbed into the circulation. In tetanus we have no evidence of this; at the same time, however, there is a possibility that a wound of certain parts may secrete such virus that may be absorbed back into the circulation, and produce it. I am led to think this possible, because we frequently see inflammation of the absorbents from irritable ulcers; it is called irritation, but I very much doubt whether the ulcer does not secrete a morbid or acrid matter, which is taken up by the absorbents, causing their inflammation, and that of the glands connected with them. We know this to be the case in syphilis, in dissection-wounds, &c.,—there is a positive virus absorbed. I am not certain, therefore, whether some sores do not secrete an acrid matter, which sometimes is taken up by the absorbents; and although it may not be a specific poison, yet, from its irritating quality, it causes inflammation, and even abscess, in the gland affected by it. But if such should be the case in tetanus, and it is so in hydrophobia, the matter secreted and absorbed must be of so subtle a nature that it even does not cause inflammation of the absorbents as it passes through

their tubes or canals. That tetanus can be produced by certain poisons is a well-known fact; for instance, strychnine will produce it. Mr. Curling, after "the division of the medulla in the dorsal region of a rabbit, inserted this poison in a wound on one of the hind legs, and, in the struggles which preceded death, saw all the four extremities thrown into spasm." He quotes Professor Emmert, of Byrne, who saw the same thing from strychnine, and also found that the false bark of *Angustura* wood would produce universal tetanus if either administered internally, or introduced into a wound.

In the work of Mr. Blizzard Curling—a work of great labour and deep research, of the highest talent, and containing all the literature of this disease—it appears that every means have been taken to discover the cause of tetanus. The nerves of the injured part have been dissected, and they usually have been found inflamed and swollen; they have been traced, also, in some instances, up to the spinal chord, and sometimes along the nerves connected with the wound; the inflammation has extended, either in the substance of the nerve, or along its sheath, continuously, or in patches, up to the spine. The general opinion of those who have made these dissections is, that the nerves of the wounded part are more or less inflamed. M. Pelletier is of opinion that in all cases of tetanus the neurilemma of the nerves going from the injured part is inflamed, and extends on through their course to the medulla spinalis and its membranes, and he has adduced a few cases to prove this. Such opinions would be more tenable if these appearances invariably occurred, but in some cases no morbid change whatever of the nerves has taken place.

The brain has been minutely examined, but nothing more than a general turgescence of that organ and its membranes can be found, and frequently also engorgement of blood in its sinuses. The medulla oblongata, and the spinal chord, have undergone minute research, and upon the morbid appearances of these parts much difference of opinion exists. Mr. Curling and others are doubtful whether any change of structure or other lesions are invariably found. As far as my own experience has gone, there has been always an evident alteration of these parts, and I shall therefore at once proceed to those dissections I have seen, and of which I took notes at the time. Some years ago, a case of traumatic tetanus occurred in St. Bartholomew's Hospital, and I was present at the examination of the body. The brain and spinal chord were dissected. On removing the upper portion of the skull from the dura mater, that membrane was found to be in a high state of vascularity. The arachnoid membrane and the

pia mater were in the same state, and the vessels of the substance of the brain itself were tinged with blood. The appearance of the theca vertebralis also corresponded with the dura mater, and there was considerable effusion under it, and along the whole course of the canal of the spine—so much so that on removing the brain a great quantity of serum flowed from the foramen magnum. The vessels of the spinal chord itself, and the membranes which immediately surround it, were in like manner injected with blood. The dura mater was extremely turgid, and the arachnoid membrane and pia mater highly inflamed, with deposits of lymph upon their surfaces. The intestines, also, were loaded with fecal matter, and had an inflammatory appearance throughout their whole course. In the following case much the same appearances in the spinal chord presented themselves.

CASE I.—S. G., æt. 14, was burnt on the buttocks, back part of both thighs, and penis and scrotum, by his clothes taking fire while attending a brick-kiln. The injury was so severe as to produce the death of the integument far beneath the skin over the greater part of that surface. Considerable coldness and collapse took place immediately after the accident, from the effects of which he was rescued by warmth, brandy, and a large dose of opium. Sufficient purgatives were administered as soon as might be; at first, saturnine lotion, warm, and afterwards turpentine liniment, were applied to the wounds. He did not complain of extraordinary pain for some days, nor was there much excitement; a good deal of suppurative action, and some granulations, arose, and the discharge was copious and healthy.

On the evening of the 6th of May, he complained of some difficulty of swallowing, and considerable tightness and spasmodic contractions of the muscles of the left side of the neck; he was able to swallow then nearly as much as usual. Pulse 80; bowels open; tongue foul, and rather dry; pain of the wound kept him from sleeping last night.

A large number of leeches were applied to the spine of the neck and upper part of the back; large doses of calomel, and calomel and opium at bed-time.

On the following morning, after a tolerable night, the muscular contractions increased, and the head was forcibly drawn backwards, and to one side. Pulse 100; tenderness of the epigastrium from contraction of diaphragm.

On the next day everything worse. Pulse 140; more rigidity of muscles; jaws closed.

Repeated leeches, and cupping on the spine, and calomel and opium, persisted in.

In the evening the respiration had become

affected. Pulse 160 and 180, with occasional spasm of the long muscles of the spine, producing a degree of opisthotonos. Died at 11 P.M.

Section Cadaveris 12 hours after death.

External veins about the spine, particularly the cervical and dorsal portions, excessively loaded with blood, though the body had been for some hours on the face; dura mater of the chord of a darker purple hue throughout than natural, with vivid red blushes here and there; arachnoid membrane of cervical and upper dorsal part exceedingly vascular, so much so as to be quite red in places, and between these the vessels were numerous, long, large, and tortuous. No change could be perceived in the pia mater, but there was effusion of serum between it and the arachnoid membrane. On dividing the substance of the chord itself, the medullary matter seemed darker than usual, and the transverse sections exhibited numerous bloody points from the divisions of the turgid vessel which had pervaded it. In this case it is evident that the spinal chord and its membranes were inflamed, and that even the substance of the medulla spinalis was congested. The following is another case of the same description.

CASE II.—Thomas Billings, æt. 25, fractured the ring-finger of the left hand from a squeeze by a door. It occurred in the second phalanx, and was compound. The tendons and the integument were much lacerated.

On the eighth day he was seized with the following symptoms. He had tension and rigidity of the muscles of the neck and back, with slight but evident curvature backwards. There also was trismus, which, however, was not quite complete, as he could separate the teeth a little. There were slight spasms in the affected muscles. He complained much of a difficulty to expectorate, which was more distressing as there was a great secretion of mucus from the lungs. His deglutition was not at all impeded. His bowels were very costive, not having had a stool for four days. Pulse 110, full, hard, and incompressible; urine natural; breath foetid.

He was ordered—1 grain of calomel, and 8 grains of jalap, to be taken every three hours, and to have an enema containing four drachms of spirit of turpentine.

As the state of the finger was such as to preclude all possibility of saving it should the man recover, and as the amputating the injured limb has been advised by some, the finger was taken off at the second joint.

11 o'clock P.M.—The clyster returned

with a small quantity of hardened fæces. He said he was easier.

On the second day, at 7 P.M., the spasms were not so violent, but the rigidity and tense state of the muscles were still the same. He complained very much of inability to expectorate, and of sneezing, which he said prevented him from sleeping soundly. He had some tightness at the sternum. Had a copious foetid dark-coloured stool at midnight, and a scanty one afterwards. Pulse 115, and hard. Had taken four powders. They were ordered to be continued, and the turpentine enema to be repeated. At 2 o'clock P.M. had a stool after the enema, and was much better. Could open the jaw half an inch. Spasms rather abated.

A physician now saw the patient, and advised five grains of Dover's powder every three hours, and a common enema at night.

9 P.M.—The Dover's and purging powders had been exhibited regularly, but the bowels had not acted since the last report. Spasms were violent; other symptoms not altered.

4th day, 10 P.M.—No stool since yesterday morning. Pulse 120; symptoms the same.

A compound senna draught was ordered.

2 P.M.—No stool; symptoms gradually getting worse; great expectoration.

4th day.—All the symptoms much worse. He wishes to be left quiet.

9 P.M.—Opisthotonos and trismus complete. Pulse quicker, 140; great anxiety; no stool.

Turpentine enema and purgatives now ordered.

5th day, 11 P.M.—Spasms had increased in violence and frequency. The rigidity and tension of the affected muscles extreme. He was covered by a profuse perspiration, and was perfectly sensible.

5 P.M.—He had a tobacco injection, which returned immediately, and after this one composed of brandy. About 7 P.M. he died convulsed.

Post-mortem.—The theca vertebralis was greatly distended by a greenish fluid. The arachnoid membrane and pia mater throughout highly reddened, and upon the surface of the former were found, here and there, extensive patches of lymph, which had coagulated. The vessels of the spinal chord were extremely turgid, and a redness pervaded its substance not natural to this organ.

In this case, as in the last, the membranes of the spinal chord showed evident signs of inflammation and its consequences; and the substance of the medulla itself was more turgid and red than natural.

The case I am about to relate might be

termed arachnitis; that is to say, according to the view M. Ollivier takes of the disease. I have but little doubt that what he has termed arachnitis spinalis is the same as we term idiopathic tetanus. The only difference I can see is, that in true tetanus there are regular stages of the disease—trismus first, opisthotonos, &c.; while in arachnitis the disease originates at any portion of the medulla spinalis.

CASE III.—A man was admitted into the St. Marylebone Infirmary, who gave the following history of himself:—Two days previously he had been lying on his back on the damp grass, while at the same time the sun was extremely hot. In the evening of that day he felt himself very unwell, and went to bed early. On the following morning he found the muscles of the back, and on the posterior part of the neck, very stiff. The symptoms gradually increased until the day he was admitted into the Infirmary, when he was in the following state. He had pain in the whole course of the spine; his pulse was about 100, rather full and hard; the skin hot and dry; the tongue coated with a brown fur; he felt great thirst, and his bowels were costive; the muscles of the back and neck were rigid, and the whole spine was fixedly curved backwards. He was bled to syncope, and ordered five grains of calomel and twelve of jalap to be taken immediately. In the evening trismus came on, and he was seized with paroxysms of spasm; these continued all night, being unalloyed by opium, and on the following day he died.

Post-mortem.—On opening the spinal canal it was found that the arachnoid membrane was in some places reddened, and in others opaque; there was a deposition of lymph, of a tough consistence and a yellowish colour, on its whole surface; and in the centre of the dorsal region, about three inches in extent, blood, which was dark-coloured and coagulated, was effused. The whole canal between the arachnoid membrane and pia mater was filled with serum, opaque, and of a reddish hue, having been tinged by extravasated blood. Nothing remarkable was observed in any other part of the body.

The symptoms and morbid appearances of the following case very much resembled those of hydrophobia.

CASE IV.—On Nov. 10th, 1844, Thomas Smith, æt. 14, was admitted into the St. Marylebone Infirmary with an injury of the great toe of the left foot, which had occurred four days previously, owing to a fall from a horse. There was a deep cut immediately over the first joint, and the part was greatly swollen, and looking red. Leeches and poultices were applied, and the wound appeared to be going on well, when, on the seventh day, he complained of stiffness of

the neck, which he ascribed to a cold. On the following morning his mouth became quite closed, and trismus was complete, with a bending backwards of the cervical vertebræ. He could speak distinctly, although his mouth was firmly shut, but he could not swallow, for when an attempt was made even with a tea-spoon to feed him with milk, it was convulsively thrown back, as in hydrophobia; and he had a dread of fluids, endeavouring by his hands to prevent the nurse from attempting to pour them down his throat, and if persisted in it immediately caused convulsions. His pulse was feeble, and at 140; and there was a profuse sweat on the face.

An incision was made into the erysipelatous swelling around the wound, and blood and pus escaped. He was ordered—

Six leeches to be applied as near as possible at the entrance of the spinal chord, through the foramen magnum into the brain; and the extract of belladonna to be rubbed along the whole course of the cervical vertebræ, and to be frequently repeated. Also, a clyster containing spirit of turpentine and castor-oil of each half an ounce, and forty minims of tincture of opium.

R Hydr. Submur. gr. ij.; Pulv. Jalap, gr. vi. M. ft. Pulvis, in melle tertius horis sumendus.

R Tinct. Cannabis Ind. ℥xx.; Mist. Camphora, ʒj; M. ft. Haustus sextis horis sumendus.

None of these medicines could be swallowed.

He gradually got worse, but the convulsions were most severe. He was ordered a turpentine fomentation to the abdomen, and

R Acid. Hydrocyanici, ℥ij.; Sol. Morphiae Bicar. ℥xxx; Mist. Camph. ʒj. M. ft. Haustus, statem sumendus et repetatur quartis horis.

This draught was convulsively rejected. The breathing now became very difficult, and in twenty hours from the time he was first attacked he expired.

Post-mortem.—Nothing remarkable in the brain itself, but the base of the cerebellum, the tuber annulare, and the medulla oblongata, were much redder than natural. The spinal chord also, along the cervical vertebræ, was redder than it ought to be, but the rest of the medulla healthy. The arachnoid membrane of the base of the brain and spinal chord in the cervical portion injected with blood. There was inflammation of the trachea, of the larynx, and pharynx.

These cases, together with others I have seen, without taking notes, lead me to think that the motor track of the medulla oblongata, and spinal chord, are affected in

tetanus. I am borne out in this opinion by other writers. Dr. Reid has written a treatise on tetanus, and has detailed cases where the morbid appearances of the spine were similar to those I have just mentioned. He also mentions another case, where the spinal chord was equally affected. "There was a great quantity of water found between the vaginal ligament and dura mater, and a considerable quantity also was effused between the latter membrane and the pia mater. Inflammation also existed in many parts of these membranes." In a paper in the *Edinburgh and Surgical Journal*, written by Dr. Saunders, there are some very interesting and satisfactory remarks on this disease, and the spasm of muscles. They are as follows. "That if any muscle, voluntary or involuntary, is affected with spasm, and during this affection the person dies, on examination it is found that the nerves which supply the spasmed muscle are covered with turgid red vessels at their visible origins, or where they appear to set off from the brain, medulla oblongata, or spinal marrow." These appearances, he remarks, invariably occur more or less according to the violence of the affection; that the nerves supplying those muscles which are not affected are perfectly healthy. When speaking of tetanus, he makes the following observation. "If the tetanic affection is confined to the jaws, certain nerves arising from the tuber-annulare and medulla oblongata are found in the state above described; but, if the tetanic affection involves the whole inferior extremity, and the trunk of the body, as well as the jaws, then the origins, from the tuber annulare to the cauda equina, are covered with turgid, or red vessels. In short, the nerves exhibiting such turgescence at their origins, correspond in number and situation with the muscles that have exhibited inordinate spasms or contraction." These investigations were carried on by Dr. Saunders for no less a period than sixteen years, and he did not meet with one exception. In the *Medical Repository*, a periodical which is now defunct, my late much esteemed friend, Mr. T. Brayne, of Banbury, a gentleman of the highest professional talent and character, published some most interesting dissections of two cases of tetanus which fell under his observation. From these dissections, he made two beautiful drawings, and from which a plate was struck, accompanying the history of the cases. In one case was observed a very turgid state of the venous system of the spine throughout its whole extent, in many parts approaching to purple. The arachnoid membrane also was in its whole extent much more vascular than usual, gradually increasing to redness, from above downwards. In the other case, several

inches of the spinal chord were studded with laminated depositions on the arachnoid membrane, and all the vessels of the pia mater were very turgid and tortuous. In the museum of St. Thomas's Hospital there are two or three preparations of the spinal chord, where the arachnoid membrane is covered with flakes of bony matter, and Sir Astley Cooper informed me that the patients from whom they were taken died tetanic.

It is a well-known fact that horses are extremely liable to tetanus, and it may be interesting here to show the analogy which subsists between the human subject and this animal in this disease. Mr. T. Brayne had the opportunity of opening the spinal canal of a horse which died of traumatic tetanus; the arachnoid membrane of the whole spine, but more particularly the cervical and dorsal portions, were inflamed, but there were no depositions upon it.

That irritation and pressure on the spinal chord will produce rigidity and spasm of the muscles, has been shown by Dr. Wilson Philip. In an experiment he made on the spinal chord of a frog, by applying strong stimuli to it, he found that strong and repeated contractions were excited in the hind limbs as long as the stimulus would produce the effect. He also proves this by other experiments, but in one more particularly than in any, where he mentions one form of the disease, *opisthotonos*. His words are these: "The convulsions excited by opium always assume the form of *opisthotonos*. The animal becomes rigid, and is bent backwards. During the intermission of these convulsions the slightest touch renews them. If the animal is allowed to remain undisturbed, they but rarely occur. By frequently touching it a constant succession of them may be kept up." Such an experiment as this cannot be considered any other than satisfactory.

As yet there does not appear to have been any fixed principle of treatment of tetanus; one plan has been pursued by one individual, another by another, without any particular reason being assigned for it. Hence we see that bleeding to a large amount has been adopted, amputation of the limb, division of the nerves, cold affusion, vapour and warm baths, and counter-irritants employed. Numerous remedies also have been administered, such as purgatives of every description, mercury to salivation, opium, and other antispasmodics. The tincture of Indian hemp, (tobacco and turpentine, in injections), antimony, carbonate of iron, hydrocyanic acid, tonics, and stimulants, with a host of other remedies too numerous to mention.

Among the most rational treatments that have been adopted, is that by Mr. Abernethy, and which was founded upon prin-

ciple. He conceived that the disease arose from a peculiar state of the digestive organs, and that the secretions were not natural, being more like sloughs or pitch, than healthy feces. For this reason he formed the idea that if the alimentary canal could be gradually evacuated of its contents, the disease would disappear. With the view of effecting this, he prescribed one grain of calomel, and six grains of jalap, to be taken every three hours. This powder was mixed in honey on treacle, and smeared, as well as the closure of the teeth would permit, upon the back part of the tongue, and it became gradually swallowed. The bowels at length acted, and the treatment was continued as long as any tetanic symptoms remained. Having been Mr. Abernethy's pupil, his dresser, and afterwards his house-surgeon, I had frequent opportunities of witnessing the treatment, and, in many instances, it succeeded. It may perhaps be interesting here to relate from memory some of the cases.

A man was admitted into St. Bartholomew's Hospital, under Mr. A., with a compound fracture of the metatarsal bone of the great toe. In seven or eight days afterwards trismus came on, with stiffness of the muscles of the neck, and at the root of the tongue. His bowels were very costive. He was ordered one grain of calomel, and six of jalap, to be taken every three hours. On the following day he was better, but his bowels had not acted. The next day he had one or two copious motions, quite black, with a very foetid smell. In the evening he felt somewhat better, but the trismus remained. The treatment was continued, and the bowels began to act freely. The day following he could slightly open the mouth. The calomel and jalap were steadily persevered in. Day by day he got better under the treatment, and in a week or ten days the tetanic symptoms had quite left him. In another case, a man met with an accident, and smashed his hand, and the tendons were considerably lacerated. In a few days trismus occurred. The mouth was completely shut, and he had stiffness at the back of the neck, and at the root of the tongue. He was treated exactly as in the last case. The bowels were copiously relieved; the jaw relaxed, and, at length, the tetanic symptoms disappeared. In a case of compound dislocation of the ankle-joint trismus came on about the usual period. The patient was ordered calomel and jalap in the same proportions every three hours. In three days after the bowels had been copiously relieved the symptoms had begun to abate. In six days the mouth could be opened and shut naturally. I remember a case in which Mr. Abernethy was particularly interested. He saw the patient three or four times a day, and even witnessed the

administration of the medicine himself. The man had met with a lacerated wound of the foot. In a few days after the accident he was seized with trismus, and was threatened with the worst symptoms. It was a long time before the disease yielded, (six days) and opisthotonos had commenced. The same treatment as in the former cases was strictly pursued, but the bowels did not act for four days. They were at length copiously relieved. On the sixth day some movement of the jaw took place, and the patient from this time gradually recovered. During the period of four years eight patients under the care of Mr. Abernethy recovered from tetanus, being treated upon this principle. These cases show us the very great importance of administering purgatives, and clearing the alimentary canal in this disease. Without doing this first, any other remedies we employ have but little chance of having any effect in relieving the disease.

Nothing, perhaps, has tended more to promote the proper treatment of diseases than morbid anatomy, nor can we, I think, form any true criterion of their real nature, without having recourse to it. For this reason, therefore, I feel convinced that unless we at once go to the seat of the disease in tetanus, we have but little rational hope of relieving it. It is evident from the dissections that have been made after death of these cases, that the spinal chord and its membranes undergo a morbid change, and also the medulla oblongata, and sometimes the brain. We find on opening the spinal canal that it is usually filled between the arachnoid membrane and pia mater with fluid, and that there are depositions of lymph upon the former membrane, with apparent marks of inflammation on its surface. This can be traced, usually, along its whole course up to the medulla oblongata, where it joins the tuber annulare. The substance of the spinal chord itself, also, has an appearance of being redder than natural in most cases; but our knowledge of its structure both in health and disease is so limited, that it would be difficult positively to say that it was inflamed, although there is every appearance of it. It is only to be hoped, that, as our knowledge of microscopic observation increases, that we shall discover the more minute structure of these textures.

From the evidence I have brought forward it appears to me that our treatment of tetanus ought to be more especially directed to the spinal chord and its membranes. The arachnoid membrane and pia mater of the spine are as delicate membranes as the iris of the eye, and there appears to me to be a great analogy between them. The iris, when inflamed, deposits lymph upon its surface, and the arachnoid membrane does the same, secreting likewise a serous fluid.

In *iritis* it is of the greatest importance that the lymph should be immediately absorbed, or it would become organized and destroy vision. With the view of promoting the absorption of the lymph, we prescribe calomel and opium at stated intervals every four or six hours, and it is gradually taken away by the absorbents, and the iris is left free. The same principle of treatment might be adopted in tetanus. There is an effusion of serum between the arachnoid membrane and the pia mater, and lymph is deposited upon the former. Mercury, administered in the same manner as in *iritis*, might be the means of promoting the absorption of the fluid and lymph, and curing the disease. Mr. Abernethy considered that his treatment was "by gently exciting the bowels to action by repeated small doses of purgatives," and he appeared to have overlooked the effect of the mercury. If a grain of calomel be taken every three hours, and continued for four or five days, there can be but little doubt that it would enter into the system, and gradually cause absorption from the arachnoid membrane, in the same manner as it does in *iritis*. I am inclined, therefore, to think, that the good effect derived from Mr. Abernethy's treatment in tetanus was not only from the purgative, but from the mercury also bringing the absorbents into action, and thus not only removing the cause of the disease, but preventing at the same time its further progress.

I am aware there has been a very great prejudice in the minds of some practitioners against the use of mercury in this disease, but I suspect, when such has been the case, that it has been improperly employed; for when *ptyalism* is spoken of, it proves that it has been given to a greater extent than it ought to be. Mercury administered upon principle, and merely given as a remedy without principle, is very different in its action. In the one it is employed for a particular reason, while in the other no cause can be assigned; consequently, the employment of it fails. If mercury be taken in large doses, and rubbed in, it produces *ptyalism* too soon, and does harm; but if it be given in moderate doses, and at stated intervals, it acts equally, and, by so doing, gradually overcomes disease. The misemployment of it is too frequently the cause of its failure. The morbid appearances seen in tetanus certainly favour its exhibition on the same principle as in *iritis*.

But one of the principal symptoms of tetanus is, violent paroxysms of spasm, and to subdue these is of the greatest importance, for, in one of these, the patient usually dies. For this purpose many remedies have been employed; opium has been given to a great amount, and, certainly, with more benefit than any other remedy. In a table made by

Mr. Blizard Curling, of 128 cases, about 60 patients recovered. Out of these, 45, and more, took opium, combined with other remedies; others antispasmodics, such as aether: musk, conium, camphor, digitalis, hydrocyanic acid, &c., have been employed, but with so uncertain advantage that they cannot with certainty be relied on. There has of late been a new remedy introduced from India—the extract of Indian hemp, or *extractum canabis sativa*, which has been discovered to have a powerful effect in allaying spasm. Dr. O'Shaughnessy first introduced it into European India, finding it a powerful antispasmodic, and, more particularly, in tetanus. Mr. Lee, late of Crawford street, was, I believe, the first who tried its effects in this country; since which, my colleague and friend, Dr. Clendinning, has written a very able and interesting account of it in the Transactions of the Royal Medical and Chirurgical Society, (Vol. 8, second series), and its virtues. It appears that it has the same good effect as opium, without its unpleasant consequences, and when opium and its different preparations will not, the tincture of indian hemp does succeed.

The spasm in tetanus is sometimes so violent that it is necessary the patient should be held by three or four individuals. In such cases, and indeed I should recommend it in all others, I have employed the extract of belladonna rubbed along the whole course, and on each side of the spine, with the greatest advantage. The spasm, as soon as the belladonna acts, ceases, and does not return while the patient is kept under its influence—at least in the only three cases I employed it in it did not. In the one, the patient was seized with traumatic tetanus, and there was trismus and opisthotonos, accompanied with such severe spasm of the whole trunk and limbs that four persons could hardly hold the patient in bed. The extract of belladonna was rubbed along the whole course of the spine on each side, and in half an hour afterwards the spasm had entirely ceased; the patient could open the mouth, which before was firmly closed, so as to admit the fore-finger between the teeth, and the opisthotonos was greatly relieved. The belladonna was washed off, and fresh was reapplied every three or four hours, and for seventeen hours the patient was perfectly tranquil. It unfortunately happened, however, that, from the large quantity required to be used, the supply of it failed about two or three o'clock in the morning, and before any more could be procured, five or six hours having elapsed, the patient was seized with another paroxysm of convulsion, of which she died.

In the second case, which occurred more than twenty years ago, there was violent spasm of the trunk, with opisthotonos. As

soon as the belladonna was applied the spasm ceased, and the unfortunate patient died without pain. In a third case, (No. 4), which I have related in this paper, no paroxysm of spasm occurred, but the patient died of inflammation of the trachea and larynx and pharynx, as in hydrophobia. In speaking of this remedy, however, I only offer it as auxiliary to the other means recommended. It appears to me that if the spasms could be prevented or quieted, that it would give time for the treatment employed to produce the proper effect, and also might be the means of preventing the sudden death of the patient.

Venesection has been recommended in tetanus, and certainly in some cases it appears to have been attended by benefit. Bleeding, judiciously employed, in the first stages of the disease, I have but little doubt would tend to diminish the violence of the spasm; but in the latter stages it would rather assist than diminish the fatal termination. Amputation has been proposed, and in some instances adopted, but the success is very doubtful. A case or two have been recorded where it has appeared to succeed in gun-shot wounds, but in others no advantage whatever has been derived from it, as may be seen in Case II., which I have here related. In some cases, also, the nerves going from the injured part towards the spine have been divided, and with apparent good effect. If the injury causes tension of the nerves, this operation, by relieving irritation, might be beneficial; but usually the disease is too deep-rooted on the motor tract of the spinal chord to be affected by any local treatment.

Cold affusion has been thought highly of by some, but it has been chiefly used in hot climates, and the patients mostly have been negroes.

In concluding these observations, it is evident, to my mind, that tetanus is a permanent disease on the motor tract of the medulla oblongata and spinal chord, brought on from some distant reflected local irritation. The treatment of it, therefore, ought to be directed accordingly, and the following means are those which I think are the most advisable to be pursued:—

1st, If the patient be plethoric, one general bleeding from the arm might be had recourse to, according to the violence of the symptoms.

2d, Leeches might be applied along the whole course of the spine, and more particularly at those spots where the muscles were most spasmed.

3d, The extract of belladonna might be rubbed on each side of the spine, and more particularly at the spasmed portions, whereby the paroxysms might be prevented.

4th, Purgatives might be administered,

and the contents of the alimentary canal evacuated gradually, as recommended by Mr. Abernethy, by giving doses of calomel and jalap every three hours, and if that should be not active enough, one drop of croton-oil.

5th, When the bowels had been sufficiently relieved, then calomel and opium might be prescribed as for iritis, and persevered in until the mouth became sore.

6th, Should the disease become chronic, counter-irritants might be employed, such as blisters on each side of the spine.

7th, Should the paroxysms of spasm be very violent, Opium, the Tinct. Canabis Sativa, or the Extract of Belladonna, or any other antispasmodic, might be exhibited internally, according to the best judgment of the medical attendant.

8th, Soothing remedies might be employed to the wound, such as a strong solution of opium, hyoscyamus, poultices, &c.

9th, If there be tension of the nerves they might be divided. And

10th, Should there be a peculiar state of the wound, causing more than ordinary irritation, or should it be impossible to save the limb, then amputation might be performed.

The above principles of treatment appear to me to be the most rational methods that can be adopted for the relief of tetanus. It is not impossible that at some future period some discovery will be made to cure it, but until that happy time arrives it is our duty to pursue the most likely means of overcoming this most dreadful disease.

APPENDIX TO THE ESSAY

ON

DISEASES OF THE NERVOUS SYSTEM:

CONTAINING NOTES OF THE LECTURES OF
THE LATE PROFESSOR GREGORY,
OF EDINBURGH.

BY EDWARD BLACKMORE, M.D. Edinb.

Member Extraordinary of the Royal Medical
Society of Edinburgh, and Physician to
the Bath Penitentiary.

[Continued from page 925.]

On Insanity.

THE various disorders included by Cullen under the insane affections, are Oneirodynia, Amentia, Melancholia, and Mania.

1. Dreaming, frightful and oppressive, with groaning, from a sense of weight on the breast. People in dreams fancy they see or hear what is not to be seen or heard. It is not from an organic affection; it all comes in a

quarter of an hour, or in a minute. The function of the brain is irregular; there is no commanding of the imagination; the usual association and relations of ideas are lost; yet some persons have power over their thoughts in the disturbed sleep that attends dreaming. Dr. Reid, when young, used to dream frightful dreams; he resisted it, and got the better of it, having fixed it in his mind that he never had been in real danger. Once he dreamed he was on the brink of a precipice, made a bold effort to throw himself down, and awaked and did not dream again for forty years. On a blister being put on his head some years afterwards, he dreamed he had fallen into the hands of savages, who scalped him.

Dreams may often be referred to a cause, producing imperfect or disturbed sensation. We can trace them to external impressions, or to a state of the internal organs; this impression or sensation makes the beginning of a train of thought, which goes on. Once, on putting hot water to my feet, I thought in my dream I was ascending Etna, and that travellers who spoke of snow on the mountain were liars. Having been once on Vesuvius, where I felt the ground hot under my feet, the hot water brought to my recollection Mount Etna, Brydone's account of which I had been reading. Once also, from cold in the night, I thought I was in Hudson's Bay. The most common cause of this dreaming is the habitual use of strong liquors, or a heavy supper.

There is a wonderful rapidity of thought in dreaming: a dream of a number of particulars will be included in a minute. One thought he had enlisted for a soldier, deserted, and was taken, tried, and shot, while a door was opened and shut violently.

2. Idiotism, an inability to perceive the relations of things. All persons are idiots in early infancy; intellectual power is gradually acquired. A certain tone of the voice, in childhood, may indicate that one will never arrive at maturity of judgment. In the progress of life, also, we approach to amentia; some retain their faculties perfectly to the age of 90; others lose them before 60.

Idiotism is seen also in a loss of memory. Memory is the foundation of our judgments. In senility common occurrences are little attended to, and

are soon forgotten. "No old man," says Cicero, "ever forgot where he had laid his money!" The habit of mental inattention influences the memory; and so does the state of the brain. Loss of memory supervenes on fever, and it arises also from emotions of the mind, and excessive venery. A stupid fellow is said to have had a blow on his head, and to have become clever; another blow brought back his stupidity.

3. Melancholy, a fixed idea, an erroneous notion; as in the case of one thinking his affairs are going to ruin, and that he will be reduced to poverty. Some think they are eternally damned. Simon Browne thought his soul was taken from him, and that nothing but animal life was left him; he dedicated a book of great talent to the Queen, and begged her intercession with God. Some fancy they are turned into a horse, dog, or wolf. One thought he had no head; a box on the ear cured him. Others have a distortion of the mind, anxiety about their health; such have often the melancholy temperament, but not always. I have seen this sort of low spirits in the sanguine temperament; and it is not always connected with dyspepsia, although Cullen thought otherwise. Persons are insane on one topic, and rational on others. The monomaniac is not always melancholy; some are in high spirits, in imagined prosperity, while their affairs are going to ruin; or believing themselves "elect," and sure of salvation. Don Quixote was mad on one subject, that of knight-errantry; another is mad on the plan of guiding an air-balloon, or on politics, or on acquiring money. In all it is an erroneous notion, thinking something to be done or intended, without just reason for thinking so. Some shew a tendency to wander about; many have a disposition to suicide; if I hear of such, I say, "I am glad of it; it is better than murdering another."

4. In mania there is not the usual train of thought, nor a command of thought; it is styled mental derangement, disorder of the mental function. Some are bent on one particular thought; there is a look of horror in the countenance, a preternatural rapidity in the succession of sensations and perceptions. What is the train of thought it is difficult to understand; how it is produced we know not. A

sound state of the bodily organs is essential to a command of thought. It requires an effort to keep up muscular contraction, and also to fix the attention. A person in mania has violent keenness of thought, extraordinary muscular strength, and capacity of enduring fatigue and hunger and cold; and the insane will take an immense quantity of purgatives and opiates to affect them in the usual manner; one took twenty-eight grains of tartarized antimony with little effect on the stomach.

You must observe the least deviation from the natural state of the mental functions.

Mania is produced by moral causes, as emotions of the mind, grief, anger, fear, joy; many people were said to have come to Bedlam from the sudden acquisition of wealth, that is, from joy. In one family a daughter was found exclaiming, "My mother is wrong; I am the only one in my senses." She was raving, with a bell in her hand. The mother also was mad; the youngest daughter also died raving mad. The exciting cause was the acquisition of wealth; they had been in poverty, and on a fortune coming to them, all went mad. The mother languished, and died in a few months; the eldest daughter came to her senses, and married; her husband lost the fortune, but she retained her senses and composure of mind. Some women go mad on their approaching nuptials with men of their own choosing. Writers speak of religious madness, that is, madness from the excitement of religious controversies; others are mad from the love of projects.

The exciting causes are also—*a*, Strong liquors; and there is a modification of the insanity from the different kinds of liquors, as a vivacity from wine, cruel ferocity from distilled spirits, and heaviness from porter. The most ferocious drunkenness is said to arise from port wine mingled with brandy. *b*, Narcotics, as opium, stramonium, conium. Opium occasions in some persons disturbed dreamy sleep, and mental derangement rather than sleep. A lady, to whom I thought of giving an opiate, said it always disagreed with her. I gave it, and she became delirious for three days. I have found some become maniacal after the large use of mercury.

Mania is also connected with various bodily disorders, as—1. Obstructed menstrua, and the consequent determining of blood to the head, and increase of irritability. 2. The state of pregnancy. 3. The child-bed state. 4. The drying up of ulcers, and the suppression of habitual discharges. 5. Fever, the delirium of which is sometimes continued for a very long time. 6. Inanition, from want of diet, and from other causes of exhaustion.

There is a predisposition which is hereditary; madness is observed running in families for generations.

The disease is styled mental derangement; but there must be something wrong in the bodily organs. The intellectual functions are performed by the bodily organs, as much as the senses of hearing and seeing; of the connection of the latter with the organs we know something; of the former, nothing. Mania is always, however, a corporeal malady.

Various morbid states of the brain are often discovered; how these produce the disease we know not. Extravagant hypotheses have been put forth on the cause of mental derangement; such as the jargon of Boerhaave about black bile, which he got from the ancients: hence melancholy was thought to be cured by purges, to carry off this bile. The bile may become black, but what is so called is generally blood. The speculations of Dr. Cullen about extraordinary or unequal excitement and mobility of different parts of the nervous system, is as visionary as the theory of black bile. All we know is, that high excitement of the nervous system is connected with mania, and that it is useful to lessen this excitement. I have no conjecture on the state of the brain adequate to make a person insane on one topic, and rational on all others. It is in some cases connected with inflammation, or irregular determination of blood to the head; and in others with a different state, a state of inanition, and a peculiar state of the nervous system, not dependent on the vascular state.

The Treatment.—Bleeding will sometimes remove maniacal symptoms.

Purges are the most ancient and the best practice; they lessen the flow of blood to the head. Some physicians think more good is done by mild purges, as tartrate of potass; the stronger also,

as calomel and jalap, are good. When large doses are inoperative, an opiate has made a small quantity effectual.

As habitual full living has led to mania, you give in such cases a cool spare diet.

I have found the disease attended with signs of inflammatory action; and the blood drawn in recent cases is buffy: this is a strong argument for low diet and evacuations, which do good almost universally in sanguine temperaments. In some cases bleeding *ad animi deliquium* may be tried, and you may open the temporal artery; or moderate bleedings from the arm may be better. Remember, that by this treatment you may also produce permanent imbecility instead of the mania which shall have passed away. In some states of the disease a cool spare diet is absurd; you must attend to the accompanying state of the constitution, and to the exciting causes of the malady, in order to determine the treatment.

Shaving the head is often good; you can then apply cold to it by wet cloths, or the clay cap, or a bladder with snow or ice in it, which is excellent, and generally better than a blister. The pediluvium, or a warm bath, while cold is applied to the head, may be of service; but the stimulus of a great degree of heat would be hurtful. Plunging into cold water, or the sea, and keeping the patient as long as possible under the water, without danger to life, is recommended by Boerhaave. There are striking instances of maniacs bearing cold, and showing the effect of great cold in curing mania; one wandered in the night in Russia, when the cold was at 69° under the freezing point, and was cured.

I object to emetics. I know not on what principle vomiting has been recommended; experienced people rather condemn it.

Blistering the head or neck may be good; sometimes it has done harm; and blisters to the legs, on the principle of revulsion, is foolish.

The strait waistcoat is necessary. You must restrain the patient from doing violence. In many cases more good is done by restraint than by all the medical treatment. It is injurious to tie them down with cords; they have torn their own flesh, and broken their bones. In Italy they secure the hands

to the sides; it is strong coercion, and will counteract the ferocity of the patients. Never allow them to wander about; confine them in a state of safety; let them walk in a garden with a high wall. To keep the patient in his own house is the worst thing of all; he must not have people about him whom he has been accustomed to see, and over whom he has had authority; he must be placed in the hands of strangers. You must get a seclusion, a retreat for them; one was always mad in a concourse of people, and in his senses while in his workshop; another was sane while in an asylum, yet retained as incurable, because on going home he became turbulent; a third would show irritation when visited at the asylum, and by keeping him quiet he was cured; another, who had been furiously maniacal, recovered from the change of scene and varied occupation of mind in a long journey.

Severity, as scourging and blows, must never be used; that would increase the ferocity. You must give a new turn to their thoughts, and assist them to recover the natural command of thought. Maniacs are capable of exerting command over their thoughts: observe their cunning; this is *ipso facto* a command over their thoughts. They will suppress all appearance of their derangement, and on getting their liberty they will relapse.

Some have been cured by constant labour. One used to cure his patients by employing them as his farm cattle; he put them in harness, and made them plough. He used to walk out with a new patient, pick a quarrel with him, and beat him unmercifully; then he said he was successful. Never be cruel or harsh; only use restraint.

Opium is given; it relieves the high irritation and want of sleep. One patient, when maniacal, took two hundred drops of laudanum; slept, awoke, and continued well. You may try a full dose, and repeat it until the effect is obtained. In some cases it has done harm. Valerian is insignificant. Camphor I have no faith in; I have never known satisfactory evidence of its being of service.

We have very imperfect testimony of the good or bad effects of a variety of treatment in this disease. In recent cases an active treatment is more necessary; and in long cases we should

not despair. Endeavour to change the train of thought by regimen and moral management. More good, in such cases, is done by attending to the state of the mind, than by the most powerful physical remedies; but you should employ both methods.

The hope of recovery is generally unfavourable; there is a strong tendency to a renewal of the disease. The morbid action, the essential part of the malady, comes in paroxysms; and although there are lucid intervals, it is often connected with some organic affection of the brain. The older the patient the less is the prospect of recovery; of the young, two-thirds have been cured; of those between 50 and 60, one-sixth only.

CLINICAL OBSERVATIONS ON SURGERY.

By R. H. MEADE, Bradford, Yorkshire.

(For the *London Medical Gazette*.)

I.—*Cases of severe injury, accompanied with very slight constitutional disturbance.*

It has often been observed, that when persons meet with very complicated injuries, they frequently recover with surprising rapidity, and suffer from less constitutional and febrile irritation than commonly occur after more simple accidents. It seems that in very extensive injuries, where several distinct parts of the body are hurt at the same time (when the shock is not so great as to destroy life before reaction takes place, and in which no internal and vital organs are seriously injured), the injury in one part acts as a check upon that in another, producing a sort of counter-irritation, which keeps down violent inflammatory action, and sympathetic fever. Whether there is any truth in this idea, or the effects have been merely accidental, I will not pretend to decide, but will relate one or two cases that have occurred in my own practice in illustration of the point.

In the evening of the 1st of November, 1843, I was sent for to see a strong robust man, named William Priestly, aged 42, who had met with a severe accident while sinking the shaft of a coal-pit. He was engaged with another man in blasting some hard rock with gunpowder, when the charge

accidentally exploded before he had time to avoid its effects. His companion escaped almost unhurt, being merely a little burnt about the face, but I found the poor fellow himself in the following state:—Both hands were completely shattered; the fractured extremities of the radius and ulna were exposed on one limb, and only remained attached to a few blackened fragments of the wrist and hand; while the mutilation of the opposite limb was not much less. The integuments of both arms, as high as the elbow, were much lacerated and burned; the skin, and in many places the cellular tissue beneath it, being infiltrated with dirt, fragments of stone, and gunpowder. The head and face were much injured. The features were so blackened and cut that it was difficult to recognise them. Sight appeared, at first, to be totally destroyed, the sclerotics and cornea of both eyes, as well as the lids, being extensively lacerated with fragments of stone, and blackened with gunpowder. On separating the lids the man could see light with the left eye, but the sight of the right was quite gone. Vision was probably destroyed at once by concussion of the retina, as the globe of the eye was not apparently penetrated by any of the wounds on its surface. There were several wounds in the scalp, and one deep cut on the front of the left leg.

As soon as he had rallied from the immediate shock of the accident, which was about three hours from the time that I first saw him, I amputated both arms below the elbow by the circular operation, leaving the stumps as long, and saving as much of the skin, as the injured state of the soft parts would allow. I then cleansed the lacerated and burnt integuments, and brought them together, so as to make two very good stumps. I put two or three sutures in each, and dressed them with spermaceti cerate. The burnt state of the skin precluded the use of adhesive plaster. He was now put to bed; his face and eyes were washed, so as to remove as many fragments of dirt and stone as possible, and a soft thin bread and water poultice (confined in a bag) was applied over the whole face. His other wounds were dressed, and I ordered him an aperient mixture to take every few hours.

He recovered without a symptom of

constitutional disturbance. The stumps united with rapidity; one was quite well in a fortnight, and both arms were completely healed in three weeks.

His chief sufferings arose from the injury to the eyes; considerable inflammation occurred in both of them, affecting all the external proper tunics, and being very protracted in its course. In the right eye, matter formed in the interior chamber, and between the layers of the cornea, and complete disorganization of the globe took place. In the left, very considerable inflammation of the cornea and sclerótica occurred, extending to the iris, which required for its removal the repeated local abstraction of blood, and the long-continued administration of mercury, so as to keep up a slight affection of the mouth. He ultimately recovered the sight of this eye, though it still remains very imperfect in consequence of opacity of the cornea, owing, in a great measure, to the presence of particles of gunpowder which are imbedded in its substance.

CASE II.—I met with a very similar case to the last during the preceding year. On the 1st of October, 1842, I was called to a man named John Wilson, who had been injured in precisely the same manner while sinking a coal-pit. He was a strong healthy man, about 45 years of age. His left arm and hand were so shattered that amputation of the limb was obliged to be performed a little below the elbow. The thumb of the opposite hand had also to be removed at its articulation with the metacarpal bone, in consequence of its having sustained a compound fracture with dislocation. One eye was destroyed, there being a penetrating wound of the globe; the scalp and face were extensively lacerated, and there was also a severe compound fracture of the left leg a little below the knee.

This man recovered without any febrile disturbance, or disorder of the general health. The stump rapidly healed, and the wounds on the head and leg soon closed. His chief sufferings (as in the former case) arose from the injured eye. Chronic inflammation of all the tunics occurred, which terminated in suppuration and collapse of the globe. His complete recovery was also retarded for some time by want of union between the bones of the

fractured limb. The external wound soon healed, so that it became a simple fracture; but it was necessary to continue the use of splints for nearly three months before union became firm. It seemed a consequence of the complicated injuries under which the man was suffering, that there was not sufficient vigour in the constitution to effect union between the fractured bones.

II.—*Case of recovery from a severe injury to the head, with suspected fracture of the base of the skull.*

William Wilson, about 35 years of age, a workman at the Low Moor Iron Works, was knocked down, on the morning of the 24th of May, 1844, by a violent blow from a heavy piece of iron, connected with some machinery, which swung round, and struck him on the right temple. I saw him about an hour after the occurrence, and found him labouring under severe symptoms of concussion of the brain. He was nearly comatose, being insensible to anything that was said to him, but very restless, and capable of articulating a few incoherent words. He was cold and pale, and had a very small, but a slow pulse. He had vomited several times, both on the road, and after he got home, and continued to do so while I remained with him. The contents of his stomach consisted almost entirely of blood, in a pure and partly coagulated state. Suspecting, from the appearance of the blood, that it must have been swallowed, and finding that the man had received no injury on any other part but the head, I examined the fauces, and found that the blood was trickling down the back of the pharynx, and evidently proceeded from the rupture of some vessel at the base of the skull, and passed down the œsophagus into the stomach. On examination of the head, the only external injury that could be found was a small contused wound on the right temple, a little above the upper edge of the zygoma, from which some blood was oozing. On introducing a probe, it passed through the temporal muscle, and I could feel the bone rough and denuded of its periosteum beneath, but I could not satisfy myself whether there was any fissure or crack; and the wound was not sufficiently large to admit of the introduction of the finger.

Diagnosis.—Judging from the symp-

toms which I have detailed, I suspected that there must be a fracture extending from the temporal fossa downwards to the base of the skull, and I accounted for the hæmorrhage by supposing that there was laceration of some of the vessels or sinuses at the base of the brain; for the blood to find its way into the pharynx must either have escaped from some vessels external to the skull, or have found its way through a fissure in the bone. The bleeding appeared to be analogous in character to that which is so commonly observed from the ears in cases of fracture of the base of the skull.*

My *prognosis* was of course very unfavourable, as I expected effusion of blood would probably take place within the cranium, as well as externally, and produce pressure on the brain; complete coma and death.

Treatment.—The man being in a state of collapse I did not venture to bleed him, though a modern writer, of no mean pretensions,† encourages the practice of taking away blood (in some instances) from the arm, “at the earliest period possible” after concussion of the brain, without reference to the state of the pulse. I ordered him to be kept as quiet as possible in bed, warmth to be applied to the extremities, a little warm gruel to be given him at intervals, if he could swallow it, and a bread and water poultice to be applied over the bruise on the temple. I also prescribed (chiefly as a placebo) an aperient mixture containing a little sulphate of magnesia, which was to be given him every hour.

In the evening I sent my assistant to see him, with directions to bleed him if reaction had taken place. He found him lying in a state of nearly complete coma; the vomiting had ceased, and also the bleeding in the throat. His skin was warm, and his pulse had risen considerably both in frequency and fulness. Under these circumstances he took about ʒiij. of blood from his arm, and directed the friends to continue the aperient mixture (some of which he had swallowed) during the

night. On the following day I found him much the same, still insensible, but breathing naturally, and with a full pulse. I repeated the bleeding from the arm, and ordered some leeches, and afterwards an evaporating lotion to be applied to the temple, which was now considerably swollen and inflamed. He slowly recovered, and as his consciousness returned (which was nearly a week first) he complained of considerable pain at the side and back of the neck, and back of the head, with stiffness in moving his jaws, and difficulty of articulation, which continued more or less for several weeks. He was six or seven weeks before he was able to leave his bed, and for many weeks after he was obliged to live very low, keep very quiet, and take purgative medicines, or he suffered from severe attacks of pain in the head, and sickness, which several times required the application of leeches for their removal. He ultimately got quite well, and continues so at the present time.

III.—*Case of severe sprain of the sacro-iliac articulation.*

The following case possesses no other feature of interest besides its rarity. The sacro-iliac articulation is so strong that it is very seldom injured except in severe cases in which the pelvis is seriously damaged, and in which the injury to this joint is complicated with fracture of the bones and other mischief.

William Clayton, aged 25, a strong young man, by trade a mechanic, while working in a mill for the construction of machinery, met with the following accident in the beginning of April 1844. A rack suspended from the roof or ceiling of the building in which he was working, and which was filled with a number of heavy bars of iron, gave way, and fell upon him. He was standing in a corner of the room, and was in a stooping position at the time, so that he received the weight, amounting to more than a ton, on the back of his head and shoulders, and was forcibly bent down into the corner with his legs doubled under him. When extricated, it was found that his head and back were unhurt, but he complained of the most excruciating pain in the right hip, and at the lower part of the back, which was increased by any attempt to move

* We cannot agree with our correspondent in thinking that the presence of blood in the pharynx was sufficient evidence of the existence of a fracture through the base of the skull. It might, as he admits, have escaped from some vessels external to the skull.—*Ed. GAZ.*

† A System of Practical Surgery, by Professor Ferguson. pp. 427.

the right leg, or to bear any weight upon it. I saw him about two hours after the accident, and found him complaining of constant and dreadful agony, which he described as having the aching character peculiar to a severe sprain. On examining the part affected he referred the pain exactly to the point of junction of the sacrum with the right ilium. There was no bruise or sign of external injury over the part, except some swelling, and, in fact, he said that he had not been struck in that situation, but felt as if the injury had been caused by the weight which fell upon him forcibly doubling him up, and straining the lower part of his back. I could detect no injury to the bones of the pelvis or thigh, nor to the hip-joint, and the man could move the affected limb, though it caused him an increase of pain to do so. There was great tenderness, and, as I have mentioned, some swelling over the sacro-iliac articulation. The pain continued for several days, of the same constant aching character, but was unaccompanied by any constitutional disturbance. It gradually subsided, though for several weeks he could not bear to press the foot on the ground, and it was six or seven weeks before he attempted to walk. He ultimately quite recovered, and returned to work about two months after the accident: he was then still rather lame. The treatment consisted of perfect rest, with the application of leeches and fomentations in the first instance, subsequently gentle friction with soap liniment, and ultimately the application of a soap plaster spread on thick leather, supported by a bandage.

THE PERIODICAL MATURATION AND EXTRUSION OF OVA, INDEPENDENTLY OF COITUS, IN MAMMALIA AND MAN,

PROVED TO BE

THE
PRIMARY CONDITION TO THEIR
PROPAGATION.

By TH. L. W. BISCHOFF,
Professor of Medicine, and Director of the Physiological Institute at Giessen, &c. &c.

Translated by

HENRY SMITH, Esq. F.R.C.S. &c.

(Concluded from p. 699*.)

I THINK that the following observations upon a rat may also be classed with the

foregoing. The animal was taken in a trap during the night between the 1st and 2d of February, 1844, and remained in it alive until 11 A.M. on the morning of the third. On examination after death, which was effected by drowning, it appeared that numerous large and recent corpora lutea were developed in the ovaries. Inferring from that circumstance that the animal had been impregnated only a short time previously, I examined the vagina, uterus, and fallopian tubes, most minutely, but could not find any trace of seminal fluid in either of them. I discovered, however, the extruded ova in the commencement of the tube. I may observe, that the ova are extremely difficult to find in the oviduct, both in this animal and in the mouse. The tube is so small that it is not possible to cut it open with even the finest scissors. The observer therefore has no other resource left him but to dissect out, in the first place, all its tortuosities carefully, which of itself is no easy task, they being very closely compacted, and the tube measuring scarcely half a Paris line in diameter, and then to remove the contents of the oviduct, by very cautious and gentle scraping of small portions at a time, on to a plate of glass, examining them afterwards most minutely with a simple microscope. It is very difficult to detect the ova even then, for they are not only very small, but almost perfectly transparent also, the yolk being composed of only a very pale minutely granular substance. I was, however, as I have stated, fortunate enough to find the ova in the superior third of the tube. They measured, including the zona, 0.0041 P. in. = $\frac{1}{27}$ P. line, = $\frac{1}{3}$ millim. in diameter. The zona was about 0.0002 P. in. = $\frac{1}{300}$ P. line, = $\frac{1}{140}$ mil. in thickness. There was no longer any trace of the cells of the discus around the zona. The vitelline mass completely filled out the interior of the zona in all the ova; and I could not discover any thing of a vesicle, corpuscle, or the like, in them. I should attach great importance to the latter circumstance if the observation itself

the last part of this paper, during its passage through the press, although I had observed it in my manuscript. It occurs at page 696 in the second column, and line 18 from the bottom. The sentence should read thus, "receded from it, as though indicative of the presence of the germinal vesicle."

* I find I omitted to correct a serious error in 90s.—xxxv.

did not admit of a doubt with regard to its correctness; for the fact of the yolk being so very transparent ought to render the observation of those changes which occur in the germinal vesicle or germinal spot, previous to the commencement of the division of the yolk, much more easy in this than in any other mammalian ovum as yet investigated. The contents of the oviduct are, however, so small, that the ova cannot be examined at all without the addition of some fluid; and it becomes a question as to what changes that (in this instance it was saliva) might have already induced in the interior of the delicate ovulum. An ovarian ovum which I examined had about the same diameter; the yolk was, however, still more pale, and I most distinctly recognised in it the germinal vesicle, measuring 0.0011 P. in. = $\frac{1}{70}$ P. line, = $\frac{1}{31}$ millim., with its germinal spot of about 0.00039 P. in. = $\frac{1}{210}$ P. line, = $\frac{1}{93}$ millim. The germinal spot refracted the light strongly, had a very dark outline, and resembled a fat globule.

I think that this rat had not been impregnated, but that the ova had quitted the ovary and entered the fallopian tube notwithstanding. Had copulation been effected, according to all that I have observed on this point in other animals, the spermatozoa would have been discoverable somewhere in the female organs of generation, for the ova were yet in the superior part of the oviduct. In a mouse, in which, about two years previously, I had found the ova near the same spot in the oviduct, the entire uterus and the tubes were distended with seminal fluid, and spermatozoa were also present upon the zones of the ova. Probably, therefore, this rat was made a prisoner in the commencement of "the heat," before copulating, and the ova had quitted the Graafian vesicles without impregnation.

Previous observers, and among them Barry (Researches in Embryology, 2d series, p. 319, § 161), have frequently observed Graafian vesicles in the ovaries of the rabbit considerably swollen, and filled with blood. Several instances of the kind have presented themselves to me, but always only in does which had remained for a long time separated from the male. I never found an ovum in them, but only blood-corpuscles, the figure of which was more

or less distinct, definitely preserved, and recognisable. I think it probable that they are Graafian vesicles of a former period of "heat," from which the ova have escaped without the act of copulation having taken place. A short time since I examined a rabbit six or eight hours after coitus, and found that the ova had not as yet quitted the Graafian vesicles, which were much swollen. In addition to these, however, there were corpora lutea of a considerable size in both ovaries, which could not be the effect of a previous littering, as they were much too large for that, and the animal had also been kept alone for several weeks previously. I regard these, therefore, likewise as corpora lutea of a "period of heat" which had passed over without copulation.

From all that I have stated, then, it is quite certain, that at the period of "heat," and even when no act of copulation takes place, the ova of mammalia are extruded from the ovary, and enter the fallopian tube, but that they there prove abortive: corpora lutea, however, are formed upon the ovary as though coitus and impregnation had been effected.

As a counterpart to these observations, which prove the maturation and extrusion of ova independently of the seminal fluid of the male, I will adduce another fact, which proves the same on the other hand for the semen.

On the 6th of March, 1844, I examined a bitch, not knowing when the animal had received the male for the first time, but being certain that coitus had taken place the day before. The left ovary exhibited three corpora lutea, and in the centre of the oviduct I found the three ova quite normal in condition. The right ovary, on the contrary, was very small, and did not exhibit either a swollen or an opened Graafian vesicle, or corpora lutea, and of course there was no ovum in the tube. I found spermatozoa, however, in the uterus and oviduct not only as high as the ovary, but upon it. This proves positively that no especial design is in operation here. According to the general mode of considering organic phenomena, which always presupposes a precise design, one would have supposed that when no ovum was to be fecundated the seminal fluid would not have reached the part. But it had pursued its customary course uninter-

ruptedly, just as the ovum takes its own quite independently of the semen. There is no attraction, no polarity, or such like force, in operation here, such as we are so ready to apply to the supposed explanation of certain natural phenomena. Ovum and seminal fluid are altogether independent products of older organisms. Their meeting, and the consequent fecundation of the ovum, although necessary for the maintenance of the species, are in themselves quite accidental occurrences, frequent instances of which are so clearly evident in organic nature.

If, then, the foregoing observations prove, with respect to mammalia, that their generation and propagation are brought about *primo loco* by the spontaneous periodical formation and maturation of ova, and not by copulation, analogy alone would lead us to presuppose the like for man. But even here indirect proofs at least are not wanting.

It is well known that the function of menstruation in the human female was long ago and frequently compared with "the heat" in animals. Some of the most intelligent physicians and naturalists of various periods have adopted this opinion, although it was contended against by others no less celebrated than themselves. Regarding Bardach as the most important of the latter class, the only argument of all those brought forward by him which seems to me to have any weight is that in which he draws attention to the important distinction existing between "the heat" and menstruation, in respect to sexual impulse and copulation. The beast copulates *only* during "the heat;" man, on the contrary, always feels himself repelled from the female during menstruation. If this were correct, I should also be of the opinion that it involved an essential distinction. But attentive observers have previously remarked, and I can only confirm it, that such a distinction is altogether wanting, for the female of animals also manifests, at the commencement of "the heat," a condition of sickness, during which it altogether refuses to permit coitus to be effected. It seeks that act for the first time only when the phenomena attendant upon "the heat" have reached a certain stage of development. It is, however, also well known that a sensation of unusual

good health comes on, and the sexual impulse especially manifests itself in the human female, on the passing off of menstruation, and it seems to me, therefore, that the most complete accordance occurs here, and that all the arguments which have been brought forward in favour of the analogy between "the heat" and menstruation are rather strengthened than otherwise. A repetition of the arguments here would be superfluous.

All intelligent anatomists, physiologists, and physicians, have long since been convinced that the cause of menstruation, as well as that of the sexual impulse, and of the whole female character, is to be sought for in the ovaries. But that the uterus, on the other hand,—although it be the organ in which the characteristics of classes and species are most especially manifested, in so far as regards the genital organs,—yet, in the above respect has but a secondary importance. Numerous pathological facts of the most diverse description, and primary deviations from the natural formation, exhibit most constant accordance with this view. I shall quote only one such instance here; it is from a recent and almost unknown source of information upon castrated females, communicated by Dr. Roberts, in a work descriptive of a journey from Delhi to Bombay. The persons examined by him were twenty-five years of age, large, muscular, and perfectly healthy. They had no breasts, no nipples, and no hair on the pubes. The vagina was completely closed, and the arch of the pubis so narrow that the ascending ramus of the ischium, and the descending ramus of the pubes, were almost in contact. There was no deposition of fat about the neighbourhood of the genital organs, nor were the nates more developed than in man, whilst the rest of the body was well provided with fat. There was not a trace of menstrual secretion, nor anything which might supply its place; there was also no sexual impulse.

Anatomy has also recently furnished direct proofs in favour of the views advanced in this essay. Surprising as it seemed at first, from the endless controversies carried on respecting the corpora lutea, there is now no longer any doubt of the fact that, at each return of the function of menstruation, the ovary takes on a condition of in-

creased activity, that a Graafian vesicle becomes considerably developed, and bursts, and that a corpus luteum is formed in its place. The researches of R. Lee, Paterson, William Jones, Negrier, Gendrin, Raciborsky, and Pouchet, leave no room for doubt on this point. It would occupy too much space to repeat their observations here: I will only mention, that I have myself had the opportunity of making four observations which bear upon this part of our subject, all occurring in young and healthy persons, three of whom met their deaths by drowning, and the fourth died very suddenly. I found indubitable appearances of menstruation in all of them; on the ovaries of three of them a Graafian vesicle which had burst and was filled with blood, and on the fourth an enormously swollen one which had a diameter of seven lines. I learnt afterwards quite decidedly with respect to one of these instances, that menstruation was going on at the time when she met her death.

I have just received intelligence from Dr. Ecker, of Heidelberg, that he had found a Graafian vesicle which had burst, and was filled with a recent coagulum, in the body of a person aged 25, who had lately been executed there, and in whom menstruation had been present twelve days before death. He examined the tube with great care in search of an ovum, but in vain, probably because it had by that time undergone dissolution. Besides, in my opinion, the human ovum may be classed amongst the most difficult of all tubal ova to discover, in consequence of the slight density of its yolk, and the vaguely defined outlines of its zona.

It is therefore not to be wondered at, that numerous earlier observers—Valisneri, Santorini, Roederer, Haighton, Home, Brugnioni, Cruikshank, Meckel, Blundell, and others—have seen corpora lutea upon the ovaries of those who had never been pregnant, and even in those of virgins and young girls. Such instances were always regarded as exceptions to the rule, as pathological, or as results of sexual excitement occurring at some former period without coitus, whilst they no doubt were produced by recent menstruation, or the opening of a follicle and escape of an ovum.

Lastly, it is a well-known fact, that women conceive the most readily im-

mediately after menstruating, and even examples are not wanting where this took place only during menstruation.

It is likewise now a settled point that there is no more certain mode of reckoning the period of pregnancy, than that which dates from the last occurrence of menstruation. I have been informed by Professor Nägele that he had never once been deceived when reckoning nine months and eight days from the last menstrual period in regular instances. At the same time he told me, that he had frequently removed sterility by advising coitus immediately after, or even during menstruation.

Although at the present moment direct information as to the fate of the ovum during and after the menstrual period may be wanting, (for supplying which I hope that an early opportunity, combined with the necessary dexterity and care, may be presented), yet no doubt can be entertained, that:

“In the human female, during the period in which she is capable of child-bearing, there occur every four weeks a maturation and extrusion of an ovum from the ovary, which process is accompanied by a simultaneous secretion of blood from the uterus.”

I have no doubt that this law will not only stand the test of future experience, but will also serve to explain many phenomena hitherto unintelligible*. Experience will teach us what are the limits of its application in man. It appears that the secretion of blood from the uterus commences whilst the ovum is still inclosed by its Graafian vesicle, and that the latter bursts and the ovum escapes towards the termination of that function. While in the tube, the ovum is probably for some

* Dr. Panck, of Dorpat, lately brought forward a case, in which he considered he had discovered a remarkable organic connection between the fallopian tube and ovary soon after conception, by means of which the passage of the ovum from the ovary into the tube is effected and secured. For my part I am convinced, and for the following reasons, that this was a case of commencing menstruation, but not one of conception; firstly, coitus was by no means proved to have taken place; secondly, Professor Bidder did not find any spermatozoa in the genital organs, and lastly, because, although the conjectural act of coition should have been effected five days previously, yet the Graafian vesicle was still closed. I consider the connection between the ovary and fallopian tube, which was observed in this instance, as decidedly pathological. Delicate false membranes, of precisely the character described, are very common in connection with the female organs of generation.

days capable of fecundation on copulation being effected. What is the limit to this capacity? Direct observations alone can answer this question, and they are as yet altogether wanting. I believe, however, that I have a right to assume that fecundation must take place while the ovum is in the fallopian tube, since it is extremely probable that development first commences there. If, from all the information we at present possess, the conclusion may be permitted, that the ovum of the rabbit remains three days, that of the ruminant from four to five, and that of the dog from eight to ten days in the oviduct, we might then assume the ovum of the human female to be capable of fecundation during a period of from eight to twelve days after its extrusion from the ovary; thus probably, also, from eight to twelve days after the cessation of menstruation. Such a conclusion, however, being based upon analogy, is hazardous, for we know that very great varieties exist in different animals with respect to the time during which the ovum remains in the oviduct; for example, in the deer, according to my own observations and those of Dr. Zeigler, it most probably requires even months for its passage through the tube. All the attempts to define this period which have hitherto been promulgated,—where ova 12, 14, and 21 days old are reported to have been seen in the uterus, and in which even the embryo was already far advanced in its development,—are altogether unworthy of confidence, since they date from the act of coitus, which only specifies the limit of impregnation, but not the period at which the ova quit the ovary, nor do they admit of any conclusion as to the latter being drawn from them. The lengthened period during which the human ovum is capable of fecundation may possibly have been the cause why observation has as yet proved nothing precise upon this point. On the other hand, it does not appear that any ordinary circumstances, such as physical and moral excitement of the sexual impulse, and the like, could easily induce a change in the character of the maturation of ova, and thus also in the possibility of impregnation. The fact is contradicted by all our experience with regard to menstruation, which proves, indeed, that that function can be, and actually

is, sometimes accelerated or retarded; but still only by the operation of causes which exert a far deeper influence than those alluded to. Of course, all that is known with respect to menstruation has its value in relation to this point, since it indicates the period of maturation of an ovum; but the collected evidence with regard to that function shews an alteration, such as that mentioned above, to be something uncommon; and all our latest information on the formation of corpora lutea proves only that the above-named influences can hardly possess such a power.

It is doubtless unnecessary to draw attention to the extraordinary importance attached to the discovery of a law which relates to one of the weightiest interests of mankind. Science and society in general are in the highest degree interested in it. On this account I most warmly desire that numerous further tests of its truth may not be wanting, and that it may not be opposed by antiquated deeply-rooted prejudices, which are sometimes regarded as experience. But whoever proceeds to the test should previously qualify himself for the task by much embryological research, for he has to do with things which are not easily ascertained. The errors of centuries, not indifferent about the question, prove this. I hope to be able to meet well-grounded doubts, and will at once proceed to remove one such, which has already been frequently opposed to me. I have often been asked, "If conception be dependent on menstruation, and this again on the maturation of an ovum, how does it occur that women have frequently conceived who had never menstruated?" My reply is the simple statement, that although the secretion of blood be a normal, and the most striking phenomenon which accompanies the maturation of an ovum, yet it is by no means indissolubly connected with it. This is proved by the first glance at the animal kingdom, where this periodical maturation of the ova often occurs with, but more frequently without such a secretion. In the human female it is altogether a normal and important phenomenon; but by no means one which is essential,—it is only accidental. It may be absent, but mature ova may nevertheless be developed, and therefore also become impregnated. This will readily

harmonize with what experience shews, that in general such women are also altogether free from any abnormal symptoms.

Again, many will no doubt question the law laid down, on the ground that it is scarcely conceivable that so important a circumstance should have escaped observation altogether, and especially that of anatomists and physicians, during their numerous disputes respecting the corpora lutea. To this I would reply, that it is quite true many striking points were long since known; as, for example, the dependence of fruitfulness in the female upon menstruation, the admission of the fact that conception takes place more readily immediately after menstruation, the reckoning of pregnancy according to the last appearance of that function, and the like. The reason why these observations did not lead to the full knowledge of the matter lies no doubt in the frequent recurrence of the menstrual period, or the maturation of an ovum, and possibility of a conception. If women menstruated only once or twice in a year, it would long since have been remarked that such was the only time when conception was possible; menstruation would long ago have been recognised as perfectly analogous to "the heat" in animals, even though the most essential element of it, namely, the maturation of ova, had not been discovered. The possibility of conception, however, is, on the one hand, so frequently repeated, in consequence of the menstrual period occurring every four weeks, that, in the absence of farther data, it was not easily possible to fix the point of time with which it was connected more accurately; and, on the other hand, menstruation passes over so frequently without its purpose, conception, being attained, that the attention must naturally have been directed more to that function than to the dependence of conception upon it. With regard to animals, it was the precisely opposite relation of circumstances which proved the impediment to the correct perception of the analogy between "the heat" and menstruation. In them the period of heat either occurs so seldom, once or twice a year, or, when repeated more frequently, as in the cow, the sheep, the pig, &c. it is so interfered with by ordinary circumstances, such as our eco-

nomical arrangements and the like, that the animals are either immediately impregnated, or that the recurrence of the maturation of ova is obstructed and stopped by the secretion of milk. That an analogy, otherwise so striking, with one of our commonest domestic animals, the cow, should have remained for the most part unnoticed, is no doubt to be attributed to some of the above circumstances.

As regards the researches of anatomists and physiologists, we may remark, that they in the first place did actually make some correct observations; such, for instance, as those proving the formation of corpora lutea without coitus and conception. The fact that they did not interpret them correctly, nor develop them further, is an additional proof of the necessity for not only the corporeal eye and hand, but in the intellectual eye also for our observations, and shows how necessarily our researches must be accompanied by an idea, by reflection, if they are to apprehend correctly even simple relations of things. But these ideas were not mature, they could not be so; and the eyes of men, otherwise most distinguished, could not therefore be enlightened by them. Lastly, however, the rare opportunity for making observations on this subject must certainly be allowed great weight. Such opportunities occur but very seldom after the usual mode of death, the result of disease. Menstruation, the maturation and extrusion of ova, is too intimately connected with the functions of health, not to be interrupted by almost all modes of death, and therefore it is that, on examination afterwards, nothing is found. It is only in the bodies of perfectly healthy persons, who have met a violent death, that we can hope to obtain the required circumstances for observation. And how many of such as die suddenly will meet with their deaths exactly at the period of menstruation? and again, how many of those who do, will fall into the hands of such as are competent to so minute an investigation? The most favourable opportunities for the purpose would be afforded in the cases of executed criminals, where the requisite facts with regard to dates and so on may be precisely fixed.

[The remaining portion of the essay is chiefly devoted by Professor Bischoff

to the establishment of his claims to priority in the discovery of the fact which it is written to establish. His great rivals are Raciborsky and Pouchet. Having omitted that portion, under the impression that it would not be generally interesting, I feel myself bound to state that Professor Bischoff has so clearly and so fairly laid before his readers the facts of the case, that I think no one can have the slightest doubt of the merit being solely due to him. Others, as he says, may have given *indirect* proofs, but he has furnished the *direct* ones. I beg, in concluding my task, to apologize to the readers of this journal for the rough, and sometimes almost literal style in which I have placed my friend's valuable essay before them; I can only plead as an excuse, that my great object was to be faithful to my original, and that, had not the various divisions of the essay been prepared by me in great haste, and during a period of peculiar anxiety, I should gladly have devoted more time and labour to my subject.—
TRANSLATOR.]

ANALYSES AND NOTICES OF BOOKS.

“L'auteur se tue à allonger ce que le lecteur se tue à abréger.”—D'ALEMBERT.

The Veterinary Record, and Transactions of the Veterinary Medical Association, April 1845.

WE have derived much satisfaction from looking through this number of “The Veterinary Record”—a new publication devoted to papers and cases illustrative of the diseases of the lower animals. Works of this kind promise not only to prove useful to the class of practitioners to whom they are more especially addressed, but, not unfrequently, to afford valuable pathological hints to medical men. We think we cannot better explain the objects of the work than by giving a short analysis of the number for April now before us.

This number contains several rather interesting articles. Among these is a clever but rather grandiloquent disquisition by Dr. Patellani, of Turin, upon a solid bony tumor, of a tooth-like substance, preserved in the Veterinary College of Milan, which was found in the cerebral cavity of an ox; its form being similar to that of the brain. The

animal from which it was taken is stated to have been healthy, and to have attained the full size. The author says that Professor Tiedemann, to whom he mentioned the fact, was not astonished at hearing that the animal lived, in perfect health, with such a brain. He said that his medulla oblongata must have been very much developed, and likewise the nerves corresponding to the sinuses. The same opinion was likewise expressed by President Tomassini. The author succeeds in rendering it probable, by his statement of the anatomical and chemical characters of the concretion, that it once formed the greater part of the cerebral mass of the ox; but in endeavouring to prove that the animal to which it belongs must necessarily have been perfectly healthy, he loses the thread of his argument in a mist of transcendental perplexity.

The cases of “carditis in a bull,” and “melanosis in a horse,” are worthy of perusal. The latter disease, so rare in the human subject, is one of the most frequent and destructive maladies to which horses, especially those of a white or grey colour, are liable. Indeed, it has been stated that the larger proportion of grey horses die from this form of malignant disease.

There is also an interesting case of strangulation of the rectum in a filly, by one of the ovaria becoming pendulous and twisted around it. The ovarium was found loose, and constricted the rectum as tightly as if a ligature had been passed around it: it had inserted itself through a fold of the cellular membrane.

The following quotation is a proof that the profession of the veterinary surgeon occasionally well deserves to be termed a “pursuit of science under difficulties.” The author, Mr. J. Markham, was attending a horse affected with rabies. He says, “I proceeded to administer a cathartic ball, but before I could get my hand out of his mouth, a violent spasm came on, and he appeared similar to a horse having tetanus; the spasm continued for about a minute or two, but which seemed to me a very long time, as one of his tushes entered the under part of my wrist, and the other the back of my hand, which was anything but a pleasant situation to be placed in, since I could not tell how long the spasm

might last; but I happened to have the presence of mind to keep his tongue between his molar teeth, which prevented his jaws from closing so tightly as they otherwise would have done. My wrist was bitten very severely, one of the large tendons being divided, a portion of which protruding had to be excised." The author somewhat naively adds, it will be a caution to him in future never to attempt to give a rabid horse a ball!

A case is related of phrenic hernia in a horse, where it was found that nearly two yards of the ileum had passed through a laceration in the tendinous portion of the diaphragm, by the side of the opening through which the posterior cava proceeds, and become strangulated. Two days previous to his illness, the animal had been leaping over a bar, which might have been the immediate cause of this lesion.

It cannot be doubted that our knowledge of pathology would be greatly enhanced by a study of morbid anatomy in the lower animals. Various diseases which are rare, and imperfectly marked in the human subject, occur frequently, and are strongly developed, in many quadrupeds. Veterinary surgeons have evidently made great progress in the knowledge of this subject; indeed, the whole routine, both of their education and practice, appears to have assumed a strictly professional character. We are glad to see that, by a recent order, the veterinary surgeons of the French army are in future to receive the rank and pay of officers; and it is probable that the time will soon arrive when the well-educated surgeon of this class, will every where receive the consideration due to the practitioner of a liberal science.

To a reader who is not accustomed to works on veterinary medicine, the style of expression here used cannot fail to strike him at first as a kind of travestie upon medical writings, from its close adherence to the nomenclature adopted by physicians: but this impression soon wears off. We would, however, suggest to our veterinary friends that their adoption of the ordinary conventionalisms of the sick room—in calling a sick bull "the patient," for instance—has a somewhat ludicrous effect.

MEDICAL GAZETTE.

Friday, April 25, 1845.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medice* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."
CICERO.

ENGLISH AND SCOTCH GRADUATES UNDER THE NEW BILL.

IN a former article we alluded to a distinct class of practitioners created by the new Bill, under the name of "Inceptors in the Faculty of Medicine." We then stated that they were merely "licentiates" under another name, with one year added to the age, and that the necessity for the creation of such a class was highly questionable. Our attention has been more particularly recalled to this subject, by a letter addressed to Sir James Graham by Professor Quain, of University College*. This pamphlet differs from most of those which have appeared on the subject of the new Bill, in the temperate language in which it is written, and in the abandonment of medico-political views for a clear and logical exposition of some of the results which are likely to follow, if the clauses respecting the granting of medical degrees by British Universities and Colleges be retained in their present state. We have all along regarded the Inceptor class, as "cheaply-made" physicians—persons who, while they nominally take a higher rank, may in fact be inferior in qualifications to the licentiate in medicine and surgery. We here quote the clause respecting the Inceptor class:—

"And be it enacted, That it shall be lawful for any University of the said United Kingdom to grant the degree of Inceptor in the Faculty of Medicine, subject to the restrictions hereinbefore

* Observations on the Education and Examinations for Degrees of Medicine, as affected by the New Medical Bill, with remarks, &c. in a letter to the Right Hon. Sir James Graham, Bart. by Richard Quain, F.R.S. Professor of Anatomy in University College, London.

contained concerning medical degrees to any student of the same University who shall have attained the age of *twenty-two* years; and that every such graduate in the Faculty of Medicine, being also examined and having received letters testimonial of his qualification in the manner hereinbefore prescribed in the case of licentiates in medicine and surgery, shall be entitled to be registered by the said Council of Health as an *Inceptor in the Faculty of Medicine*, with all the rights, privileges and liabilities of a licentiate in medicine and surgery, subject to such general regulations as shall be made by the said Council concerning the registry of licentiates."

We can only account for the introduction of a clause of this kind by the fact, that it was objected to the former Bill, that it required so high a standard of education for a candidate to take the degree of doctor of medicine, as practically to make it a very restricted class. The remedy proposed in the present Bill is to create a lower order of physicians*, who, while they will have all the rights, privileges, and liabilities of licentiates in medicine and surgery, will certainly be inferior to them as professional men. So far from being an improvement, this is a retrograde step. We shall see, however, that the Scotch Universities are likely to be especially benefited if this clause should be retained; and, as farther results, owing to the greater facility in obtaining this degree thrown out by these Universities, that the class of licentiates will be small, the class of inceptors large, and the schools of London in great part abandoned for those of Edinburgh.

We can hardly believe that these portions of the new Bill, of which the unfair bearing upon the London schools has been so ably exposed by Professor

Quain, have been introduced with the deliberate intention of conferring a benefit upon one British University to the downright injury of another: we are inclined to adopt the more charitable view, that the Secretary of State cannot be aware of what are likely to be the real consequences of the Bill, should it become law.

The title of *Inceptor* is in many points of view objectionable. We can only suppose that it is intended to be a substitute for the degree of Bachelor of medicine. If it be not equivalent to this, or to some grade higher than this, it is impossible to conceive why the class should be created at all, for the privileges are no more than those of a "licentiate," with another name.

Now the question which we propose to consider is,—where are these Inceptors likely to receive their medical education, and to obtain their degrees? In discussing this question we shall make use of the pamphlet of Professor Quain. If one fact be more certain than another with regard to medical students, it is this, that under like privileges of practice, they will take out that degree which costs them the least trouble in regard to the period of study required, and the kind of examination which they have to undergo. Other considerations may also come into operation: for instance, the expense of studying for two years in Edinburgh is likely to be much less than that incurred in London. These matters, however, we lay aside, as of little importance compared with the benefits which the Northern University will, we believe, indirectly receive from the operation of the 22d and 23d clauses of the Medical Reform Bill. Again, admitting that under the new law, the "Inceptor" will possess the same privileges (see clause *suprà*) as the licentiate, with the bonus of an apparently higher grade, for the one

* Under the former Bill, bachelors of medicine at the age of twenty-two, could only be registered as licentiates in medicine and surgery. In the present Bill, the new class can register as "inceptors in the Faculty of Medicine." This appears to be nominally giving them a position above the licentiates.

would be a "University graduate,"—a Bachelor of medicine, *de facto*,—and the other a mere licentiate, it is we think obvious, that if greater facility be held out in a particular locality for obtaining the inceptorship, that locality will be especially favoured, and the licentiateship will be comparatively but little sought after. Such, we believe, will be the results of the present bill.

It has been long known that the Medical Faculty of the University of Edinburgh is opposed to that view which looks upon a good preliminary education in a candidate, as necessary to a graduate. This was plainly stated in their evidence before the Parliamentary Commissioners, many years since. In this view they differ from all who have written on the subject of medical education; and therefore, as it might have been reasonably expected, their opinions, unsupported as they were by any sound argument, were most unfavourably received by the Commissioners.

We select the arguments from Dr. Alison's report to the Commissioners, as quoted by Prof. Quain. The whole of the Faculty were stated to have concurred in these views, except the late Dr. Duncan. There are two principal grounds on which the pleading is rested.

"It lays down, that 'experience does not entitle us to say that the skill of physicians is by any means in proportion to their attainments in general literature and science. . . . In fact, we may safely assert, that the talents and habits of mind by which great and varied acquisitions of literature and science are made, and which a long-continued course of such study is calculated to form, are very different from those attainments by which the most judicious practitioners are distinguished. . . . Every medical man has besides to acquire habits of business, observation of mankind, and a knowledge of the world. These acquirements of themselves make up to many medical men for the want of scientific knowledge, but the knowledge

of all the sciences cannot make up to them for the want of those; and in general, I believe, we may say, that the habits of a student who has gone through a very long and varied course of literature and science, are not those which will fit a man for that kind of intercourse with the world, by which a physician must live.'"

We do not know that we can add to the force of the comments made by the Commissioners themselves upon this report; and as it is important to show that the present Medical Reform Bill is founded on principles entirely different from those which the Commissioners themselves recommend, we here reprint so much of their answer as bears upon the opinions of the Faculty respecting preliminary education:—

"The amount of this would seem to be, that literature is a positive evil to a physician; that it unfits him for the habits and state of mind which he ought to cultivate; and that it will be an obstacle to his success in practice. It is difficult to conceive that the learned medical faculty could have intended to go so far as this; but it is plain that there is much fallacy in the assertions, for it can scarcely be called reasoning, which they here adduce. It is unquestionably true, that if a man were to devote himself in the manner stated to literature and science, making these the chief, or almost the exclusive objects of his pursuit, he would not be a good physician: but this is not at all what is intended; the sole object being, that a physician should have that liberal education which is implied in a course of university attendance. By acquiring this, the mind would be invigorated for any intellectual pursuit, and it could superinduce no habit disqualifying for the activity of exertion, or for mingling in society as a medical man must do. Such education also, it is to be remembered, would be completed, or nearly so, before medical pursuits commenced, certainly long before practice was attempted, and would not therefore have the effect which is here supposed."

The grand argument for not making a good preliminary education a necessary

antecedent to medical studies remains to be explained; and we are sorry here to perceive that it partakes more of the "*argumentum ad crumenam*" than appears to us to be befitting in the Medical Faculty of any University. We know that fees will always be looked to more or less by all Universities; but if they are to be obtained by lowering the qualifications of graduates, they are obtained, to say the least, at the sacrifice of the respectability of the profession. It is like the circulation of a debased currency, for the adoption of which it would be a poor argument in a moral, although probably a fair one in a commercial light, that our neighbours were circulating coin which was inflicting pecuniary injury upon ourselves; therefore it may be said, we will, in self defence, lower our standard to exclude their currency. We can positively make nothing more than this out of the following argument, adduced by Dr. Alison, who, as Dean of the Faculty, speaks for his colleagues:—

"Unless it can be made quite clear that any additional qualifications which we (*i. e.* the University of Edinburgh) demand, will raise the value of the degree of our graduates *in the eyes of the public*, and *increase their chance of professional success*, the effect of making our degree more difficult of attainment will only be to increase the proportion of medical men practising upon inferior degrees, and to lower rather than to elevate upon the whole, the general average of the attainments of professional men."

We have placed two lines in italics, because it seems to us as if the standard of preliminary education were hereby made to depend upon the mere marketable value of a degree. The "*chance of professional success*" is well known to be very often greater with the quack and pretender than with the well-

educated physician; but is this a sufficient reason for any University lowering its standard to meet what may be a vitiated taste on the part of the public? Some may succeed as surgeons and apothecaries with diplomas obtained by a much less expensive education than that given in the University of Edinburgh, but we cannot agree that this is any reason for sinking the rank of physician in order to create a competing class, more especially when no better reason can be adduced than that without such a lowering of the grade, the University diploma would not be sought after. If men can acquire a right to practise "*with success and reputation*" without graduating as physicians in the University of Edinburgh, it plainly shews that the creation of a lower order of physicians is wholly unnecessary so far as the public are concerned; and, in relation to the profession, it can only be attended with the degradation of a highly respectable class. It is quite true that many may practise successfully with inferior qualifications, or degrees obtained elsewhere; but most of these practitioners would consider it an honour to obtain the highest degree—a feeling which can arise solely, as the Commissioners suggest, from the conviction that the having such a degree, would tend to increase their respectability and their practice. There is therefore no fair reason why the University should lower its grade. We hope to make it plain at a future time unless the intended alterations in the second Medical Reform Bill should render it unnecessary, that the "Inceptors" will exactly meet the wishes of the Medical Faculty, and that they will be able to procure their "*letters testimonial*" on much more favourable terms in the University of Edinburgh, than in any other University in the British dominions.

ON THE LATE CASE OF POISONING BY PRUSSIC ACID.

To the Editor of the Medical Gazette.

SIR,

Will you permit me to correct a very serious error which has appeared in the report given by Messrs. Hicks and Waterworth of a recent case of poisoning by prussic acid: it was published in the *MEDICAL GAZETTE* for the 11th inst. I am somewhat at a loss to know how this error has been committed, though it might have arisen from the perusal of some hasty notes which were given by me to Mr. Watson at the time I made the chemical analysis. In that report it is represented that the contents of the stomach had a smell of prussic acid, and that upon distilling them I obtained two drachms of a clear fluid having the odour of hydrocyanic acid, and giving, both with the iron and silver tests, ample evidence of its presence; moreover, that I obtained cyanogen gas from it, which burned with the characteristic purple flame. Now the latter part of this statement is altogether erroneous, for though the fluid as well as the contents of the stomach had the smell of hydrocyanic acid, yet the chemical evidences were so feeble, that if I had not been guided by the odour, I am convinced that they would have been passed by without any special notice; indeed, the nitrate of silver, which is by far the most delicate of the chemical tests, only gave a slight turbidity to the fluid, and it would have been perfectly impossible to have collected any from it, or to have procured any cyanogen from it. It is very true that I showed the combustion of the cyanogen gas, but this was from the remainder of the lotion of which deceased had taken one dose. The importance of this correction must be evident to every one, for if it is proved that deceased took only one grain of anhydrous prussic acid, and that I was able some time after her death to detect prussic acid in her stomach in such a quantity as to collect and burn its cyanogen, it will very naturally be supposed that much less than one grain would have been sufficient to destroy life. This, however, is a conclusion which I am not at all prepared to admit, nor do I think the question of a minimum fatal dose, so very important in a medico-legal point of view, will admit of a satisfactory answer, for there are too many circumstances which affect the operation of this poison. In experimenting upon animals, I have found that any debilitating cause will increase its activity, and thereby render the action of an otherwise small and harmless dose fatal; thus, for instance, fatigue, want of food, loss of blood, or disease, are all circumstances having this

effect. In this case it would appear that deceased, who was a Jewess, had been keeping the passover; it is a fact that only a little bisenit was found in her stomach.

I am, sir, yours, &c.

H. LETHEBY, M.B.

[We insert so much of Dr. Letheby's letter as bears upon the case of poisoning by prussic acid, published in our number for April 11th. The rest of his letter consists of criticism on matters which have no connexion with that case.]

In relation to the "*very serious error*" to which Dr. Letheby refers, we extract the following from a letter addressed to us by Mr. Hicks, in answer to an inquiry respecting his authority for the statement:—

"I was indebted to Mr. Watson for that part of my case alluding to the chemical tests, and I find I was in error so far as relates to the burning of the cyanogen; by way, however, of proving the correctness of my statements in all other respects, I send an exact copy of Dr. Letheby's own writing, as regards the means used for the detection of the poison, together with the tests and their results.

The bottle containing the fluid from the stomach, amounting to two ounces in quantity, was distilled in a water-bath, and about one drachm of a clear liquid came over; this smelt faintly of prussic acid, and gave chemical evidence of its presence by the iron and silver tests.

Tests.—1. The distilled fluid smelt of prussic acid. 2. A little was mixed with a double salt of iron, the sesquichloride, and then with a little liq. potassæ; to this was added a drop or two of muriatic acid, and a bluish yellow tinge resulted. 3. The remainder was mixed with a solution of nitrate of silver; a white turbidity resulted, which disappeared on boiling with nitric acid—a proof of its being cyanide of silver. The quantity of prussic acid was so small as not to be ascertained."

T. B. HICKS.

4, High Street, Newington,
April 16, 1845.

REMARKS.—Dr. Letheby complains that Mr. Hicks stated that the tests gave "*ample*" evidence of the presence of the poison; but this word "*ample*" does not occur in Mr. Hicks's report of the case; and the only error that we can perceive is, that there was not sufficient cyanide of silver obtained from the contents of the stomach to allow of the burning of cyanogen. The effects of the tests, taken in conjunction with the odour, appear to establish clearly that prussic acid was present in the stomach, although not in so large a quantity as Mr. Hicks had supposed. We are at a loss to perceive how Dr. Letheby can con-

vert this into a "very serious error;" the "*chemical evidences*," he admits, were "feeble;" still, as we interpret his meaning, he had no doubt of the presence of the poison in the contents of the stomach, and the feebleness of the tests was compensated by the distinctness of the odour. If he had even collected enough cyanide of silver for applying the test of combustion, we do not see how this would have made the case so very extraordinary as he represents. The twentieth part of a grain of anhydrous acid will furnish a sufficient quantity of cyanide of silver for the experiment. With regard to the effects of debility in modifying the action of all poisons, this has been long known. From Mr. Hicks's description, however, we should not imagine that the alleged debility from fasting had had any material influence in this instance: it is highly probable, from the report, that the deceased would have died from the dose taken, whether she had been keeping the passover or not*. The most interesting facts connected with the case were—1, that the whole of the symptoms during life, and appearances after death, were accurately observed and recorded; and 2d, that the dose which destroyed life was determined by the analysis of a part of the liquid swallowed. Whether the poison was found in the stomach or not, and whether a sufficient quantity of cyanide of silver was procured to yield cyanogen by heat or not, are matters of a subordinate description. Dr. Letheby admits that prussic acid did exist in the stomach, but the quantity was too small to yield enough cyanide of silver for procuring cyanogen.—*ED. GAZ.*]

MEMOIR OF THE LATE DR. HEBERDEN.

(*From a Correspondent.*)

[WE are induced to give insertion to the following memoir of an excellent and amiable physician, from the fact that the name of "Heberden" has been long and respectably known in the medical profession.—*ED. GAZ.*]

DR. HEBERDEN, the subject of the present memoir, was born in the year 1767, at the house of his father, in Cecil Street, and at the early age of seven years was sent to school at the Charter-house, where he acquitted himself with much credit, rising to the head of the school, and bringing away with him testimonials of regard from Dr.

Beardmoor, who was then head master. He was afterwards at St. John's College, Cambridge, distinguishing himself in the mathematical tripos at his B. A. degree in 1788, and subsequently gaining, by his pre-eminence in classical knowledge, the chancellor's medal, the members' prizes on two several occasions, and one of the few open Fellowships in his College, which, though of no great emolument, was a source of gratification to him, and during the few years which elapsed, previously to his entering upon the more arduous business of life, he often resorted to Cambridge in the quieter months of the summer, and availed himself of the facilities which were there afforded him of indulging his literary pursuits. Afterwards he went up to London, and applied himself more exclusively to the duties of his profession, attending at St. George's Hospital, and devoting himself to the business under all the advantages of the counsel and long experience of a father who had so successfully run the same course before him. In 1797 he became a Fellow of the College of Physicians, and soon obtained a tolerably extensive practice. On the death of his father, in 1801, he removed from Dover Street, where he had previously resided, to his house in Pall Mall, where he lived in the highest enjoyment of domestic comfort, and of friends remarkable for the high position they held in their various professions, and for the general reputation they possessed among the wise and good. Few men, indeed, have attained to higher qualifications as a companion. The varied nature of his acquirements, the extensiveness of his information, the untiring satisfaction with which he never ceased to read and admire the excellencies of the best authors in poetry and prose, the retentiveness of his memory, the accuracy of his knowledge, the eager interest he exhibited in everything that was useful and praiseworthy, with his perfect freedom from all pedantry and affectation, could not fail to secure to him the esteem of those who had the happiness to know him. Concurrently with general learning, the special interests of his profession moved onward. From a student in St. George's Hospital he became physician there, and soon was brought before the public as the editor of his father's "*Commentarii de morborum historia*," together with an English translation; shortly afterwards, he was known as the author of "*Epitome morborum puerorum*," and being a Fellow as well of the Royal Society as of the College of Physicians, he was also an occasional contributor to their papers. It may be mentioned, also, that on other subjects his facility of writing, either in prose or verse, was frequently put in requisition, and the beautiful inscription on the statue of Addison, in Westminster Abbey,

* We shall shortly have occasion to insert a case of poisoning by corrosive sublimate, where forty grains of that powerful irritant were taken by a woman fasting, but this debilitating cause, so far from increasing the activity of a small dose, assisted the woman in recovering from the effects of a large dose. Upon theoretical principles this woman ought to have died!

is from his pen. In 1806 he was appointed physician to Queen Charlotte, and on the death of Sir George Baker, in 1809, was made physician to His Majesty King George the Third, by whom he was more than once offered a baronetcy, with a pension, in the most gracious manner,—distinctions, however, which his own feelings induced him to decline. While thus in much prosperity, having attained in all periods of his life the highest honours to which his studies or his profession could lead him, and being in the full enjoyment of the reputation they carried with them, he was suddenly, in 1812, left a widower with nine young children. Every thing was at once sacrificed to the sense of duty by which he felt himself called upon to superintend the highest interests of the children committed to his charge. The charms of general society, the excitement of professional engagements, each having strong claims upon an intellectual and active mind, were abandoned cheerfully for the wearisome and unostentatious duties of watching over an infant family, and administering to their comfort. His practice as a physician was now restricted to his attendance at Windsor Castle, and this alone interrupted, even for a day, his devotion to his children. Under the suspension of the more bustling engagements of life, he retired to the little village of Datchet, in Bucks, where he lived for fourteen years, surrounded by his books, and rather avoiding than courting society. During this period he printed, and dedicated to his children, a translation from the moral works of Plutarch, on Brotherly Love, and he had previously written and published a little treatise on General Education, which, of themselves, sufficiently attest the anxious occupation of his mind. As he obtained further leisure, he amused himself with translating Cicero's letters to Atticus, which he subsequently published in two volumes octavo. In 1826, having attained his purpose in absenting himself from London, he returned thither again, partly with the design of affording to one of his sons, then entering upon the preliminary studies of a physician, that information and encouragement which he had himself received with so much delight from a parent's lips. It was at the same hospital in which he had acquired his own first practical knowledge, that his son, a most promising young man, and eager in his profession, was present at a post-mortem examination, in which he was greatly interested, when incautiously taking into his hand, which was slightly punctured, a portion of the body, the deadly virus so affected him that within a week he died. The grief of this loss never ceased to create a melancholy interest in every thing relating to his profession. In the following year (1829) he lost another

son, and in four years afterwards his eldest daughter, the fond companion of his former widowed years. Under this succession of afflictions fast falling upon him, it may be inferred how his mind was engaged from the writings which then appeared; for in 1830 he published his *Reflections on the Gospel of St. John*; in 1836 he printed a translation of the Catholic epistles, which was circulated among his friends; and in 1839, at their request, he published a translation and running commentary on the whole of the apostolical epistles and the Book of Revelation.

Amidst the many panegyrics which justice, or charity, or affection, bestow on departed worth, it is seldom that we are able to point to such unequivocal proofs of merit in all the stages of life; to such tokens of what the learned Barrow has well styled, "Industry in his general calling as a christian; industry in his particular calling as a scholar and a gentleman." While these more prominent features in this brief history are within the reach of public inquiry, private friendship only can disclose the warmth of his affection, the gentleness of his manners, the charity of all his sentiments, his generous disregard of money, the extent of his benevolence, and his inflexible adherence to the strictest truth, from which no circumstances of difficulty or delicacy could ever induce him to swerve; and, above all, the unaffected piety, and undoubting confidence in the wisdom and goodness of every dispensation of Providence, which influenced all his conduct, and supported him with unruffled serenity to the last moment of his life. He died at his house in Cumberland Street, on the 19th of February, 1845, and was buried in his family vault in the parish church of Windsor.

CASE OF HYDROCELE.

To the Editor of the Medical Gazette.

SIR,

If you think the following case, in which a hydrocele had been allowed to acquire an enormous size, and which was cured by the simple injection of a solution of sulphate of zinc, of sufficient interest to your numerous readers, you will oblige me by inserting it.

I am, sir,

Yours very obediently,

JOHN M. BURTON.

Croom's Hill, Greenwich,
March 23, 1845.

I was consulted in March 1839, by a farmer of the name of Lynn, residing at some distance in the country, respecting a hydrocele, of which he had been for many years the subject, but for which he had never

previously asked advice, from having been told that he would have to undergo a dangerous operation for its cure.

He stated that he was 45 years of age, and had always enjoyed good health. About fifteen years since he received a violent blow on the right testis by being thrown forwards on the pommel of his saddle. The blow was followed by considerable pain and swelling, which subsided in a few days, leaving, however, a pyriform tumor, about the size of an orange; this tumor, which gave him no pain, did not alter in size or appearance until about three years since, when it began to enlarge, and gradually increased to its present size. It now extends to within three inches of the knee, and causes great inconvenience from the mechanical impediment it affords to progression, and also from its weight; from the constant friction, the skin of the scrotum and inside of the thigh has become abraded and ulcerated to a great extent. On tapping the swelling, I drew off five pints of a turbid brown coloured fluid.

He immediately experienced great relief, and was directed to keep upon his back.

August 22d. — I tapped the swelling again, and drew off a pint and a half of clear straw-coloured fluid, and then injected the same quantity of water, holding 5j. Zinci Sulph. in solution. This was retained four minutes, and produced no great amount of pain.

24th. — He had severe pain in the afternoon after the operation, which lasted all the next day, but has now subsided. The sac is as large as two fists, very hard, and of great weight; the scrotum hangs loosely to a distance of, at least, three inches below the lowest part of the swelling.

27th. — Scrotum resumed its natural appearance, having regained its elasticity; it embraces the swelling now pretty closely: this remains of about the same size.

April 15th. — Tumor diminishing, is not so solid; slight fluctuation anteriorly. Infric. Ung. Iodinæ c. Hydrarg. nocte et mane.

May 6th. — Tumor now of the size of a small orange, and firm. The epididymis to be felt rather enlarged. Pergat.

June 5th. — Tumor about the size of an egg. Omittit Ung.

July 26th. — There is scarcely any difference between the testicle on the sound and that on the affected side. He suffers no inconvenience, and says he feels himself relieved from a most oppressive burden.

IMPROVED KIND OF LIGATURE.

DR. THOMAS M. LEE observes, that "in using the common double ligature, he has oftener than once experienced a good deal of inconvenience—when the patient was uneasy, from the necessity for some manipu-

lation—in order to ascertain which were the ends of the one, and which of the other thread." It has occurred to Dr. L. that the apparatus alluded to might be rendered much more perfect by having one-half of each thread intended for a double ligature dyed black, while the other half is allowed to retain its original light colour. The advantages of this plan are, that after the needle is cut away, the two ends of each thread can be easily seized and tied, saving the patient from the anxiety which delay occasions. The difference in colour at once distinguishes the one ligature from the other, so that there is no need for any pulling at the different ends to gain this information. The preparation of this thread is very simple, one-half only of each hank having to be dipped into the dye. The hank thus prepared may then be cut through, either at one point in its circumference where the black and white parts meet, or at two, viz. in the middle of the white, and again, in the middle of the black part.—*London and Edinburgh Monthly Journal*, March.

MEDICAL INTELLIGENCE.

THE second reading of the Medical Profession Bill has been fixed by Sir James Graham for this evening. Certain alterations and amendments are in contemplation, although the nature of these is not stated. The principle of the Bill, so far as regards equality of qualification, or an equal right to practise throughout the United Kingdom, will be preserved,—a principle to which we think all reasonable men must give their concurrence. It is proposed that after the second reading the Bill shall go into Committee *pro forma*; but that the alterations and amendments will not be discussed in Committee until after the new Bill has been circulated through the country for at least a fortnight. This discussion will not probably come on before the latter end of May.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Members admitted to the Fellowship, April 17, 1845.—E. Canton, St. Martin's Lane.—W. W. Cooper, Tenterden Street.—W. E. Crowfoot, Beccles.—H. Davis, Tenbury.—J. E. Erichsen, Welbeck Street.—G. Harcourt, Chertsey.—W. A. Hillman, Argyll Street.—E. Jackson, Chaddeley Corbett.—A. Keyser, Norfolk Crescent, Hyde Park.—W. T. Lucas, Featherstone Buildings.—R. G. Shute, Mecklenburgh Square.—J. Stilwell, Uxbridge.—C. M. Vowell, St. Helena.—J. T. Ware, Russell Square.—J. L. White, Dowlais.

List of Gentlemen admitted Members, April 11.—J. Gardner.—R. R. Jefferiss.—

C. Muscroft.—W. M'Hugh.—J. C. Wordsworth.—W. H. Thornton.—T. B. Horne.—T. A. H. Dodd.—R. R. Noble.—R. S. Cross.

14th.—T. Atchison.—J. Palmer.—J. Richardson.—J. T. Griffith.—F. Blake.—J. T. C. Ross.—A. Priest.—T. G. Stockwell.—J. Vass.—W. G. Dalgarns.

18th.—E. Snell.—J. Duncan.—T. Fisher.—T. Alderton.—P. Roscow.—E. C. Odling.—W. Lightfoot.—R. Abud.—J. Ody.—W. Smith.—J. Hewett.—T. D. Scott.

21st.—R. S. Finch.—C. Vicary.—B. Mickethwaite.—H. Wiglesworth.—R. M. Bowman.—F. H. Johnson.—G. A. Hallion.—J. C. Austen.—F. Frampton.—E. Cripps.

APOTHECARIES' HALL.

Gentlemen who have obtained Certificates, April 10.—J. Lewis, Treleach, Carmarthen-shire.—R. Appleton, Munslow, Salop.—H. E. Cullen.—W. T. Iliff, Newington Butts, London.—N. Kennicott, Monkwearmouth.—J. Wallace, Carshalton.—D. S. Penrice, Great Yarmouth.—E. Martin, Bristol.

17th.—F. H. Harris, Botesdale, Suffolk.—W. Tickell, Looe, Cornwall.—D. Davies, Pant Einon, Cardiganshire.—S. W. Burbury, Birmingham, Warwickshire.—W. Hoar, Maidstone, Kent.—J. W. H. Mackenzie, Cheadle, Staffordshire.—T. H. Smith, St. Alban's.

NOTICES TO CORRESPONDENTS.

"**MEDIATOR.**" The writer of the letter signed "**Mediator**," in our last week's number, wishes the following corrections to be made. At page 940, col. 2, line 19 from top, the sentence should stand:—"In regard to the period to which admission to the fellowship by seniority should have been extended, I think liberality ought to have been manifested." Farther on, after the word "**successors**," the following has been omitted—"but of all members of the profession these gentlemen ought to be, and I have no doubt are, best qualified to pass the requisite examination; and to that test they should have been subjected, if they did not choose to wait their turn of seniority." A fresh paragraph ought then to have commenced as follows:—

"The arrangement which I have suggested cannot now be carried into full effect, as the fellows who have been appointed cannot be deprived of their titles; but it is worthy of deliberate consideration," &c.

Without these corrections and additions the letter is quite unintelligible. I therefore beg your insertion of them.

The communications of Dr. Jago, Dr. Rowland, Mr. Stewart, Mr. Tomes, and

other correspondents, have been reserved for the new series.

We shall be glad to insert in the new series, the papers on Malingering by Mr. F. Calder.

"**Idios.**" We are in arrears with so many correspondents that we regret we cannot find room for the letter.

Dr. Golding Bird. A proof shall be forwarded.

MORTALITY OF THE METROPOLIS.

Deaths from all causes registered in the week ending Saturday, April 12.

ALL CAUSES	906
SPECIFIED CAUSES	905
I.—Zymotic (Epidemic, Endemic, and Contagious) Diseases, 155; among which, of—	
Small Pox	16
Measles	18
Scarlatina	17
Whooping Cough	50
Croup	6
Thrush	3
Diarrhoea	4
Dysentery	3
Cholera	0
Influenza	1
Typhus	26
II.—Dropsy, Cancer, and other Diseases of uncertain or variable Seat, 87; among which, of—	
Hæmorrhage	0
Dropsy	30
Scrofula	3
Cancer	11
Atrophy	10
Debility	16
Sudden Deaths	5
III.—Diseases of the Brain, Spinal Marrow, Nerves, and Senses, 141; among which, of—	
Hydrocephalus	30
Apoplexy	18
Paralysis	14
Convulsions	42
Insanity	1
Delirium Tremens	1
IV.—Diseases of the Lungs, and of the other Organs of Respiration, 318; among which, of—	
Pneumonia	84
Hydrothorax	4
Asthma	30
Phthisis or Consumption	146
Diseases of the Lungs, &c.	22
V.—Diseases of Heart and Blood-vessels	39
VI.—Diseases of the Stomach, Liver, and other Organs of Digestion, 67; among which, of—	
Teething	16
Gastritis	0
Enteritis	12
Tubercles	7
Hernia	1
Disease of Stomach, &c.	4
Disease of Liver, &c.	9
VII.—Diseases of the Kidneys, &c.	8
VIII.—Childbirth, Diseases of the Uterus, &c. 15; among which, of—	
Childbirth	11
Disease of Uterus	3
IX.—Rheumatism, Diseases of the Bones, Joints, &c.	5
X.—Diseases of Skin, Cellular Tissue, &c.	1
XI.—Old Age	54
XII.—Violence, Privation, Cold, and Intemperance	15

WILSON & OGILVY, 57, Skinner Street, London.

INDEX TO VOL. XXXV.

(VOL. I. FOR THE SESSION 1844-45.)

A.

Abercrombie, Dr. John, death of, 336.
 Abstract of the most material facts of the controversy between Dr. Lee, of London, and Dr. Paterson, of Leith, relative to the structure of the corpus luteum, 494.
 Abscess of the abdomen, Mr. Arnott's clinical lecture on a case of, 401; of the labium pudendi, 402; of the side, 403.
 Abscess in the abdominal muscles, Mr. William Smith's case of, with disease of the pubic bones, 517.
 Acesius: a survey of the ethical relations of medicine, by Dr. Marx, 14, 51, 87, 102, 113, 184.
 Address of the Society of Apothecaries, editorial observations on the, 258.
 Addison, Mr. William, on the transformation of pus-cells into a mucous or fibrous tissue, 69, 250.
 Alison's, Dr. Somerville Scott, medical cases:—small stomach, 135; ossification of gall-bladder, 137; hypertrophy of the heart, *ib.*; case of hydatid tumor of the liver, with remarks, 18; on the state of the poor in Scotland, 310; on pericarditis, a complication and sequela of scarlatina, 664.
 Allnatt, Dr. on ergotization of the tipulidæ by hydrocyanic acid, 675; on hepatalgia, 796.
 Alum and opium, the combination of, recommended by Dr. Hoffmann in cases of lead colic, 207.

Amaurosis, case of, occurring suddenly, 240.
 Ammonia given off by albuminous fluids, 750.
 Amnesia complicating acute rheumatism, Dr. Linsem's case of, 304.
 Amussat's, M. case of lumbar enterotomy, without opening the peritoneum, performed with success upon a woman aged 53, 269; researches on the wounds of blood-vessels, 496.
 Analysis, comparative, of the food consumed, and the excrements passed, by a turtle-dove, 399.
 Aneurism, Dr. Brereton on a case of, 398.
 Aneurism of the right subclavian artery, Mr. Aston Key's case of, 334.
 Aneurism, Mr. Erichsen's translation of the works of the principal writers on, reviewed, 801.
 Ankle-joint, Mr. Stafford on a case of compound dislocation of the, 327.
 Apothecaries' Hall, lists of gentlemen who have received certificates, 32, 64, 96, 176, 208, 240, 272, 304, 368, 432, 464, 624, 656, 688, 756, 784, 816, 848, 880, 912, 944, 976.
 Apothecaries, proposal to establish a Royal College of, 396.
 Apoplexy, Dr. Edward Blackmore on the cure of, 855.
 Arnold, the Rev. Dr. some particulars connected with the death of, 62.
 Arnott's, Mr. clinical lecture on a case of abscess of the abdomen, 401.
 Arnott's, Dr. A. description of the operation of lithotomy as performed by a native hakeem, 621.
 Arnott, Dr. James, on the present state of therapeutical inquiry, 407, 474, 481.

- Arsenic, remarkable case of poisoning with, related by Professor Wöhler, 655.
- Arsenic, on determining the quantity of, and at the same time obviating the inconveniences encountered with Marsh's apparatus, 716.
- Arsenic, Dr. Krafft's case of poisoning by, treated with hydrated oxide of iron, 750.
- Association of general practitioners, objection to the, 812.
- Assistants, unqualified, and medical pluralities, remarks on the injury done by, to the regular practitioner, by a Member of the North of England Association, 240.

B.

- Baker *versus* Lowe, remarks upon the recent trial in the Court of Queen's Bench, 733.
- Baly, Dr. W. on the mortality in prisons, and the diseases most frequently fatal to prisoners, 740.
- Ballingall's, Sir George, outlines of military surgery, reviewed, 547.
- Barlow, Dr. on the depuration of the blood, 269.
- Bartlett's, Mr. Thomas, observations on syphilis, 73.
- Basedow's, Mr. case of luxation of the head, and fracture of the neck of the thigh-bone, 367.
- Baths for the million—baths for the individual, 590.
- Bell's, Mr. Jacob, concise historical sketch of the progress of pharmacy in Great Britain, reviewed, 161.
- Bessens's, M. case of empalement without visceral injury, 846.
- Bethlem Hospital, regulation for the admission of pupils at, 264.
- Bile, Dr. George Kemp on the functions of the, 76.
- Birmingham and Midland Districts Medical and Surgical Association, meeting of the, 875.
- Bird, Dr. Golding, notice by, of the crystalline form of carbonate, and discovery of the oxalate of lime in the urine of herbivora, 49; account of Professor Mulder's researches on the chemical physiology of red colouring matter of blood, 415; his work on urinary deposits, reviewed, 419.
- Blackmore's, Dr. Edward, observations on the more important diseases of the nervous system, with illustrative cases, 569, 596, 630, 671, 699, 723, 760, 789, 822, 855, 917, 934.
- Bladder, Dr. Thienemann's case of ligature of a polypus of the, 175.
- Bleeding, Dr. Mayo on, in cases of congestion, 146.
- Blindness, sudden, Dr. Synnot's case of, 160.
- Blood, Dr. Andrew Buchanan on the white or opaque serum of the, 11.
- Blood, Mr. Golding Bird's account of Professor Mulder's researches on the chemical physiology of red colouring matter of the, 415.
- Blood, Dr. G. O. Rees on the, principally in regard to its physical and pathological attributes, being the Gulstonian Lectures for 1845, 753, 826, 849.
- Blood, Mr. Prescott Hewett on the extravasation of, into the cavity of the arachnoid membrane, 684.
- Blood, Mr. Gulliver on the formation of the buffy coat of the, 687.
- Blood-vessels, M. Amussat's researches on the wounds of, 496.
- Boards of Guardians, remarks by Mr. Porter on the conduct of, towards district medical officers, 735.
- Bone, M. Flourens on the formation of, 68.
- Books, analyses and notices of:—
Braithwaite's retrospect of medicine and surgery, 24.
Miller's principles of surgery, 89.
Mr. Samuel Cooper's introductory address to the students of University College, at the opening of the winter session in the faculty of Medicine, 1844-45, 117.
Dr. Davies's exposition of the laws which relate to the medical profession in England, 161.
Mr. Jacob Bell's sketch of the progress of pharmacy in Great Britain, 161.
Graefenberg; or a true account of the water-cure, by H. H. Graham, M.D. 199.
Dr. Guy's principles of forensic medicine, 227.
Guy's Hospital reports, No. 4, 256, 454.
Sir G. Lefevre's apology for the nerves, 290.
Medico-Chirurgical Transactions, vol. 19, new series, 325.
Kæmütz's complete course of meteorology, 355.
Dr. Golding Bird on urinary deposits, 419.
Dr. Christison's treatise on poisons, fourth edition, 450.
Mr. Greenhow's medical report of the case of Miss H— M—, 438.
Mr. Radford on galvanism, applied to the treatment of uterine hæmorrhage, 490.
Sir George Ballingall's outlines of military surgery, 547.
Statistics of recruiting, 550.
Mr. Quain's anatomy of the arteries, 586.
Dr. Hall on the nature and treatment of some of the more important diseases, medical and surgical, including the principal diseases of the eye, 613.

- Dr. Wagner's elements of the comparative anatomy of the nervous system, 649.
- Dr. William Gregory's outlines of chemistry, 673.
- Contributions towards a fauna and flora of the county of Cork, 680.
- Dr. Marshall Hall's practical observations and suggestions in medicine, 710.
- Mr. Durlacher's treatise on corns and bunions, 717.
- Messrs. Goodsir's anatomical and pathological observations, 736.
- Mr. Peschel's elements of physics, 737.
- Dr. Mulder on the chemistry of vegetable and animal physiology, 774.
- Mr. Newnham on human magnetism, 777.
- Observations on aneurism, selected from the works of the principal writers on this disease, and translated by Mr. Erichsen, 801.
- London Medical Directory, 802.
- Mr. Moore on the structure of the lungs, *ib.*
- Mr. Strauss's remarks and comments on the medical and chemical evidence adduced at the trial of John Tawell, 860.
- Schenlein's clinical lectures, 866.
- Sir J. M. Tierney's observations on variola vaccina, or cow-pock, 868.
- Dr. Wells's essay upon cretinism and goitre, *ib.*
- Dr. Furnivall on the diagnosis, prevention, and treatment of diseases of the heart, and of aneurism, 897.
- Mr. Mortimer on the growth of children's teeth, 927.
- The Veterinary Record, and transactions of the Veterinary Medical Association, April 1845, 967.
- Boussingault's, M. comparative analysis of the food consumed, and the excrements passed, by a turtle-dove, undertaken with a view to ascertain whether or not there is any exhalation of azote during respiration in the granivora, 399.
- Bourgery, M. on the relations in point of weight of the nervous parts of man and some animals, 462.
- Brain, Mr. Solly's contributions to the pathology of the, 245.
- Brain, Mr. John Chatto on a case of absence of a portion of the, 487.
- Braithwaite's, Mr. retrospect of practical medicine and surgery, reviewed, 24.
- Breath, offensive, Dr. A. L. Wigan on a remedy for, 224.
- Brereton, Dr. on a case of aneurism, 398.
- British Medical Association, communication from the Society of Apothecaries to the, 496.
- Brodie, Sir Benjamin, note from, 265.
- Buchanan, Dr. on the white or opaque serum of the blood, 11.
- Burial-clubs, Mr. Clay on the influence of, on the mortality, 209.
- Butterflies, uric acid excreted by, 623.
- C.
- Calculus, M. Lassaigne on a new species of, found in the kidneys and ureters of a bitch, 622.
- Calculi, urinary, of reptiles, M. Duvernoy on the, 207.
- Capillaries of the head, Mr. T. W. King's practical reflections on the, 252.
- Carbon, Mr. Rigg's experiments on the promotion or secretion of, by animals, the disappearance of hydrogen and oxygen, and the generation of heat during the process, 220.
- Carbonate of lead, Mr. John Shaw's case of poisoning by, 240.
- Carter, Mr. C. T. on the organization and protection of the medical profession: the Quarterly Review, &c. 605.
- Carter's, Mr. remarks on the amended medical bill, 830.
- Caries, Mr. Samuel Maclean's description of a modification of the spherical-headed cutter for the excision of, 539.
- Carus's earth-life, a specimen of ideal physiology, 39.
- Chatto, Mr. mesmerism applied to surgical operations, 351.
- Chatto's, Mr. John, case of absence of a portion of the brain, 487.
- Chatto, Mr. on the employment of mesmerism during surgical operations, 603.
- Chemistry, importance of the study of, 730.
- Child's, Mr. new hemorrhoid needle, 925.
- Chisholm's, Dr. case of excision of nearly one-half of the lower jaw, 46.
- Christison's, Dr. treatise on poisons, review of the fourth edition of, 450.
- Chronic cases, Dr. Mayo's record of, treated with partial or entire success, in which morbid changes of the cerebral or spinal system have existed, or have been threatened, 352.
- Clay, Mr. on the influence of burial-clubs on the mortality, 209.
- Cleft palate, Mr. Fergusson's observations on, 389.
- Coal as fuel, when first used, 879.
- Cole, Mr. on a case in which a foreign body was impacted in the throat, 127.
- College of Physicians, new charter to the, 779.
- Collier's, Mr. case of accident to the shoulder-joint, 925.
- Colon strangulated by the meso-colon, Dr. Gilman Davis's case of, 847.
- Colostrum of the cow, Dr. Davy on the, 933.

- Contributions towards a fauna and flora of the county of Cork, 681.
- Conversazione at the Royal College of Physicians, 558.
- Congestion, cerebral, Dr. Mayo on a case of, 17.
- Congestion, Dr. Mayo on bleeding in cases of, 146.
- Cooper's, Mr. Samuel, introductory address to the students of University College, at the opening of the winter session in the faculty of medicine, 1844-45, 117.
- Cooke, Mr. W. on the medical treatment of the case of the Rev. Dr. Arnold, 62.
- Corpus luteum, Dr. Robert Lee on the, and its value as a test of early pregnancy, 150.
- Corpus luteum, abstract of the most material points of the controversy between Dr. Lee, of London, and Mr. Paterson, of Leith, relative to the structure of the, 494.
- Corpus luteum, Dr. Paterson on the structure of the, 640.
- Corpora lutea, reply by "Scrutator" to Dr. Paterson's remarks on the, 709.
- Cotton, Mr. Charles, on the propriety of the refusal by hospital surgeons to countenance mesmerism, 427.
- Cough of twelve months' duration, Mr. Fearnside's report of a case of, treated in University College Hospital, 177.
- Cough, Dr. Mayo's report of a case of, with occasional hæmoptysis, treated by him in the St. Marylebone Infirmary, 485.
- Creosote in *nævus maternus*, recommended by Dr. Thornton, 176.
- Cyanides, Dr. Lethely on the poisonous effects of the, 603, 676.

D.

- Dalrymple's, Mr. John, sketch of a bill for the better regulation of the medical profession, 167.
- Dancing over the dead, 457.
- Daniell's, Mr. W. F. observations on the medical topography, climate, and diseases of the bights of Benin and Biafra, 435, 515, 582, 643, 706, 771, 886.
- Davies's, Dr. exposition of the laws which relate to the medical profession, reviewed, 161.
- Davis's, Dr. Gilman, case in which the colon was strangulated by the meso-colon, 847.
- Davy, Dr. on the colostrum of the cow, 933.
- Deformities, Mr. Tamplin's lectures on the nature and treatment of:—

LECT. 1.—*Talipes varus non-congenitus*, 33; *talipes valgus*, 36.

LECT. 2.—Treatment of *talipes valgus*, 65; *talipes equino-varus*, 67; *talipes equino-valgus*, ib.; treatment, 68.

LECT. 3.—*Talipes valgus*, 129.

LECT. 4.—*Talipes calcaneus*, 241; congenital deformities of the foot, 142; non-congenital deformities of the foot, 243.

LECT. 5.—Deformities of the knee-joint, 305; *genu valgum*, or knock-knee, ib.; *genu valgum* with outward inclination of the opposite knee, 307; *genu valgum* with curvature of the bones, ib.

LECT. 6.—Treatment of *genu valgum*, or knock-knee, by general means, mechanical, and surgical and medical, 369; *genu extorsum*, or outward inclination of the knees, 371; treatment, ib.

LECT. 7.—Division of the *vastus externus* and *fascia lata* for knock-knee, 465; relaxed condition of the ligaments of the knee-joint, admitting of undue motion antero-posteriorly, ib.; treatment, 466; contraction of the knee, commonly called *ankylosis*—congenital, ib.; non-congenital, 467; causes acting directly, ib.; injuries of various kinds, ib.; inflammation simply, 468; rheumatism, ib.; scrofulous disease, or "white swelling," with abscesses about the joint, 469; indirect causes, 473; injuries to the spine—cerebral or spinal irritation, 473.

LECT. 8.—Treatment of contraction of the knee-joint in the flexed position—mechanical and surgical, 561; means of forming a diagnosis, ib.; case of contraction from inflammation successfully treated mechanically, ib.; signs which may be considered favourable, 562; signs which are unfavourable, ib.; section of the *semi-membranosus*, *semi-tendinosus*, and *biceps*, ib.; mode of performing the operation, ib.; contraction of the *gastrocnemius* as a consequence, 565; contraction of the flexors and adductors of the hip as a consequence—treatment of, ib.; dislocation backwards of the tibia on the femur—treatment of, 567; dislocation backwards of the tibia on the femur—treatment of, 587.

LECT. 9.—Contraction of the knee-joint in the straight or extended position—congenital—non-congenital, 657; case of congenital contraction of the thighs, knees, and feet, ib.; causes of non-congenital contraction, 658; treatment—surgical and mechanical, ib.; division of the *rectus femoris*, ib.; contraction of the hip-joint—congenital—non-congenital, 659; causes of non-congenital, ib.; treatment—mechanical—surgical and mechanical, 661; section of the *rectus femoris*, of *tensor vaginæ femoris*, and *adductor longus*, 661.

LECT. 10.—Angular curvature of the spine, 913; treatment of angular curvature, 916.

Desiderio, M. researches by, upon the poisonous effects of sulphate of quinine, 878.

Dicken's, Mr. case of hæmorrhage from the stomach, and death from swallowing a copper coin, 885.
 Diet and regimen, Dr. Wilkinson's observations on, 799.
 Digitalis, Dr. Munk on the uses of, in diseases of the heart, 257.
 Diseases of the lungs from mechanical causes, Dr. H. M. Hughes on, and Dr. Calvert Holland's account of them, 214, 281.
 Duvernay, M. on the urinary culculi of reptiles, 207.
 Durlacher's, Mr. treatise on corns and bunions, critical notice of, 717.
 Dyspepsia, Dr. Wigan on a form of, 139.

E.

Earle, Mr. J. W. on the distinction between science and practice, 78; on the import of the nervous system in secretion and in irritability, 269, 404, 512.
 Eczema, Mr. B. Phillips on a case of, treated by arsenic and warm water, 721.
 Echinococcus hominis, Mr. Erasmus Wilson on the classification, structure, and development of the, 268.
 EDITORIAL ARTICLES:—
 Our new volume, 26; the commencing medical session, 27.
 The medical profession bill, 53, 91, 201, 232, 291, 388.
 The laudation of the Society of Apothecaries by country practitioners, 55.
 The educational proposals of the Council of the Royal College of Surgeons, 121.
 A manifesto by the Medical and Surgical Association of the borough of Marylebone, 162.
 The resolutions of the Royal College of Physicians, and report of the Royal College of Surgeons of Edinburgh, on the medical bill, 201.
 The dilemma, and remedy the first, 230.
 Address of the Society of Apothecaries, 258.
 Dissimilar views of the proposed medical bill taken by metropolitan and provincial practitioners, 291.
 The dilemma, and remedy the second—association of the general practitioners into a distinct college, incorporated by act of parliament, having an elective council, a court of examiners, and power to frame bye-laws, and to examine and license all future general practitioners, 326.
 The meeting of general practitioners in medicine and surgery of the city of Westminster, 356.

The dilemma, and remedy the third—the practitioner of medicine licensed by a government board, independent of universities. Royal Colleges of Physicians and Surgeons, and Apothecaries' Halls, 385.
 The duties of the state in reference to the practitioner of medicine, 420.
 Advantages of a well constituted council of health and education, 456.
 How is quackery to be remedied? 492.
 Incorporation of general practitioners, 521; schools for the sons of medical men, 523.
 Rumoured changes relative to the College of Surgeons, 551.
 The remedies proposed, 588.
 Means of protection, 614.
 General legislation necessary, 632.
 The question of medicine stamps, 681.
 The new bill, 717.
 The faculty of physicians and surgeons of Glasgow, 738.
 The improper administration of medicines, 777.
 Death from starvation, 803.
 Retrospective effect of the registration clauses, 638.
 Registration of future practitioners, 903.
 On the proposed changes in the profession, 950.
 English and Scotch graduates under the new bill, 968.
 Educational proposals of the council of the Royal College of Physicians and Surgeons, editorial remarks on the, 121.
 Election of fellows of the Royal College of Surgeons, remarks on, by "Veritas," 620.
 Elliot, Dr. on medicine stamps and quackery, 794.
 Empalement, case of, without visceral injury, 846.
 Encephaloid disease of the tibia, Dr. Edwin Hall's case of, 729.
 Enterotomy, lumbar, M. Amussat's case of, without opening the peritonæum, performed with success upon a woman aged 53, 269.
 Epilepsy, Dr. Blackmore's cases of, with remarks on its treatment, 723.
 Ergot of rye, poisoning by bread containing, 877.
 Erysipelas, phlegmonous, Mr. Stafford on two cases of, from wounds poisoned by copper, 829.
 Ethics, medical, 359.
 Evans's, Mr. case of obstruction of the large intestine, 934.
 Evidence, medical, in Belancy's case, Dr. Lethby on the, 213.
 Evolution and delivery, with presentation of the arm and shoulder, Dr. Sussewind's case of, 398.
 Examinations at the University of London and Apothecaries' Hall, 942.

Extirpation of diseased ovaria, Dr. McDowell's cases of, 744.

Eye-ball, Dr. Porter's case of temporary protrusion of the, with loss of vision, from rheumatic inflammation following scarlatina, 704.

F.

Faculty of physicians and surgeons of Glasgow, editorial observations on the proposal to associate it with the university of that city, 738.

Faculty of Glasgow, on the proposal to extinguish this corporation, 780.

Fallot, M. on the action of the heart, 270.

Farrington General Dispensary, Dr. W. Camps, and Dr. W. H. Brown, elected physicians to the, 752.

Fat, the, of animals not an element of respiration, by Dr. George Kemp, 541.

Fearnside's, Mr. H. reports of cases treated in University College Hospital:—Cough of twelve months' duration, and failure of the health during that period, 177; hysteria and spinal irritation, 337; gradual failure of the health for a considerable period, and existence of various symptoms indicating derangement of the cerebral circulation, 529.

Femur, Mr. Lyon on fractures of the, 340.

Fergusson's, Mr. observations on cleft palate, 329.

Fernie, Mr. note from, offering supplies of vaccine lymph, 302.

Fistula in ano, Mr. Lomas on the treatment of, by ligature, 766.

Flourens, M. on the formation of bone, 63.

Fourcault, M. on the functions of the skin, 462.

Frampton, Dr. Algernon, on a very ready and easy manner of ascertaining the specific gravity of urine, 591.

Fungus, case of, from the synovial capsule of the knee, treated by compression, 463.

Fungi, Dr. Lankester on some abnormal forms of, 874.

Furnivall, Dr. on the diagnosis, prevention, and treatment, of diseases of the heart, reviewed, 897.

Furst, Dr. Edward, on the effects of fusel-oil upon the animal economy, 430.

G.

Galen's principal anatomical work, discovery of the nine missing books of, 329.

Gall-bladder, Dr. Somerville Scott Alison on a case of ossification of the, 135.

Galvanic apparatus, best form for a, 592.

Gay, Mr. note from, 96.

General practitioners, probability of their obtaining a charter of incorporation, 383.

General practitioners, remarks on the project for the incorporation of, by "Chirurgus," 519; editorial remarks on, 521.

General practitioners, editorial observations on the means for the protection of, 614; the point discussed as to whether they should be included in the charter of the Royal College of Surgeons, or form a separate incorporation, 652.

Gerdy's, M. case of fungus from the synovial capsule of the knee, treated by compression, 463.

Gintrae's, Professor, case of hypertrophy of the cartilaginous structure of the trachea and bronchi, 32.

Glottis, Mr. Stanhope Illingworth's case of oedema of the, 731.

Goolden, Dr. R. H. on the use of sulphate of manganese in various diseases, 646.

Goodsir's, Messrs. John and D. S. anatomical and pathological observations, reviewed, 736.

Gordon, Dr. Theodore, biographical sketch of, 911.

Gout, Mr. Alexander Ure's researches on, 183.

Graefenberg, or a true report of the water-cure, by H. H. Graham, M.D. 199.

Greatrex, Edward, and Mr. Robinson's case of aneurism of the popliteal artery, 554.

Gregory, Dr. George, on the variolous epidemic of 1844, 617.

Gregory, Professor, on the presence of phosphate of magnesia in bone, and on a new method of procuring phosphoric acid from bone, 390.

Gregory's, Dr. William, outlines of chemistry, reviewed, 678.

Greenhow, Mr. T. M. note from, respecting the case of Miss Martineau, 335.

Greenhow's, Mr. T. M. medical report of the case of Miss H—M—, critical notice of the, 438.

Gulliver, Mr. on the formation of the buffy coat of the blood, 687.

Guy's Hospital, Mr. Hilton elected lecturer on anatomy and physiology at, 304.

Guy's Hospital reports, No. 4, analysis of the, 256, 454.

Guy's, Dr. W. A. principles of forensic medicine, reviewed, 227.

Guy's, Dr. W. A. defence against the charge of plagiarism in his work on forensic medicine, 298.

H.

Hastings, Mr. and Dr. Storks', case of tuberculous excavation of the left lung, treated by perforation of the cavity through the walls of the chest, 378.

- Health, Mr. Fearnside on a case of gradual failure of the, for a considerable period, and existence of various symptoms indicating derangement of the cerebral circulation, 529.
- Health and education, advantages of a well-constituted council of, 456.
- Head, case of injury to the, 271.
- Heart, Dr. Somerville Scott Alison on a case of hypertrophy of the, 135.
- Heart, M. Fallot on the action of the, 270.
- Headache, Mr. T. Wilkinson King on the seat of, and its import in diagnosis, 412.
- Heberden, the late Dr. memoir of, 972.
- Helmuth's, Dr. case of retroversion of the womb in the unimpregnated state, 717.
- Hepatalgia, Dr. Allnatt on, 796.
- Hernia, strangulated, case of, for which an operation was performed by Mr. B. Phillips, 722.
- Hewett, Mr. Prescott, on extravasation of blood into the cavity of the arachnoid membrane, 684.
- Hilton, Mr. John, elected lecturer on anatomy and physiology at Guy's Hospital, 304.
- Hip, Mr. Arnott's clinical lecture on a case of disease of the, 403.
- Hocken, Dr. on a case of immense accumulation of hardened feces in the rectum, and complete suppression of the alvine evacuations for a month, 530.
- Hocken's, Dr. practical remarks on the value of the operation of perforating the wall of the chest into a tubercular cavity for the relief or cure of tubercular phthisis, 431.
- Hoffmann, Dr. the combination of alum and opium recommended by, in cases of lead colic, 207.
- Homicide by an unqualified practitioner, 656.
- Home, Dr. of Edinburgh, notice of the death of, 368.
- Hooping-cough, Mr. Streeter on the nature and seat of, 195.
- Hôtel Dieu, surgery of the, 367; remarks on, by "Chirurgus Britannicus," 458.
- Hufeland, Professor, on the relations of the physician, 543, 580.
- Hughes, Dr. H. M. on diseases of the lungs from mechanical causes, and Dr. Calvert Holland's account of them, 214, 281.
- Hunter, Dr. William, Dr. Robert Lee's discourse on the life and labours of, 1.
- Hunt's, Dr. observations on the relaxed rectum, 332.
- Hydatid tumor of the liver, Dr. Somerville Scott Alison's case of, 18.
- Hydrocele, case of, of the hernial sac, cured by external treatment, 61.
- Hydrocele, Mr. Burton's case of, 974.
- Hydrocephalus, Dr. Edward Blackmore on the treatment of, 699.
- Hydrocyanic acid, Dr. Allnatt on ergotization of the tipulidæ by, 675.
- Hydrocyanic acid, Mr. Pooley's case of poisoning by, 859.
- Hygiene, contributions to, with particular reference to the soldier, 104, 108.
- Hymen, imperforate, Dr. Rebfield on a case of, 461.
- Hypertrophy of the cartilaginous structure of the trachea and bronchi, 32.
- Hysteria, and "spinal irritation," Mr. Fearnside's report of a case of, 337, 373.

I.

- Ideal physiology, a specimen of:—Carrus's earth-life, 33.
- Imperforate anus, curious malformation connected with, 733.
- Illingworth's, Mr. Stanhope, case of œdema of the glottis, 731.
- Incorporation of general practitioners, remarks on, by Medicus, 428.
- Incorporation of general practitioners, remarks on the project of, by Chirurgus, 519; editorial remarks on, 521.
- Incorporation of general practitioners, remarks on the, and the Medical bill, by Medicus, 233.
- Insanity, case of sudden access of, 878.
- Iodide of potassium, Mr. Tatum's three cases of hard circumscribed tumors disappearing under the use of, 591.
- Irregular practitioners, danger of, to the public, 129.
- Is the medical profession over- or understocked? 620.

J.

- Jaw, the lower, Dr. Chisholm's case of excision of nearly one half of the, 46.
- Jeaffreson, Dr. S. J. on the pathology and treatment of ovarian diseases, 44, 80, 112.

K.

- Kaemtz's complete course of meteorology, review of, 355.
- Kemp, Dr. George, on the functions of the bile, 76; on the theory of respiration, 319; paper by, shewing that the fat of animals is not an element of respiration, 541.
- Key's, Mr. Aston, case of aneurism of the right sub-clavian artery, 334.
- King, Mr. T. W. on the capillary circulation of the face and head, 62, 232.
- Kingdom, Mr. on a case of rupture of the liver, 879.

- Kneejoints, Mr. Stanley on a case of extreme contraction and immobility of the, 99.
- Köhler's, Dr. case of laceration of the rectus femoris muscle, 303.
- Krafft's, Dr. case of poisoning by arsenic, treated with hydrated oxide of iron, 750.
- Krieger, Dr. on the course of medical study in Sweden, 206.
- L.
- Labour, case of, complicated with recto-vaginal hernia, 926.
- Lambrecht, Dr. on a case of necrosis of the scapula, 240; case of ovarian dropsy discharging itself by the umbilicus, 303.
- Lancker, Dr. Edwin, on some abnormal forms of fungi, 874.
- Larynx and trachea, Mr. Stanley on the treatment of transverse divisions of the, 97.
- Lassaigne's, M. observations on the composition of a new species of calculus found in the kidneys and the ureters of a bitch, 622.
- Lead colic, the combination of alum and opium recommended by Dr. Hoffman in cases of, 207.
- Lecluyse, Dr. on a case of singular deformity of the womb inducing arm presentation of the child in three consecutive labours, 847.
- Le Conte, Dr. John, on the extraordinary effects of a stroke of lightning, 782.
- Lee's, Dr. Robert, discourse on the life and labours of Dr. William Hunter, delivered at the opening of the session, 1844-5, in the theatre of St. George's Hospital, 1; on the structure of the corpus luteum as a test of early pregnancy, 150; correction of some misstatements respecting the placenta, menstruation, and the corpus luteum, 847.
- Lee, Mr. Edwin, note from, and protest against the omission of his name from the List of Fellows of the Royal College of Surgeons, 175; notice of the medical organization, studies, &c. in Italy, 348, 437, 574.
- Lee's, Mr. account of a case of encysted empyema of twelve years' standing, 890.
- Lefevre's, Sir George, apology for the nerves, reviewed, 290.
- Letheby, Dr. on a case of poisoning with oxalic acid, 49; on the medical evidence in Belaney's case, 218; on a case of poisoning by opium, 247; on the poisonous effects of the cyanides, 603, 676; on the late case of poisoning by prussic acid, 972.
- Limosis avens, small stomach, Dr. Somerville Scott Alison on a case of, 135.
- Linsem's, Dr. case of amnesia complicating acute rheumatism, 304.
- Lion, Dr. on a curious case of paralysis, 208; on a case of poisoning with mortar or quicklime, 64; on a case of melancholia puerperalis attonita, 303.
- Lithotomy, Dr. A. Arnott's description of an operation for, performed by a native hakeem, 621.
- Liver, Dr. Somerville Scott Alison's case of hydatid tumor of the, 18.
- Liver, Dr. Paterson's case of inflammation of the, 538.
- Lock-jaw, with tumor of the jaw, cases treated by Mr. Benjamin Phillips, 433.
- Lomas, Mr. on the treatment of fistula in ano, by ligature, 766.
- London hospital report:—case of hydrocele of the hernial sac, cured by external treatment, 61; case of varicocele treated by compression, ib.
- London Medical Directory, notice respecting the publication of the, 388.
- London Medical Directory for 1845, critical notice of the, 802.
- Lumbricus, discharge of a, from the male urethra, 912.
- Lungs, Dr. H. M. Hughes on diseases of the, from mechanical causes, and Dr. Calvert Holland's account of them, 214.
- Luxation of iliac bone upon the sacrum, two cases of, 814.
- Lyon, Mr. W. on fractures of the femur, 340, 337, 373.
- M.
- Macdonnell, Mr. on a peculiar form of dissecting aneurism of the thoracic aorta, 768.
- Macpherson, Mr. John, on tumors of cicatrices, 346.
- Macilwain's, Mr. address on the occasion of the anniversary meeting of the Royal Medical and Chirurgical Society, 744.
- Malformation of the genital organs, case of, 943.
- Marx's, Dr. Acesius, a survey of the ethical relations of medicine, 14, 51, 87, 102, 113, 184.
- Martineau's, Miss, letters on mesmerism, notice of, by "Veritas," 426.
- Marylebone Manifesto, remarks on the, by "An Old Admirer," 238.
- Mayo's, Dr. record of cases:—complication of thoracic with cerebral congestion, 17; on bleeding in cases of congestion, 146; chronic cases, treated with partial or entire success, in which morbid changes of the cerebral or spinal system have existed, or have been threatened, 332; cough, with occasional hæmoptysis, 485; scarlatina, 923.
- Meade's, Mr. R. H. clinical observations on surgery, 895.

- Medical reform bill, letters from correspondents on the subject of the:—From "An Old Practitioner," 29; resolutions relative to the, adopted by the Royal College of Physicians of Edinburgh, 166; report by the Royal College of Surgeons of Edinburgh, 167.
- Medical organization, studies, &c. in Italy, Mr. Edwin Lee's account of the, 348, 437, 574.
- Medical profession, remarks on the numerical relation of, to the population of Great Britain, 620.
- Medical testimony, on the value of, 683.
- Medical Missionary Society of Edinburgh, 805.

- Miller's, Mr. James, principles of surgery, reviewed, 89.
- Military surgery, Sir George Ballingall's outlines of, reviewed, 547.
- Miling, Dr. on a case of death from internal hæmorrhage after a violent effort, 207.
- Moore's, Mr. prize essay on the structure of the lungs, reviewed, 803.
- Mortality, Mr. Clay on the influence of burial clubs on, 209.
- Mortality of the metropolis, tables exhibiting the, 32, 64, 96, 272, 304, 336, 368, 400, 432, 464, 528, 560, 592, 624, 656, 688, 720, 756, 816, 848, 880, 912.
- Mortimer's, Mr. observations on the growth of children's teeth, reviewed, 927.
- Movement in the profession, respecting the new medical bill, proceedings of the various meetings throughout the country: at Rochester, 29; memorial of the medical profession at Liverpool, 58; meeting of medical men at Devonport and Stonehouse, 59; of the Gloucestershire Medical and Surgical Association, ib.; proceedings at a meeting of the Council of the British Medical Association, 60; meeting at Salisbury, 94; at Bristol, ib.; Dr. Symonds' address on the occasion, ib.; meeting at Kensington, 95; at Wrexham, 96; at Bradford, 124; at Chester, ib.; at Shrewsbury, 125; at Colchester, ib.; at Dover, 164; at York, ib.; at Gravesend, 165; at Newcastle, ib.; report of the Council of the Glasgow Medical Association on the bill, 234; meeting of the profession at York, 235; of Chichester, 236; of Bath, ib.; of Northampton, 262; of Maidstone, 263; of Blackburn, 296; of Warrington, ib.; of the Taunton and Somerset branch of the Medical and Surgical Association, 361; meeting at the Hanover Square Rooms, 362; at Sunderland, 387; protest of the practitioners of Surrey, 458; at Cambridge, 525; at Aylesbury, ib.; meeting of the Faculty of Physicians and Surgeons of Glasgow, 353; of the medical profession of Ulverston and Lonsdale, ib.; petition from the county of Hertford, 554; protest from East Kent, ib.; meeting at Gloucestershire, 854; proceedings of the Association of General Practitioners in Medicine, Surgery, and Midwifery, ib.; meeting of members of the college practising in Hampshire, 682; meeting at York, 848; protests from Manchester and Salford, 848; memorial of the Woolwich practitioners, 874; meeting of the Birmingham and Midland Districts Medical and Surgical Association, 875.

- Mülder, Dr. on the chemistry of vegetable and animal physiology, reviewed, 774.
Munk, Dr. on the action of digitalis, and its uses in diseases of the heart, 257.

N.

- Naphtha in phthisis, remarks on the employment of, by "An Old Practitioner," 543.
Nerves, Mr. J. W. Earle on the influence of the, on secretion, 404, 512.
Nervous system, Mr. J. W. Earle on the import of the, in secretion and in irritability, 278.
Nervous system, Dr. Edward Blackmore's observations upon the more important diseases of the, with illustrative cases, 557, 569, 630, 671, 699, 723, 760, 789, 822, 855, 917, 954.
Neuroses, Dr. Pidduck on the periodicity of, 556.
Nevins, Mr. on the best method of finding the specific gravity of powders, 226.
Newnham, Mr. on human magnetism, reviewed, 777.
Norblad's, Mr. E. W. account of the post-mortem examination of Sarah Hart, alleged to have been poisoned at Salt Hill, 518.

O.

- Oath taken by members of the Royal College of surgeons, 941.
Oedema of the glottis, Mr. Henry Stanhope Illingworth's case of, 731.
Ophthalmitis, phlegmonous and phlebitic, Dr. Mackenzie's notes of a lecture on, 593.
Opium a hazardous remedy in strangulated hernia, 781.
Opium, Dr. Letheby on a case of poisoning by, 247.
Orthopedic institution, note from the Secretary of the, 334.
Our new volume, remarks on the commencement of, 26.
Ova, the periodical maturation and extrusion of, independently of coitus, in mammalia and man, proved to be the primary condition to their propagation, Mr. Henry Smith's translation of Bischoff's paper on, 443, 503, 694, 951.
Ovaria, diseased, Dr. Ephraim McDowell's cases of extirpation of, 744.
Ovarian dropsy, Dr. Lambrecht's case of, discharging itself by the umbilicus, 303.
Ovarian diseases, Dr. S. J. Jeaffreson on the pathology and treatment of, 44, 80, 102.

- Oxalic acid, Dr. Letheby's case of poisoning by, 49.
Oxalate of lime, Dr. Golding Bird's notice of the discovery of the, in the urine of herbivora, 49.

P.

- Paterson's, Dr. case of inflammation of the liver, 538; on the structure of the corpus luteum, 640.
Paterson's, Mr. remarks on a case of uterine hæmorrhage, 47; on the early application of the child to the breast, 811.
Paracentesis thoracis, Dr. Thorston's successful case of, 431.
Paralysis, curious case of, related by Dr. Lion, 208.
Peacock, Dr. on a case in which the vena cava inferior was obstructed from the commencement of the common iliac arteries, 267.
Pectoral disease, Dr. T. Ogier Ward's case of, 148.
Pericarditis, Dr. Somerville Scott Alison on, a complication and sequela of scarlatina, with cases and observations, 864.
Pericarditis, Dr. Alison on the occurrence of, in scarlet fever, 728.
Peschel's, Mr. elements of physic, reviewed, 737.
Phillips, Mr. Benjamin, case of lock-jaw treated by, 433.
Phthisis, tubercular, Dr. Hocken's practical remarks on the value of the operation of perforating the wall of the chest for the relief or cure of, 481.
Phthisis, remarks on the employment of naphtha in, by "An Old Practitioner," 543.
Phthisis in Cetacea, 879.
Physicians, registered, on the right of, to practise in London under the new bill, 750.
Physical Society of Guy's Hospital, proceedings of the:—The President's address, *ib.*; Mr. Wilkinson King on the capillary circulation of the face and head, *ib.*; Mr. Cole on a case in which a foreign body was impacted in the throat, 127; Mr. Streeter on the nature and seat of whooping-cough, 205; Dr. Barlow on the depuration of the blood, 259; Mr. Key's case of aneurism of the right subclavian artery, 334.
Physician, Professor Hufeland on the relations of the, 543, 580.
Pidduck, Dr. on the periodicity of neuroses, 556.
Points of practice, by Dr. A. L. Wigan, 224.
Poisoning, Dr. Letheby's case of, with oxalic acid, 49.

Poisoning with mortar or quicklime, 64.
 Poisoning with radix sambuci, 96.
 Poisoning, alleged case of, at Salt Hill, Mr. E. W. Nordblad's account of the post-mortem examination of the body, 518.
 Poisoning by arsenic, Dr. Kraft's case of, treated with hydrated oxide of iron, 750.
 Poisoning by bread containing ergot of rye, 877.
 Poisoning by carbonate of lead, Mr. John Snow's case of, 248.
 Poisoning by sulphuric acid, case of, 876.
 Poisoning, case of, by prussic acid, communicated by Mr. Hicks and Mr. Waterworth, 893.
 Polar expedition, the new: the Admiralty's treatment of their medical officers, 583.
 Polypus of the bladder, Dr. Thienemann's case of ligature of the, 175.
 Pooley's, Mr. case of poisoning by hydrocyanic acid, 859.
 Poor, Dr. Somerville Scott Alison on the state of the, in Scotland, 310.
 Porter's, Dr. case of temporary protrusion of the eyeball, with loss of vision, from rheumatic inflammation following scarlatina, 704.
 Porter, Mr. on the treatment of district medical officers by Boards of Guardians, 734.
 Powders, Mr. Nevins on the best method of finding the specific gravity of, 226.
 Practitioners of medicine, editorial observations on the duties of the state in reference to, 426.
 Pregnancy, Dr. Lee on the value of the corpus luteum as a test of, 150.
 Prisons, Dr. W. Baly on the mortality in, and the diseases most frequently fatal to prisoners, 740.
 Prussic acid, case of poisoning by, communicated by Mr. Hicks and Mr. Waterworth, 893.
 Purpura hæmorrhagica, Mr. Henry Smith on the treatment of, 559.
 Pus-cells, Mr. Addison on the transformation of, into a mucous or fibrous tissue, 70, 250.

Q.

Quackery, remarks on the suppression of, 264.
 Quackery, prime obstacle to the suppression of, 387, 424; the remedy for, considered, 492.
 Quack medicines, advertisements of, 296.
 Quain's, Dr. anatomy of the arteries of the human body, reviewed, 586.
 Quarantine, remarks on, as applied to the prevention of the plague, by M. Aubert Roche, 879.

Quicklime, case of poisoning by, 64.
 Quiescence by adhesion, 751.

R.

Radix sambuci, case of poisoning by, 96.
 Radford's, Mr. lecture on the application of galvanism to the treatment of hæmorrhage, 490.
 Rectus femoris muscle, Dr. Köhler's case of laceration of the, 303.
 Recruiting, statistics of, in the districts of Great Britain and Ireland, during 1844, 550.
 Rees's, Dr. G. O. Gulstonian lectures delivered at the Royal College of Physicians:—on the blood, principally in regard to its physical and pathological attributes, 753, 826, 849.
 Registration clauses, editorial observations on the retrospective effect of the, 868.
 Registration under Sir James Graham's new bill, correspondence between Mr. Craddock and the Home Office, 813.
 Rehfeld, Dr. on a case of imperforate hymen, 462.
 Relaxed rectum, Dr. Hunt on the, 332.
 Respiration, Dr. George Kemp on the theory of, 319.
 Resolutions of the College of Physicians, and report of the Royal College of Surgeons of Edinburgh on the Medical Bill, editorial observations on the, 201.
 Retroversion of the womb, Dr. Helmuth's case of, in the unimpregnated state, 747.
 Re-vaccinations, results of the, performed in the Prussian Army in the year 1843, 461.
 Rigg's, Mr. experiments on the formation or secretion of carbon on animals, the disappearance of hydrogen and oxygen, and the generation of heat during the process, 220.
 Roberts, Dr. on a case of ulceration of the duodenum, 266.
 Royle, Dr. on the importance of the study of chemistry, 780.
 Royal Medical and Chirurgical Society, papers read at the:—
 Mr. Roberts on a case of ulceration of the duodenum, 266.
 Dr. Peacock on a case in which the vena cava inferior was obstructed from the commencement of the common iliac veins, 267.
 Mr. Erasmus Wilson on the classification, structure, and development of the echinococcus hominis, 268.
 Dr. Hocken on a case of immense accumulation of indurated feces in the rectum, with complete suppression of the alvine evacuations for a month, 330.
 Dr. Hunt's observations on the relaxed rectum, 332.

- Mr. Fergusson's observations on cleft palate, and on staphylography, 389.
- Messrs. Greatrex and Russell's case of aneurism of the popliteal artery cured by compression of the femoral artery, 554.
- Dr. Pidduck on the periodicity of neurones, 556.
- Mr. Tatum's three cases of hard circumscribed tumors in muscle, disappearing under the influence of iodide of potassium, 591.
- Dr. Gregory on the variolous epidemic of 1844, 617.
- Mr. Prescott Hewett on extravasation of blood into the cavity of the arachnoid membrane, 684.
- Mr. Gulliver on the formation of the buffy coat of the blood, 687.
- Dr. Baly on the mortality in prisons, and the diseases most frequently fatal to prisoners, 740.
- Notice of Mr. Macilwain's address at the anniversary meeting, 744.
- List of the officers for 1845-6, ib.
- Mr. Stanley on the pulsatory tumors of bone, 806.
- The President's address, 808.
- Mr. Rainey on the minute structure of the lungs, and the formation of pulmonary tubercle, 871.
- Dr. Davy on the colostrum of the cow, 933.
- Mr. Evans's case of obstruction of the large intestine, 934.
- Royal College of Surgeons of England, gentlemen admitted members of the, 32, 64, 176, 208, 272, 368, 464, 592, 656, 688, 734, 880, 912, 944, 976.
- Royal College of Surgeons of England, list of members admitted to the Fellowship on the 24th of December, after passing the required examination, 560.
- Royal College of Surgeons, reply of the, to the National Association of practitioners in medicine, surgery, and midwifery, 905.
- Royal College of Surgeons of Edinburgh, the rumour of an intention to dispose of the museum contradicted, 425, 495.
- Royal College of Physicians, proposed charter of the, statement regarding the licentiates *extra urbem*, 909.
- Royal Society, last soirée of the, for the season, 910.
- Rumoured changes relative to the College of Surgeons, editorial observations on the, 551.
- Rupture of the liver, Mr. Kingdom on a case of, 879.
- S.
- Sages-femmes in Paris, regulations respecting, 877.
- Saunders, Mr. on the treatment of tooth-ache, 975.
- Spleen, case of rupture of the, 943.
- Stafford, Mr. R. A. on tetanus, or locked-jaw, and its treatment, 945.
- St. Marylebone Infirmary, Mr. Stafford's report of surgical cases treated in the, 638.
- St. Marylebone Infirmary, decision of the Guardians with respect to the vacant surgeoncy, 425.
- St. Marylebone Infirmary, remarks by "Philistrus" on the propriety of the determination to discontinue gratuitous medical services, 528; further remarks, by "Philojustitia," 558.
- Salerno, account of a visit to, 31.
- Sanatorium, the, mesmerism not sanctioned nor practised by any of the medical gentlemen connected with the institution, 425.
- Scarlet-fever, Dr. Alison on the occurrence of pericarditis in cases of, 728.
- Scapula, Dr. Lambrecht's case of necrosis of the, 240.
- Schoenlein's, Dr. clinical lectures, review of, 866.
- Schollmeyer's, Dr. case of poisoning by radix sambuci, 96.
- Schools for the sons of medical men, editorial observations on the proposal for the establishment of, 523.
- Science and practice, Mr. J. W. Earle on the distinction between, 78.
- Secretion, Mr. J. W. Earle on the influence of the nerves on, 404, 512.
- Serous membranes, Dr. Willis on the import and office of the, 767.
- Sewers, cess-pools, &c. M. Siret's disinfectant for, 176.
- Shoulder-joint, Mr. Collier's case of accident to the, 925.
- Skin, M. Fourcault on the functions of the, 462.
- Small-pox, susceptibility to, after vaccination, 461.
- Small-pox, malignant or hæmorrhagic, Dr. John Snow's case of, 586.
- Smee's, Mr. case of copper-coloured syphilitic eruption affecting the conjunctiva, 347.
- Smee, Mr. Alfred, on vessels in fat smaller than the capillaries, 874.
- Smith's, Mr. Henry, translator of a memoir by Professor Bischoff, on the periodical maturation and extrusion of ova, independently of coitus, proving it to be the primary condition to their propagation, 443, 506, 694, 961.
- Smith's, Mr. William, case of abscess in the abdominal muscles, and diseased pubic bones, 517.
- Smith, Mr. Henry, on the treatment of purpura hæmorrhagica, 559.
- Snow's, Mr. John, case of acute poisoning by carbonate of lead, 248.
- Snow's, Dr. case of malignant or hæmorrhagic small-pox, 586.

- Snow, Dr. John, on pericarditis after scarlet fever, 728.
- Society and the Doctors, 559.
- Society of Apothecaries, laudation of the, by country practitioners, 55.
- Society of Apothecaries, editorial observations on the address of the Society of, 834.
- Society for the relief of widows and orphans of medical men, changes of the officers for the, 128.
- Society for the relief of widows and orphans of medical men, half-yearly meeting of the, 205.
- Solly, Mr. on the protective apparatus of the brain and spinal cord in man and animals, 936.
- Solly's, Mr. contributions to the pathology of the brain, 245; on diseases of the spine, 625, 689.
- Soulby, Mr. George, on the importance of duly qualified chemists and druggists to the profession, 128.
- Stanley's, Mr. clinical lectures delivered at St. Bartholomew's Hospital:—
Treatment of transverse divisions of the larynx and trachea, 97.
Subcutaneous division of tendons, 98.
Talipes equinus in both limbs of an adult, from rigidity and shortening of each tendo-achilles, gradually arising without obvious cause, division of the tendons, 98.
- Extreme contraction and immobility of the knee-joints, limited motion of the ankle-joints, consequent on paraplegia—division of the ham-strings, and tendo-achilles in each limb, 99.
- Compound dislocation of the last joint of the thumb, of the obstacle to its reduction, 100.
- Subcutaneous encysted tumor, containing the acephalocyst hydatid, echinococcus, 101.
- Diagnosis of fracture, 273.
- Adjustment of fractures, 274.
- Fractured ends of the bone impacted together the obstacle to adjustment, 275.
- Fracture of a bone in two places the obstacle to adjustment, 275.
- Displacement of a tendon or muscle the obstacle to adjustment, 275.
- End of the bone impacted in the substance of an adjacent muscle the obstacle to adjustment, 275.
- Inordinate action of the muscles on one side of the limb, consequent on the laceration of those on the opposite side, their antagonists, displacing the fractured bone, and constituting an insuperable obstacle to its adjustment, 275.
- Treatment of fractures which are slow of union, 276.
- Influence of the action of the muscles around the slowly uniting fracture, 276
- Influence of pressure upon the ununited fracture, 276.
- On the use of the immoveable apparatus, 277.
- Stanley, Mr. on the pulsatory tumors of bone, 809; his address at the anniversary meeting, 808.
- Stafford's, Mr. R. A. report of surgical cases treated by him in the St. Marylebone Infirmary, 638, 827; on tetanus, 935.
- Starvation, editorial observations on a case of death from, 803.
- Sternum, case of congenital deficiency of the, 208.
- Strauss's, Mr. remarks and comments on the medical and chemical evidence adduced at the trial of John Tawell, critical notice of, 360.
- Strangulated hernia, opium a hazardous remedy in, 781.
- Streeter, Mr. on the nature and seat of whooping-cough, 195.
- Sweden, Dr. Krieger on the course of medical study in, 206.
- Sulphate of manganese, Dr. R. H. Gool ten on the employment of, in various diseases, 646.
- Sussewend's, Dr. case of evolution and delivery, with presentation of the arm and shoulder, 398.
- Subjects for dissection, dearth of, 236.
- Suffert, Dr. on a case of anaurosis occurring suddenly, 240.
- Sulphuric acid, poisoning by, 878.
- Sulphate of quinine, researches upon the poisonous effects of, by M. Desiderio, 878.
- Superfecundation (?) in a sow, 464.
- Surgery, Mr. R. H. Meade's clinical observations on, 958.
- Surgical operations, remarks on a proposed application of mesmerism to, 557.
- Surgery of the Hôtel Dieu, 367; remarks on the, by "Chirurgus Britannicus," 459.
- Sydenham Society, hints to the, 126.
- Synnot's, Dr. case of sudden blindness, 160.
- Syphilitic eruption, case of copper coloured, affecting the conjunctiva, 347.
- Syphilis, Mr. Thomas Bartlett on, particularly the treatment of the primary sore, 73.

T.

- Talipes equinus in both limbs of an adult, Mr. Stanley on a case of, 98.
- Tamplin's, Mr. lectures on the nature and treatment of deformities.—See "Deformities, Mr. Tamplin's lectures on the nature and treatment of."
- Tatum's, Mr. three cases of hard circumscribed tumors in muscle disappearing under the influence of iodide of potassium 591.

- Taylor, Mr. Alfred, on a case in which death followed an over dose of opium administered to a child, 256; note from, respecting a review of Dr. Guy's principles of forensic medicine, 335; on the numerical relation of the medical profession to the population of Great Britain, 497; thermometrical table, on the scales of Fahrenheit, Centigrade, and Reaumur, 587.
- Tendons, Mr. Stanley on the subcutaneous division of, 98.
- Tetanus, Mr. Stafford on a case of, the symptoms of which resembled hydrophobia, 827.
- Tetanus, or locked-jaw, and its treatment, Mr. R. A. Stafford on, 945.
- Therapeutical inquiry, Dr. James Arnott on the present state of, 407, 474, 481.
- Thermometer, a moral and physical, 52.
- Thermometer, state of the, during January 1845, 624; during Feb. 752.
- Thermometrical registers, defects of, 781.
- Thienemann's, Mr. case of ligature of a polypus of the bladder, 175.
- Thigh-bone, luxation of the head, and fracture of the neck of the, 367.
- Thompson, Mr. on a singular case of fatal intra-uterine hæmorrhage, 289.
- Thorston's, Dr. successful case of paracentesis thoracis, 431.
- Thornton, Dr. on the use of creasote in nævus maternus, 176.
- Thumb, Mr. Stanley on a case of compound dislocation of the, 100.
- Tibia, Dr. Edwin Hall's case of encephaloid disease of the, 729.
- Tierney's, Sir J. Matthew, observations on variola vaccina, reviewed, 868.
- Tipulidæ, Dr. Allnatt on ergotization of the, by hydrocyanic acid, 675.
- Topography, medical, of the Bights of Benin and Biafra, Mr. W. F. Daniell's observations on the, 435, 515, 582, 643, 706, 771, 886.
- Transactions of the College of Physicians at Philadelphia, summary of the, 747.
- Tuberculous excavation of the left lung, treated by perforation of the cavity through the walls of the chest, 378.
- Tumour, subcutaneous encysted, containing the acephalocyst hydatid, echinococcus, Mr. Stanley on a case of, 101.
- Tumors of cicatrices, Mr. Macpherson on, 346.
- University College, second examination for the degree of A.M., 272.
- University of London, examiners appointed in the room of Professor Daniell, 912.
- University of St. Andrew's, 623.
- University of London, list of gentlemen who have passed the examination for doctor of medicine, 431; for bachelor of medicine, 432.
- Ure's, Mr. Alexander, researches on gout, 188; record of cases treated at the Westminster General Dispensary, 785.
- Uric acid excreted by butterflies, 623.
- Urine, Dr. Frampton on a very easy and ready manner of ascertaining the specific gravity of, 591.
- Urinary calculi of reptiles, M. Duvernoy on, 207.
- Urinary deposits, Dr. Golding Bird's work on, reviewed, 419.
- Uterine hæmorrhage, Mr. Paterson's remarks on a case of, 47.
- Uterine hæmorrhage, Mr. Thompson on a singular case of, proving fatal, 289.
- V.
- Vaccine lymph, note from Mr T. P. Fernie, 302.
- Vaccination, susceptibility to small-pox after, 460.
- Valerianate of zinc, cases in which it may be advantageously employed, 623.
- Variocoele, case of, treated by compression, 61.
- Ventilation, insufficient, of the Royal Medical and Chirurgical Society, complaints respecting the, 329.
- Visit to Salerno, account of a, 31.
- W.
- Wagner's, Dr. elements of the comparative anatomy of the vertebrate animals, reviewed, 649.
- Ward's, Dr. T. Ogier, case of pectoral disease, 143.
- Water, Dr. Wilkinson on the medical agency of, at different temperatures, 770.
- Westminster General Dispensary, Mr. Alexander Ure's record of cases treated at the, 785.
- Westminster Hospital, cases treated by Mr. Benjamin Phillips in, 433, 721.
- Wigan, Dr. A. L. on a form of dyspepsia, 139; on points of practice—offensive breath, 224.
- Wilczewski, Dr. on the terchloride of gold as an outward application in rheumatic gouty affections, 751.
- Wilkinson, Dr. on the medical agency of water at different temperatures, 770.
- U.
- University College, second examination for the degree of A.M., 272.
- University of London, examiners appointed in the room of Professor Daniell, 912.

- Willis, Dr. on the import and office of the serous membranes, 767.
- Wilson, Mr. Erasmus, on the classification, structure, and development of the echinococcus hominis, 268.
- Wilkinson's, Dr. observations on diet and regimen, 799.
- Wells's, Dr. essay upon cretinism and goitre, reviewed, 868.
- Wöhler, Professor, remarkable case of poisoning with arsenic related by, 655.
- Womb, Dr. Helmuth's case of retroversion of the, in the unimpregnated state, 747.
- Woolwich practitioners, memorial of the, 875.
- Wounds of blood-vessels, M. Amussat's researches on the, 496.
- Womb, singular deformity of the, inducing arm presentation of the child in three consecutive labours, 847.
- Wounding, notice of a trial for, 937.
